SAVOY, or **SAVOIE,** sä-vwä, France, consists of two eastern departments, Savoie and Haute-Savoie, formed in 1860 out of the former duchy of Savoy, one of the states of the Sardinian monarchy (q.v.); it covers an area of 4,162 square miles (2,388 in Savoie and 1,774 in Haute-Savoie), and is exceedingly mountainous. The region is separated from Switzerland by Lake Geneva and is dominated by Mont Blanc, the loftiest peak of the Alpine chain, whose many ramifications extending in all directions present a relief of successive mountains and valleys. Savoy belongs to the Rhone basin, which forms its western boundary. The other rivers are the Arve, Isère and Arc. The chief lakes besides Geneva are those of Bourget and Annecy. The climate is, generally speaking, cold. Savoy is rich in mineral waters, of which the most famous are those of Aix-les-Bains (hot-sulphur), Marlioz, Challes (strong natural sulphur), Salins-Montiers (hot, saline, various minerals), Brides-les-Bains (soda, calcium). The extent of arable ground is limited, but a scarcity of grain is supplied by the chestnut which forms a staple food among the peasants and the poor. The vine is somewhat cultivated in the lower valleys and slopes. The main source of profit is in the cattle and dairy produce, as hay and pasture alone are obtained from much of the land. The forests, which cover vast mountain slopes, also afford a rich supply of timber. The minerals are not sufficiently exploited to be of any importance. The manufactures are coarse woolens, linen and cotton goods, felt hats, leather and hardware. Other industries are silk, tanning and weaving. There is an important transit trade carried on between France and Italy, by way of Mont Cenis. Coal, skins, cotton, provisions are imported; cattle, dairy produce, wood, stones, mineral waters, silk goods, tanned leather and paper are exported. There are some schools, all speak French and they are exclusively Roman Catholic. The University Academy is at Chambéry, and clock-making is taught in two special schools at Annecy, employing 2,000 hands. (Here is also a large cotton mill). The inhabitants are industrious, honest, hospitable and intelligent; their chief characteristic, however, is love of country. Though often compelled to leave their homes for winter employment, wandering through France, Switzerland, Spain, or Italy, in order to earn a livelihood, they return to their native mountains at the earliest moment. Sardinia ceded Savoy to France in 1860. It was formed into the two departments of Savoie and Haute-Savoie, whose capitals are respectively, Chambéry and Annecy. Pop. Haute-Savoie 252,794; of Savoie about 235,544; total, 488,338.

SAVOY CABBAGE, a variety of cabbage (q.v.) with many sub-varieties, forming large close heads with wrinkled leaves, and cultivated for winter use, requiring a light, rich soil.

SAVOY CONFERENCE, a conference held in 1661 at the Savoy Palace, London, between a number of Church of England and Presbyterian divines for the purpose of "advising upon and reviewing the Book of Common Prayer; and of taking into serious consideration the several directions and rules, forms of prayer, and things in the same book;

of consulting also upon the several objections which shall now be raised against the same; and, if occasion need be, to make such necessary and reasonable alterations, corrections and amendments as shall be agreed upon to be needful and expedient for the giving satisfaction to tender consciences, and the restoring and continuing of peace and unity in the churches under his majesty's government and protection.» When the Parliamentary cause triumphed in the civil war of 1642–46 the majority of the clergy, who were royalists, were either turned out of their pulpits and their places were filled by Presbyterians, then a strong body in England; and at the Restoration of Charles II a large number of the ministers connected with the church strongly objected to Episcopalian order and practice being again introduced. The government was fully aware of this state of matters, and it was accordingly resolved that the determination of all matters appertaining to the establishment of unity should be left to the advice of a national synod. On 25 March 1661, therefore, the letters-patent above quoted from were issued, appointing 12 bishops, with nine clergymen as assistants on the Episcopal side, to meet with an equal number of Presbyterian divines and discuss the matters therein mentioned. The commissioners met for the first time on 13th April. Sheldon opened the discussion by observing that the Episcopal party, being perfectly satisfied with the established forms of worship, had nothing to propose, and would therefore expect that any objections to the existing order of things, and any innovations that might be desired, should be mentioned by their opponents. The Presbyterians moved that Bishop Ussher's Reduction of Episcopacy, a scheme in which the elements of the Scotch system of presbyteries, synods and general assemblies were combined with distinctions of ecclesiastical ranks, should be laid down as a ground-work to treat upon. They further offered several exceptions to the liturgy, against the many responses of the people, and desired that all might be made one continued prayer. They objected to lessons being taken out of the Apocrypha, and wished that the psalms used in the daily service should be according to the new translation. They excepted to many parts of the baptismal service that infer the doctrine of the regeneration of the baptized. They also moved that the practice of kneeling at the Lord's Supper, and that the use of the surplice, the cross in baptism, of godfathers as sponsors, and the celebration of the holy days, should be abolished. It was urged in reply to the demand for the adoption of Ussher's scheme, that the king's commission gave them no power even to take into consideration any questions relating to the government of the church; and the Presbyterians proceeded to discuss the minor points, mainly the alterations in the liturgy. Baxter undertook the preparation of what was called a Reformed Liturgy, but the Episcopalian commissioners rejected it at once, without examining it. The two parties finally separated at the end of four months, the period assigned by the letters-patent, without coming to a single resolution, and the government passed in the following year the famous act of uniformity, the stringent clauses of which drove about 2,000 clergymen from the Anglican Church.

SAVOY DECLARATION, the document uttered by the Independents and Presbyterians who met at the Savoy Hospital in London 29 Sept. 1658. In it these religionists declared the principles of their faith and polity. The Declaration is substantially the same as the Westminster Confession. See CONFESSION OF FAITH, WESTMINSTER.

SAVORY, aromatic herbaceous or half-shrubby plants of the labiate genus *Satureia,* native to the Mediterranean region and the Levant. They are cultivated in kitchen gardens. Summer savory (*S. hortensis*) is an annual with slender branching stems nearly a foot high, bearing soft, lanceolate leaves, often stained with purple, and with lilac or white mint-like flowers in the axils. The young shoots are plucked at flowering time, and dried for flavoring dressings, etc. Winter savory (*S. montana*) is a perennial species, with similar qualities.

SAW-FISH, a ray of the family *Pristidæ,* so called from the sword-like snout, the sides of which are armed with spines, so as to give it the appearance of a large doubled-toothed saw. Armed with this formidable weapon, which may measure two or three feet or more in length, the saw-fish is said to attack even whales, and to inflict severe injuries upon them, while it is certainly destructive to shoals of small fishes upon which the saw-fish subsists. The true teeth of the mouth are small, blunt, and arranged pavement-like. The mouth is situated on the under surface of the head, and the breathing apertures are large and set behind the eyes. The fins, tail and granular scales are shark-like in most respects. About five species are known, all inhabitants of the open ocean, whence they seldom approach the shore; and they perfer warm waters. A common species on the Gulf Coast of the United States is *Pristis pectinatus,* which sometimes enters the lower Mississippi or wanders northward on the Atlantic Coast; it is 10 to 20 feet long. The *Pristisphoridæ,* which bears a similar weapon, are sharks.

SAW-FLIES, insects of the family *Tenthredinidæ,* so called because the ovipositors are constructed of parallel, toothed blades with which the females cut holes in vegetable tissue to receive their eggs. Unlike the wasps, bees, ants and other members of the order *Hymenoptera,* the abdomen is united by its full girth to the thorax; that is, it is sessile. In general they resemble other members of the order in having two pairs of transparent wings with rather few veins and cells, biting mouth-parts, and a complete metamorphosis. The larvæ resemble caterpillars, but have at least six pairs of prolegs instead of five as do the larvæ of lepidopterous insects. They are also frequently slimy, and often they keep part of their bodies curved beneath the edge of the leaf upon which they are feeding. All feed upon living vegetable tissue, and some are troublesome upon cultivated plants. The currant-worm or slug (*Pteronus ribesii*), a yellow bodied European insect, whose black-dotted green larvæ appear shortly after the leaves in spring, eat gluttonously for about three weeks and transform to adults below the ground. Two or three broods may appear in a season. The pear slug (*Eriocampoides lamacina*) is a slimy larva which sometimes

damages pear foliage. Rose slug, grape slug, raspberry slug, turnip fly and willow saw-fly are other well known species which occasionally do damage. In such cases they have been combated with an insecticide (q.v.) which must be eaten, though in some cases dust, forcible spraying with water, and other remedies have been reported effective.

SAW-MILL, a complete sawing machine, with all its adjuncts, for converting logs into planks, boards and slabs. The earliest form was the sawpit with raised trestle horses upon which the log was raised and then sawed by hand saws or by whip saws. Windmill power was applied about the beginning of the 13th century and was soon followed by water power.

All attempts to establish saw-mills in England during the period of 1660–1770 were unsuccessful on account of the opposition of the hand sawyers; but in the United States, beginning with the erection of the mill at Piscataqua Falls in the State of Maine in 1634 a vast number of mills have been built in all of the wooded districts of the country and by the development of improved methods in handling the logs, and in arranging the machinery, have made such States as Maine, Michigan and Wisconsin famous as lumber producing areas.

Of these mills the earlier forms are known as gate or sash saw-mills and consisted of two upright guide posts held in position by a transverse beam at the top. A heavy rectangular wooden frame carrying a straight band saw attached to the top and bottom pieces, worked with a vertical reciprocating motion in slides between the guide posts. The reciprocating motion was imparted to the sliding frame by a connecting rod, the lever end of which extended to one end of a water-wheel shaft. The carriage bearing the log was moved by a rack and pinion arrangement operated by a feed-wheel and the log was fed endwise to the saw, which was run, usually, at a speed of 150 strokes per minute and was capable of producing from 500 to 2,000 superficial feet of lumber per day of 10 hours.

A larger output was obtained by introducing the "gang" feature, which consisted of attaching several saws to the sliding frame. In the "Yankee gang," the saws were arranged in two sets, with the tooth edges of one set facing in a direction opposite to that of the other set, and enabled the sawing of two logs at one movement of the carriage. Other forms, designated "slabbing gang," "stock gang" and "pony gang," applied the method to special purposes.

The "muley" saw followed the gate and gang saws and was adopted generally by the smaller mills on account of the great reduction in the weight of the reciprocating parts. In this arrangement, the ends of the saw are attached to two light cross-heads opposite each other, which oscillate up and down. The saw is kept in line by means of slides working in a strong iron frame swung from an overhead beam. The cutting is accomplished entirely by the downward motion, during which the action of the slides causes the saw-teeth to hug close to the wood and then recede from it during the upward motion, so as to reduce the friction. Muley saws are driven at a speed of about 300 revolutions of the driving wheel per minute and are capable of turning out about 6,000 superficial feet per day.

Saw-mills employing circular saws are of comparatively recent date. The experimental point in the use of the circular saw as the main saw of a mill was passed about the middle of the 19th century, since which time it has been developed to a state of very high efficiency and general usefulness. By its use a continuous cutting motion is obtained and driven by engines ranging from 25 to 100 horse power circular saws in connection with steam feeding arrangements are capable of sawing from 20,000 to 100,000 superficial feet per day, practically limited only by the capacity of the handlers to remove the lumber.

The saw, which is a disc of steel with a toothed edge, is mounted on a shaft which is rotated by gear wheels, or by belts operated by the shaft of a water wheel, steam engine, etc. The cutting depth of the saw is somewhat less than half the diameter of the disc and the saws generally employed rarely exceed a maximum diameter of six feet on account of the increased thickness required to obtain rigidity, and the consequent increase in the amount of the kerf or cut waste. Water power was used almost exclusively until 1835, but it has been almost completely supplanted by steam engines. "Band saws," although known a great many years before the circular saw, were not adopted until recent years on account of the difficulty experienced in making saws of sufficient endurance to withstand the severe service. During recent years, however, these difficulties have been overcome and they are now generally used in all of the great lumber producing countries.

The mechanical arrangement consists of two broad-faced wheels mounted one above the other. Over these wheels, a continuous band of steel, which is the saw, works like a belt over two pulley wheels, with a continuous motion, and the logs are fed endwise against the cutting or toothed edge by a traveling carriage. Mills employing band saws are capable of producing from 40,000 to 80,000 superficial feet of lumber per day and require from 25 to 45 per cent less driving power than mills employing circular saws. The latest thing in band saw-mills is a portable mill in which the log is stationary and the band saw, toothed on both edges, travels in guides lengthwise of the log, dropping the thickness of a board at each traverse and sawing at both the forward and return movements.

Many saw-mills employ both circular and gang saws. Both ordinary blade and band-saws are run in gangs and some band saws run on wheels as large as 10 feet in diameter. The mill is usually built upon the banks of a river or pond. The general construction is quite simple and consists of a saw floor and log deck built at an elevation of about 10 or 12 feet above the water level. A jack ladder constructed of heavy timber with its lower end resting on the bottom of the stream, leads up to the saw floor at the rear end of the mill. Ribbons of iron are fastened to the top sides of the ladder and form the track upon which the log car is operated. The arrangement and installation of the saws vary according to the size of the mills and the kind of work that is done. Since the depth of cut is less than

three feet, usually in mills handling logs of large diameter, increased depth of cut is obtained by mounting two saws one above the other, so that they cut in the same line — the upper one cutting down from the top of the log to the cut of the lower or main saw. In the mills in California, logs measuring up to 10 feet in diameter are sawed by arranging four saws one above the other, some cutting horizontally and others vertically, thus permitting the handling of very large trees.

The gigantic trunks of the redwood trees of California, Washington and other States on the Pacific Coast, ranging from 10 to 25 feet in diameter, are first quartered by explosions of gunpowder and then passed through the mills.

One great disadvantage in the use of circular saws is the excessive kerf waste, which is fully 20 per cent greater than that resulting from the use of the band or the gang saws, and is one of the principal reasons for the employment of the last named forms in the smaller mills where the uniform character of the lumber and the saving of raw material are important factors.

The majority of the American mills use single circular saws, but many of them have saws installed upon each side of the mill floor, and the logs are rolled to either side by the log jack placed in the centre of the building. In addition to these rotaries, the larger mills have from one to four gang saws.

The arrangements for handling the logs which are floated down upon the rivers from the distant forests to the mills, consist of piles driven at convenient distances apart, into the bed of the river adjacent to the mill, to which strong "booms" of logs, are attached by heavy chains and serve to hold the logs as in a pen, until they are required and also to leave a free channel in the middle of the stream. When the mill is in operation, the boomed logs are drawn from the water by an endless chain which runs in a V-shaped log slide and is provided with spikes to prevent the log from slipping back. The logs follow each other in endless succession. When a log reaches the log deck, it is loaded upon the skids by the action of a lever operated by the sawyer, which causes a pair of arms to rise through the mill floor and raise the log forcibly upon the skids. The skids lead to the log carriage, upon the "head blocks" of which the log is securely fastened by the insertion of a "dog," and it is then ready to be advanced to the saw. This is accomplished in several different ways — by rack and pinion worked by "cone feed," consisting of two parallel cones operating a belt which regulates the motion of the pinion shaft; by "rope feed," consisting of a wire rope which passes over pulleys set in the floor to a drum underneath, and is so arranged as to be under the control of the sawyer in the forward movement of feeding, or in the reverse movement of returning the carriage to its original position; or by "steam feed," commonly termed "lightning feed," derived from the force of a steam cylinder about 10 inches in diameter, which is laid upon the mill floor underneath the saw carriage to which the piston is attached. As the log is fed and when the first slab has been removed, the sawyer touches a lever and brings the "nigger," a piece of iron-bound timber with spikes upon its front face, through the floor. The spiked face catches the side of the log and turns it axially at once, to any desired position. If the log is being "canted," or prepared for the gang saw, the slabs are removed from the two opposite sides, a hook is thrown over the rear end of the cant so as to prevent it from returning with the saw carriage, and it is dropped upon a set of rollers which starts it toward the gang. From the time that the log is drawn out of the water and until it emerges from the gang, all of the operations are performed by machinery.

The finished product of saw-mills are beams, planks, boards, etc., of varying sizes in length, breadth and thickness, too numerous to enumerate specifically; laths, consisting of strips four feet in length, three-eighths inch in thickness and one and one-half inches in width, used for lath and plaster work. In 1914, according to the Federal Census of that year, there were 27,229 saw mills operating in the United States. In 1937 the number of establishments reporting lumber and lumber products was 7,647, the number of wage earners 323,928, and the value of products, $848,481,000. The number of active sawmills was over 16,000, and the production 24,354,884 thousand b.f.

For technical description of saws see SAWS AND SAWING; METAL-WORKING MACHINERY, and WOOD-WORKING MACHINERY.

SAW-WHET OWL, a small American owl (*Nyctale acadica*), which takes its name from the rough tone of its cry. It is northerly in its distribution, ranging across the continent, but rarely dwelling as far north as Hudson Bay. It is not so large as a robin and has inconspicuous ear-tufts; bill black; cere tumid; general color: above, chocolate brown, streaked with white; below, white with brown stripes. Its food consists mainly of insects and its nest is made in a hollow of a tree, in an old crow's nest or any convenient place. Compare SPARROW-OWL.

SAWBILL, a motmot (q.v.).

SAWDUST, a general name given the accumulated particles caused by sawing wood, stone, etc. Besides the more common uses of sawdust, it is commercially valuable as the basis of various manufactures. Oxalic acid is manufactured on a large scale from wood sawdust. Sawdust is also used in the "carbonating" stage of the process for the manufacture of soda ash. The sawdust of mahogany and rosewood is used in dressing furs and the small fragments of some woods, such as the pencil cedar, made by saw cuts or the turning tool, yield perfumes. Sawdust sinks in water, though the wood from which it is cut floats.

SAWS AND SAWING. A saw is a tool consisting usually of a thin, flat blade of highly tempered steel serrated or having a series of triangular-shaped teeth usually on one of the edges, but sometimes on both edges. It is one of the most important of the various forms of cutting tools and is extensively used for working wood, metal, stone and other substances, but principally wood.

Saws are made in a great variety of forms and sizes in order to adapt them to the varying characteristics of the material worked and to suit them to the particular kind of work for which they are used and also to suit the circumstances attending the manner in which they are operated or handled.

For illustration of power-driven saws see WOOD-WORKING MACHINERY.

In this article the consideration of the subject will be confined to the construction and adaptation of the various makes of saws for

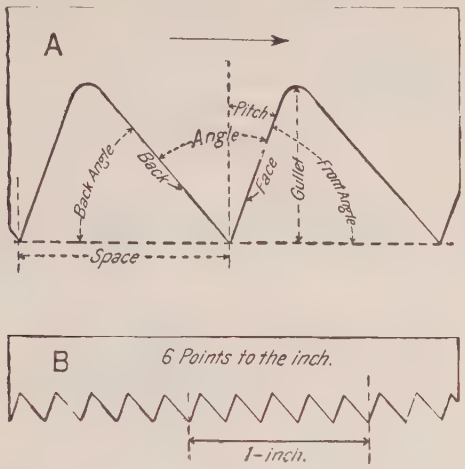

FIG. 1.

specific purposes and to the identification of their generally applied trade names with those purposes.

The characteristic action of the saw being the removal successively of minute portions of the material worked by the cutting or tearing action of a series of sharp edges thrust against the material indicates that it is essentially a tool adapted for cross-cutting or cutting at right angles to the fibre of the material. Necessity and custom, however, have compelled its application for ripping or cutting with the grain also, thus adapting it to work which otherwise would be accomplished by the use of cutting tools such as axes and chisels. These conditions define two primary classes of saws — the cross-cut saws and the rip-saws which divide all the dif-

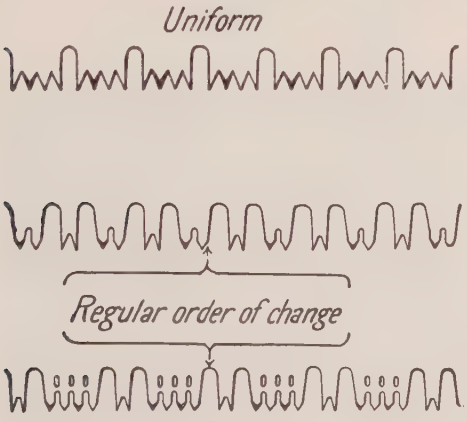

FIG. 2.

ferent kinds of saws into two groups according to the general purposes for which they are used.

Saw Terms.— The principal terms used in describing a saw are as follows: (See Fig. 1, Diag. A).

Space.— The distance between two contiguous teeth, measured from point to point.

Pitch or Rake.— The inclination of the face of a tooth or the angle of the face of a tooth measured from a vertical line drawn through its point.

Gullet.— The depth of the tooth from the point to the root-line, the throat. Also the concave space at the back of a tooth.

Gauge.— The thickness of the blade, usually measured by the wire gauge.

Set.— The amount of lateral inclination

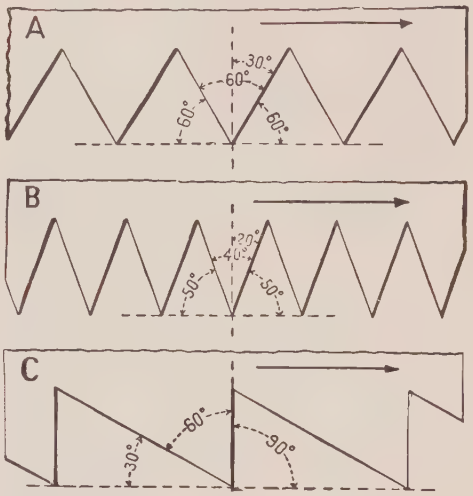

FIG. 3.

given to the teeth, either to the right or to the left of the plane of the blade, in order to produce a kerf or cut of sufficient width to effect a proper clearance of the sawdust and to prevent the saw from binding or being pinched by the sides of the cut.

Fleam.— The side angle of a tooth.

Points.— The number of teeth points to an inch. The coarseness and fineness of saws are usually estimated by the number of points instead of the number of teeth to an inch, and it should be observed that there is always one less tooth per inch than there are points. (See Fig. 1, Diag. B).

The several parts of a saw-tooth are usually described by the following terms: (See Fig. 1, Diag. A).

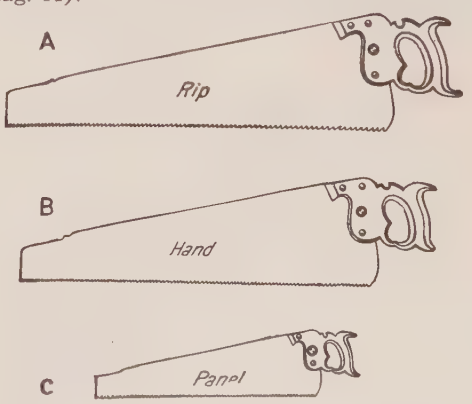

FIG. 4.

Face.— The front or cutting edge of the tooth.

Back — The following or back edge of the tooth.

Point.— The lower end of the V between

saw-teeth; in another sense the outer cutting extremity.

Saw-teeth vary in spacing, length or depth of gullet, angle, pitch, set, fleam and form of

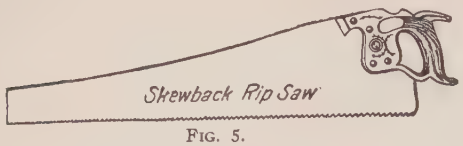

FIG. 5.

gullet. The teeth may be uniform throughout, or the blade may have several different kinds of teeth. In the latter case all the teeth of a kind are made uniform, or they are arranged in a regular order of change. (See Fig. 2).

The "angle" of a saw-tooth is that which is included in its point between the face and the back. The generic angle is 60 degrees, but it varies in the different kinds of teeth from 45 degrees to 70 degrees, according to the character of the material worked and the specific purpose for which the saw is used. The angle suitable for cutting soft wood and for ripping purposes is always more acute than that used for cutting hard wood and for cross-cutting. For soft wood, the front angle varies from 65 degrees to 70 degrees; for hard wood

FIG. 6.

from 80 degrees to 85 degrees. In saws employed for cutting very hard knotty wood, and in those used for cutting metal, the teeth are arranged in a series of equilateral triangles, the pitch of each tooth being evenly divided between the front and the back. In saws used for a general line of work, the angle usually adopted is 40 degrees, with the pitch evenly divided. In saws used for cutting soft woods and for ripping purposes, an effective placing of the angle is attained by making the face upright, and sloping the back. (See Fig. 3, Diags. A, B. C, respectively). The pitch of a saw tooth is obtained by subtracting the back angle from the front angle. These terms and rules apply generally to all the different kinds

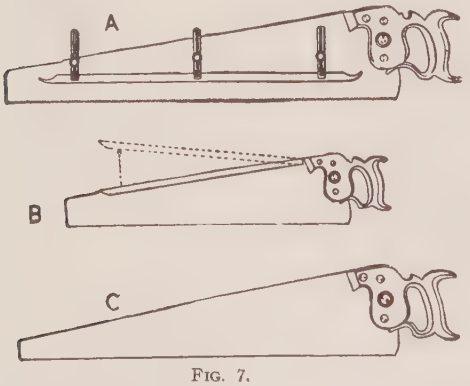

FIG. 7.

of saws from the smallest hand and machine saws used by jewelers, machinists and carpenters, to the largest power-driven saws employed in the various classes of saw mills.

The various kinds of saws manufactured and used at the present time are of the following named general types:

The rip-saw, the hand-saw and the panel-saw. (See Fig. 4).

The carpenter's hand-saw for miscellaneous work is usually made from 20 to 30 inches in length, and is used for the common work of sawing material of moderate thickness both longitudinally and crosswise. The rip-saw and the panel-saw are modifications of the hand-saw, from which they differ in the size of the teeth, and in the length of the blade. The rip-

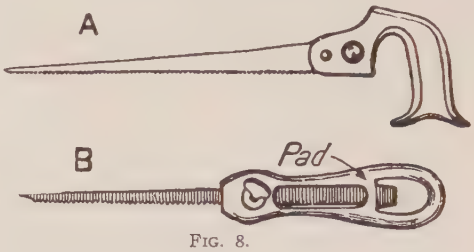

FIG. 8.

saws range from 28 to 36 inches in length, and the panel-saws from 12 to 24 inches. The usual spacing of the teeth of the three types is as follows: Hand-saws, 5 to 12 points per inch; rip-saws, three to five points at the heel or handle end, and six to eight points per inch at the point; and the panel-saws, 8 to 12 points to the inch. All three forms are made with a straight upper edge, or a "skewback" curve as shown in Fig. 5. A novel and useful form is represented by the "combination" saws. These are graduated along the upper edge, and sometimes furnished with a level attachment as

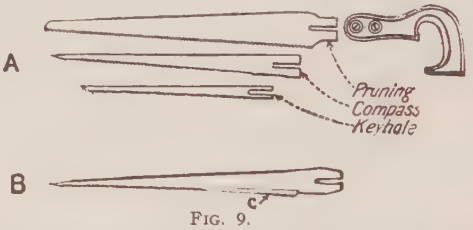

FIG. 9.

shown in Diag. A, Fig. 7. Other useful modifications of the hand-saw are the gauge-saw, the ship-carpenter's saw, and the movable-back saw, shown by Diags. A, B, C, respectively, of Fig. 7. The gauge-saw is equipped with a movable attachment by means of which it may be adapted to tenoning, shouldering, curving, cog-cutting or to any other purpose where a definite depth of cut is required. The movable-back saw combines the advantages of a thin-bladed hand-saw and a first class back-saw. The ship-carpenter's saw has a very long narrow blade and is especially suitable for cutting sweeps or curves of long radius. It is handled like the rip-saw, and is extensively used by cabinet-makers, pattern-makers and others for work requiring a narrow saw.

The compass-saw and its modifications, the various form of keyhole-saw, which are also commonly known as pad-saws and socket-saws, are shown in Fig. 8, Diags. A and B, respectively. The blades of the compass-saws range from 10 to 20 inches in length, and taper from one-eighth inch at the point to two or more inches at the heel. They are used for cutting

curves and sweeps by hand and are sometimes called table-saws. The regular keyhole-saw and its modification, the pad-saw, are simply smaller forms of compass-saws, and are used for cutting curves of small radius, such as keyholes and other small holes in the central

Fig. 10.

portions of work. A saw of this type consists of a narrow blade which slides into a hollow handle or pad, to which it is secured in place by one or more set screws, only so much of the blade being drawn out as may be required by the character of the work. These saws are made both simply and in "nests." A nest of

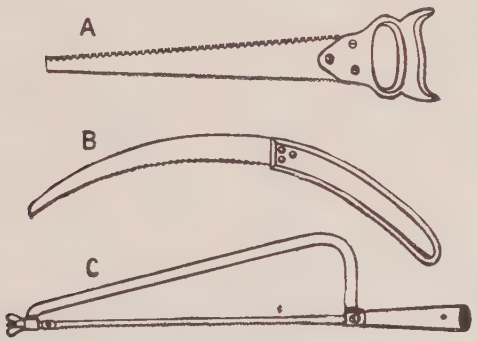

Fig. 11.

saws consists of a handle and three interchangeable blades, one each of the keyhole or pad, the compass and the table or pruning-saws. (See Fig. 9, Diag. A). A very useful novelty in this line is the nest of saws designed for cutting square holes. In this combination, the keyhole and compass blades are fitted with an attach-

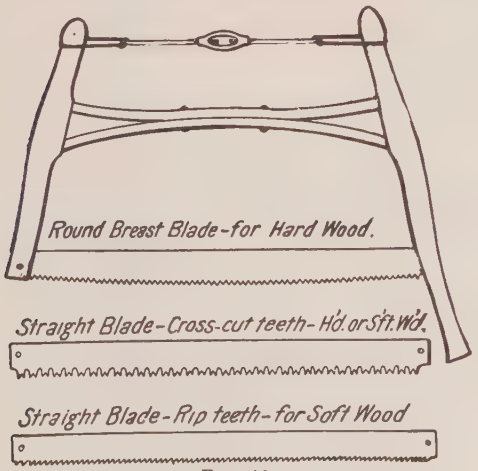

Fig. 12.

ment at right angles to the plane of the blade as shown at (C) Diag. B, Fig. 9.

The back-saws are a class of hand-saws characterized by deep thin blades stiffened with a metallic back as shown in Fig. 10. The principal forms are the mitre-box saw, the tenon-saw, the sash-saw and the dovetail-saw. The last named has the thinnest blade, so thin that simple filing gives the teeth sufficient set. The blades of the others are somewhat thicker and require a slight amount of set. All back-saws are best used in a mitre box or in some other form of guide rest. In cutting, they should be held firmly with the least practicable expenditure of force in controlling their direction, and the cut should be commenced by placing the heel of the blade on the farthest edge of the work and then drawing the saw steadily toward the body of the operator. Back-saw blades range from 8 to 18 inches in length,

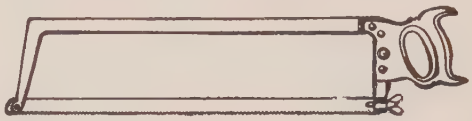

Fig. 13.

the number of teeth varying in number from 10 to 14 per inch.

The pruning-saws are of several kinds, the principal forms of which are shown in Fig. 11. They vary from a large form of compass saw to straight saws toothed on both edges as shown in Diag. A, and also to those with curved blades as shown in Diag. B, a form extensively used on the Pacific Coast. They are also made of narrow blades attached to metal frames, the shape of which produce a tapered combination which permits of the use of the saw in very narrow spaces. See Fig. 11, Diag. C.

The construction of the tapered pruning-saw places it on the dividing line between what may be termed the regular bladed saw and the frame saw. In the former, the pressure on the cutting edge is resisted by the rigidity of the blade itself, while in the latter the pressure is resisted by the distribution of the tension of the blade through the various parts of the frame. Of the frame saws, the most familiar are the wood-saws shown in Fig. 12, the butchers' saws shown in Fig. 13 and the hack-saws shown in Fig. 14. The last named is shown in its adjustable and extendable form, in which the frame may be lengthened or shortened to fit blades of varying length. The saw has a thin, narrow blade and equilateral triangular-shaped teeth. It is stretched between the upright portions of a wrought-iron or steel frame, the

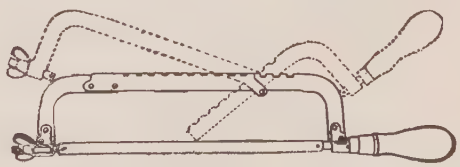

Fig. 14.

requisite tension being imparted by means of a thumb-screw at the forward end. A handle is attached to the back end of the frame, which is usually grasped by the right hand of the operator, and the downward pressure imparted to the tool during the act of cutting by laying the left hand upon the back or top of the frame. This saw is extensively used by fitters and mechanics for cutting odds and ends of metal, and has now become one of the most important tools in a machinist's toolbox. For general work, the blades are made with 14 teeth to the inch, but those used for cutting tubing and thin metal are

usually made with a greater number of teeth, about 25 per inch, in order to prevent a free bite and to reduce the danger of stripping the teeth. As in the case of the file, the fineness of the bite depends upon the number of the teeth in contact with the work; therefore, the judgment of the operator usually determines the amount of pressure that should be applied to the saw to suit the varying conditions of the cut. As in the case of other cutting tools, experience teaches that a hack-saw will work more effectively under a pressure sufficient to make the tool bite freely, than when it is allowed to scrape and glaze the surface under a light pressure. In order to use a hack-saw properly, the blade should be strained in the frame to prevent its kinking, and the cutting strokes should be made uniformly at a rate not exceeding 40 per minute. The blades should

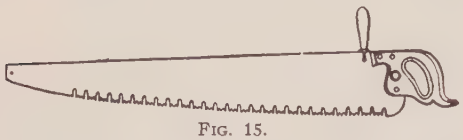

FIG. 15.

be as short as possible, so as to reduce the cost and the danger of breakage, and oil should *never* be used on the teeth as it decreases their cutting efficiency. The reverse is true in the case of wood-working saws. Hack-saw blades as regularly manufactured range from 6 to 18 inches in length. Those longer than eight inches for hand-saws and 12 inches for power-driven saws are seldom required. The rail-saw is a modification of the hack-saw, the height of the frame being increased to adapt it for large work, such as the cutting off of rails, large beams, girders, etc., and is found to be a very valuable tool for contractors. The frames are fitted to carry blades ranging from 9 to 18 inches in length.

The cross-cut saws employed for cutting timber and other large work are made in an almost innumerable variety of forms and sizes both as to the blades and to the teeth. The "one man" saws, shown in Fig. 15, range from three to six feet in length. The particular saw illustrated has the famous "Great American" tooth, commonly known as the M tooth. Fig. 16 shows three forms of the larger saws. They range from 4 to 10 feet in length and are operated by two men, one at each handle. They are made with either curved or straight backs, but are always round-breasted, and differ in this respect from the drag- and pit-saws, in which the toothed edge is always straight.

Other saw terms are defined as follows: Arbor, the shaft, spindle or mandrel of a circular saw; crown-saw, the end of a cylinder having saw teeth arranged to cut out a round hole, called also a cylinder- or drum-saw; jump-saw, a circular saw made adjustable in up-and-down position; razor-saw, a hardened steel toothless wheel made thin for cutting stone, etc.; ring-saw, a band-saw set on guides to operate in a ring or circle; saw-back, the stiffening piece on the back of a band-saw; saw-bench, a bench fitted with guides, gauges, stops, clamps, fences, etc., for supporting and guiding work to be sawed; saw-gate, a frame in which gang-saws are set to stiffen them and prevent buckling, a similar device is termed a saw-hanging; saw-jointer, a mechanism for holding in position the blades of gang-saws while they are filed and set; saw-jumper, a device for spreading or setting saw-teeth; saw-table, the level surface on which the work is fed to a circular or band-saw that cuts through a gap in the table; saw-wrest, levered device for straining a saw-blade in giving the teeth a spring-set. The saw industry of the United States is mainly confined to about 80 factories, having 4,384 employees. In 1937 these produced a gross value of $19,853,034, but more than a third of this was the value of the steel and other materials used. The industry more than doubled its production between 1914 and 1925. Illinois is

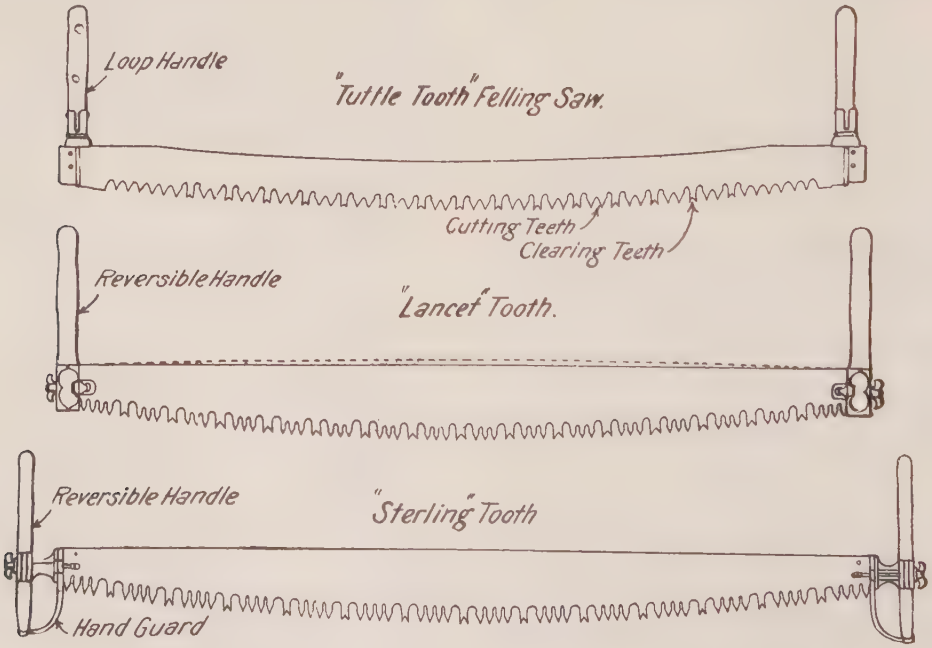

FIG. 16.

the leading state, followed by New York. See also Wood-Working Machinery; Lumber Industry in the United States.

SAWYER, Charles, American public official: b. Cincinnati, Ohio, Feb. 10, 1887. He obtained degrees from Oberlin College in 1908, and from Cincinnati University in 1911. After serving in the army in World War I, he practiced law in Cincinnati and entered politics. He was lieutenant governor of Ohio in 1933–1934, and from 1936 to 1944 was a member of the Democratic National Committee. In 1944–1945 he served as ambassador to Belgium and minister to Luxembourg. On May 6, 1948, he became secretary of commerce. On resigning in 1953 he returned to his law practice in Cincinnati, and became a director of the Kennecott Copper Corporation.

SAWYER, Leicester Ambrose, American clergyman and Biblical scholar: b. Pinckney, N. Y., July 28, 1807; d. Whitesboro, N. Y., Dec. 29, 1898. He was educated at Hamilton College, studied at Princeton Theological Seminary, and in 1832 entered the Presbyterian ministry. He became president of Central College, Ohio. In 1854 he withdrew from the Presbyterian denomination and joined the Congregationalists. He made a complete translation of the Bible, published between 1858 and 1891.

SAWYER, Philip, American architect: b. New London, 1868; d. New York, May 21, 1949. After serving with the United States Geological Survey, he studied architecture at Columbia University, the Beaux Arts in Paris, and in the office of McKim, Mead and White. He formed the firm of York and Sawyer, in New York. Among the important buildings designed by him are the federal buildings at Honolulu, the Children's Village at Dobb's Ferry, the New York Historical Society Building, the Federal Reserve Bank of New York, the First National Bank of Boston, and buildings for Vassar, Smith, Rutgers and other colleges. He served as consulting architect for the Board of Water Supply of New York, and for the departments of Commerce and Labor.

SAWYER, Sylvanus, American inventor: b. Templeton, Mass., April 15, 1822; d. Fitchburg, Mass., Oct. 13, 1895. His attention was early turned to invention, and in 1839 he engaged in business with his brother-in-law in Augusta, Me., and invented a steam engine, a screw propeller and a car run by foot power. His first big invention, however, was the machine for making chair cane from rattan, invented in 1843 and used in his factories after 1850. Sawyer then turned his attention to gun and rifle projectiles and made important inventions, his projectiles making the rifled cannon a practicality. In 1853 he invented an arrangement by which shells would explode on impact, by use of percussion caps. These inventions were put into use and did great service against the Confederacy in the Civil War. Other inventions, after the war, perfected the cast-steel rifled guns, the first battery of which he furnished. His other inventions include calipers and dividers, a steam generator, a sole sewing machine, and a centering watchmaker's lathe.

SAWYER, Thomas Jefferson, American Universalist clergyman: b. Reading, Vt., Jan. 9, 1804; d. Medford, Mass., July 24, 1899. He was graduated at Middlebury College in 1829, and held pastorates in New York (1830–1845 and 1852–1861). Between these periods he served as principal of the Liberal Institute of Clinton, N. Y., in which he also taught theology. He was one of the founders of Tufts College, Medford, Mass., where he became professor of theology. As an advocate of Universalist doctrine and as a scholarly controversialist he acquired a wide reputation. His discussion with Isaac Westcott was published under the title of *The Doctrine of Eternal Salvation* (1854).

SAXE, Comte (Hermann) Maurice de, marshal of France: b. Dresden, Oct. 28, 1696; d. Chambord, near Blois, France, Nov. 30, 1750. He was a natural son of Augustus II, elector of Saxony and king of Poland. His military career was begun at the age of 12, and a few years later he was put in command of a cavalry regiment which took part in the war with Sweden. After the Treaty of Utrecht he attached himself to the French Army and in 1720 was made camp marshal to the duke of Orléans. He was offered the command of the Saxon Army at the death of his father but chose to remain in the French service. For his defense of Alsace in 1743 he was created marshal of France. Thomas Carlyle has described his heroic conduct in the Battle of Fontenoy, in his life of Frederick the Great. He was one of the most fearless but also one of the most dissolute men of his day. He wrote with a singular disregard of the rules of orthography a book on the art of war, entitled, *Mes Rêveries* (1891–1893).

SAXE, săks, **John Godfrey,** American poet: b. Highgate, Vt., June 2, 1816; d. Albany, N. Y., March 31, 1887. He was graduated at Middlebury College and admitted to the bar in 1843. During 1850–1856 he conducted the *Sentinel* at Burlington, Vt., and in 1856 became attorney general of Vermont and deputy collector of customs. He moved to Albany, N. Y., where he edited the *Evening Journal.* He was a conspicuous figure on the lecture platform and at scholastic anniversaries, where he often read his verse. His reputation as a humorous poet was considerable during the mid-century, his verses often appearing in *Harper's Magazine* and in the *Knickerbocker.* He published several volumes of light verse, including *Progress, a Satirical Poem* (1846); *Fables and Legends of Many Countries* (1872); and *Leisure Day Rhymes* (1875).

SAXE-ALTENBURG, SAXE-COBURG, SAXE-MEININGEN, and **SAXE-WEIMAR,** săks-äl′tĕn-bo͝orĸ, -kō′bûrg, -mī′nĭng-ĕn, -vī′mär, former German duchies of Thuringia. From the 13th century these territories had belonged to the margraves of Meissen, who in the person of Frederick I the Warlike, a member of the Wettin family, became electors of Saxony as well. In 1485 the Wettin family divided its possessions. The elder brother Ernest received the Wittenberg lands, on which the electoral dignity rested, and Thuringia; Albert was given the margravate Meissen with Dresden and Leipzig. (See Saxony, German electorate and kingdom.) The protection of Luther and the cause of the Reformation brought the Ernestine line into conflict with Emperor Charles V, who, supported by Duke

Maurice of Saxony, defeated and captured Elector John Frederick in 1547. The Wittenberg lands and the electoral dignity were given to Maurice and remained thereafter with the Albertine line. John Frederick, assuming the title of a duke of Saxony, was confined to the rule of Thuringian territories. Since no laws of primogeniture were established until late in the 18th century, these territories experienced a series of partitions, reunions, and redivisions, which reached an end only on May 1, 1920, when most of the Saxe territories and the principalities of Reuss and Schwarzburg formed the state of Thuringia within the German Empire. In 1945 this state became part of the Soviet occupation zone, but ceased to exist as such when all states in the German Democratic Republic were dissolved in 1952.

The division of the Thuringian lands began after the death (1554) of Duke John Frederick who had taken his seat in Weimar and had founded the University of Jena as a center of orthodox Lutheranism. In 1554 his four sons partitioned the duchy into the four duchies of Weimar, Gotha, Coburg, and Altenburg. One of the sons of Duke John of Weimar was the renowned general of the Thirty Years' War, Bernhard of Weimar (1604–1639). With the expiration of the lines of Coburg, Gotha, and Eisenach by 1640, their lands came to the sons of Duke John. Ernest I the Pious, of Gotha-Coburg, also inherited Altenburg in 1672, but his possessions were divided after his death in 1675 among his seven sons. William, an elder brother of Ernest the Pious, ruled Weimar and Eisenach, which his heirs split into Saxe-Weimar, Saxe-Jena, and Saxe-Eisenach. But in 1741 a reunion took place under Duke Ernest Augustus I of Weimar, who finally bound his succession by a law of primogeniture. The duchy (from 1815 a grand duchy) of Saxe-Weimar-Eisenach retained its territorial identity thereafter. It received some small additional territories at the Congress of Vienna.

Saxe-Coburg passed after the death of Ernest the Pious of Gotha-Coburg to his son Albert and in 1699 to Albert's younger brother Duke John Ernest of Saxe-Saalfeld whose descendants retained Coburg until 1918 and Saalfeld until 1826. A redivision of territories belonging to the branch of the Ernestine line, begun with Ernest the Pious, took place in the latter year. Frederick I, eldest son of Ernest the Pious, had received in 1679 Gotha and Altenburg, which remained under the rule of his descendants to the expiration of the line in 1825. Ernest III of Saxe-Coburg-Saalfeld gave Saalfeld to Saxe-Meiningen and received Gotha, thereupon calling himself Duke Ernest I of Saxe-Coburg-Gotha. His brother Leopold in 1831 became king of the Belgians, and his younger son Albert became consort of Queen Victoria of England. After the death of his son Ernest II in 1893, a son of Queen Victoria, Alfred, duke of Edinburgh, assumed the government, followed in 1900 by his nephew Charles Edward, who abdicated in November 1918. When Gotha joined the new state of Thuringia, Coburg went to Bavaria.

In 1826 the ruler of Saxe-Hildburghausen, a duchy which had also existed since 1679, ceded his territory to Saxe-Meiningen and became duke of Saxe-Altenburg, the easternmost of the Saxon duchies located in the hills and valleys of the Saale and Pleisse rivers, while Saxe-Meiningen was farthest to the west along the Werra River. Of the four Saxon duchies existing after 1826—Saxe-Weimar-Eisenach, Saxe-Coburg-Gotha, Saxe-Altenburg, Saxe-Meiningen—all but the last sided with Prussia in the struggle for German unification. Saxe-Meiningen joined Austria in the war of 1866 and was occupied by Prussian troops. Its Duke Bernhard was forced to abdicate in favor of his son George II who, with all the other Saxon dukes, joined the North German Confederation and subsequently the German Empire.

The largest and most important of all the duchies was Saxe-Weimar-Eisenach. From 1741 it consisted chiefly of two major sections: the region around Eisenach at the northwestern tip of the Thuringian Mountains, and the Weimar-Jena territory covering the north-central slope of these mountains. The duchy became world famous when in the second half of the 18th century its ruler, Duke Charles Augustus (r. 1758–1828), brought to its capital city, Weimar, and to the University of Jena the leading spirits of the great German civilization of the age. Christopher Martin Wieland, Johann Gottfried von Herder, Friedrich von Schiller, and Johann Wolfgang von Goethe spent their best years in Weimar, while the University of Jena attracted, apart from Schiller, philosophers of the rank of Friedrich W. G. von Schelling, Georg W. F. Hegel, Johann Gottlieb Fichte, and Jakob Friedrich Fries. In 1816 Grand Duke Charles Augustus was one of the first German princes to give his country a constitution and grant complete freedom from censorship. It was from Saxe-Weimar-Eisenach that the national movement of German students, the German *Burschenschaft,* took its origins. Weimar also remained under Charles Augustus' successors a center of German arts. It was often referred to as the capital of German culture in contrast to Potsdam as the capital of Prussian-German power politics. Such considerations contributed to the choice of Weimar as meeting place of the German Constituent Assembly in 1919, which drafted the constitution of the first German republic.

HAJO HOLBORN,
Professor of History, Yale University.

SAXIFRAGE, săk'sĭ-frĭj, a plant of the *Saxifraga* genus of the family Saxifragaceae, the name arising from an old Roman notion that the plants, which they often saw growing in cracks in rocks, had split the rocks themselves, and applying the doctrine of signatures, they concluded that the saxifrage would also break up stones in the bladder. The many species of saxifrage are found chiefly in the north temperate and Arctic zones, increasing in number northwards; they are also characteristic of sub-Alpine and Alpine floras. This northern and mountain habit has made them

Saxifrage: *Saxifraga oppositifolia.*

valuable for rock gardening, especially as the Alpine species have comparatively large flowers. The species are easily propagated by stolons and offshoots. Saxifrages are closely allied to the Rosaceae, and have numerous regular flowers, mostly in corymbs or panicles, and white, yellow, purple or pink in color. The individual flowers are generally small, five-parted, with a two-celled ovary, becoming a small two-beaked pod with many seeds.

The London pride (*Saxifraga umbrosa*) is much cultivated in European gardens, and sends up from a rosette of thick glabrous leaves small pink and white flowers panicled on a stem nearly a foot high. The purple saxifrage (*S. oppositifolia*) is one of most widely distributed species of Alpine and Arctic floras, and one of the first to bloom. It extends as far southward in the United States as Vermont, and carpets the rocks with its evergreen mats of thick foliage, nearly covered with solitary lilac blossoms. The most familiar saxifrages in eastern America are *S. virginiensis* and *S. pennsylvanica*. The former is one of the first spring plants to bloom. It grows in rock crevices and begins to open its small white flowers, while they are still close to the rosette of spatulate leaves. As the spring advances, the naked, pubescent flower scape elongates until, in fruit, it is perhaps a foot high and branched in a loose panicle. *S. pennsylvanica* is a little later in blooming, larger, and frequents swamps and wet banks; it has greenish white, purple, or rarely white flowers in panicles, and oval to oblanceolate leaves.

SAXO GRAMMATICUS, săk'sō gră-măt'ĭ-kŭs, Danish historian: b. about 1150; d. Roeskilde, Denmark, ?1220. He was a native of Denmark, of which kingdom and its dependencies he compiled history down to 1186 under the auspices of Archbishop Absalon of Lund, whose secretary he appears to have been. This work, *Historia Danica* or *Gesta Danorum,* is written in good correct Latin, which Erasmus praised, and occupied 20 years in its composition. Saxo chose as his models the later Roman historians, especially Valerius Maximus, yet in some of his expressions and in his mode of representation he is quite medieval. The work is divided into 16 books, the earlier of which give a highly colored and imaginative account of ancient Danish history as learned from tales and traditions and is full of living pictures of old heroic wars and adventures; the first nine books can scarcely be looked upon as reliable history, but when the writer approaches his own time his history is of the greatest value.

SAXONS, săk'sŭnz (Ger. SACHSEN), name of a Teutonic tribe first mentioned in history by the geographer Ptolemy in the 2d century A.D. They were settled in the southern part of the Cimbrician Peninsula, supposedly present-day Schleswig. From here they advanced during the 3d and 4th centuries beyond the Elbe and Weser rivers. Some of the Saxons, together with the Angles, after a long period of marauding raids, migrated in the 5th and 6th centuries to England. (See ANGLO-SAXON.) The remaining Old Saxons, as those on the Continent were called, expanded in the meantime throughout a considerable part of northwestern Germany. The Elbe and Saale rivers were the boundaries of their eastward extension, in the south they bordered on the Hessians and Franks, and in the west the Rhine north of the Lippe formed the border. Only along the coast of the North Sea the Friesians maintained themselves as a separate tribe.

The Saxons were composed of four major groups: Westphalians, Angrarians (Engerns), Eastphalians, and (in Holstein) Nordalbingians. They conducted continuous warfare with the Franks. After a long series of bloody wars (772–804), Charlemagne subjugated and forced them to accept the Christian religion. Bishoprics were founded in Bremen, Verden, Minden, Münster, Paderborn, and Osnabrück, subsequently also in Hildesheim and Halberstadt. The Saxons continued to live under their own laws which Charlemagne had collected and which formed a corpus called the *Lex Saxonum.*

HAJO HOLBORN.

SAXONY, săk's'n-ĭ (Ger. SACHSEN, zäk'sĕn), early German duchy in the northwestern area of Germany, inhabited in the 3d century A.D. by the Germanic Saxons (q.v.). With the dissolution of Charlemagne's empire in the 9th century, there emerged the tribal duchy of Saxony which combined the low-German territories between the Rhine and the Elbe rivers. Saxony was one of five German tribal or "stem" duchies into which the East Frankish Empire tended to dissolve. Otto, son of a Saxon noble named Liudolf, was named the first duke of Saxony (r. 880–912), and in 908 acquired Thuringia also. His son Henry the Fowler (r. 912–936) was elected German king (Henry I) in 919, thus establishing the line of Saxon Holy Roman emperors: Otto I (r. 936–973), Otto II (r. 973–983), Otto III (r. 983–1002), and Henry II (r. 1002–1024).

In 960 Otto I gave the duchy to a relative, Hermann Billung, who extended it eastward, though his authority was largely restricted to the northern parts. After the expiration of the Billung dynasty in 1106, Count Lothair of Supplinburg became duke of Saxony. After becoming emperor (Lothair II) in 1125, he gave the duchy to his son-in-law, Henry the Proud, duke of Bavaria, a member of the Guelph family. But in 1138, Emperor Conrad III took the duchy from Henry and bestowed it on the Ascanian margrave of Brandenburg, Albert the Bear. Henry the Lion, son of Henry the Proud, refused to acknowledge the Ascanian claim and in 1142 was again granted the duchy. He extended the Saxon power as far as the Oder and the Baltic Sea. But simultaneously he became the most powerful opponent of the universal aspirations of the Hohenstaufen or Ghibelline emperors. (See GUELPHS, OR GUELFS, AND GHIBELLINES.) His struggle with Emperor Frederick I resulted, in 1180, in the loss of all his fiefs.

Saxony was divided: Cologne received the duchy of Westphalia; other territories went to the archbishops of Bremen and Magdeburg and the bishops of Osnabrück, Paderborn, Minden, Hildesheim and Halberstadt. The counts of Oldenburg, Lippe, and Holstein were made imperial princes. The Guelph dynasty retained only the lands of Brunswick and Lüneburg, in the center of the old tribal duchy of Saxony, popularly called Lower Saxony. In subsequent centuries, Brunswick-Lüneburg emerged as the most important state, its rulers becoming electors of Hannover in 1692. Only in 1946 were the major parts of the old Saxon duchy united again in the State of Lower Saxony (Niedersachsen), one of the nine states forming the Federal German Republic.

The Ascanians received Lauenburg and the country around Wittenberg on the Elbe, which were the only parts of the former duchy which retained the name Saxony and the ducal title. The Golden Bull of 1356 raised Saxony-Wittenberg to an electorate of the empire. Upon the expiration of the Ascanian line of Saxony-Wittenberg, Emperor Sigismund gave the electorate in 1423 to Frederick I the Warlike, a member of the Wettin family. As margrave of Meissen and landgrave of Thuringia, Frederick ruled the lands to the south. (See also SAXONY, electorate and kingdom.)

HAJO HOLBORN.

SAXONY, German electorate and kingdom. The main part of the state of the Wettin dynasty was the march or mark Meissen (Misnia), the land north of Bohemia, west of Silesia, east of Thuringia, and south of the old Saxony and Brandenburg. In the 13th century the margraves of Meissen became landgraves of Thuringia as well. Frederick I the Warlike, who founded the University of Leipzig in 1409, acquired in 1423 the duchy of Saxony-Wittenberg which gave him the rank of elector. Soon the name Saxony was applied also to the region formerly called Meissen. His grandsons, Ernest and Albert, divided the territories between them in the Leipzig partition of 1485. Ernest received most of Thuringia, Saxony-Wittenberg, and the electoral title, while Albert as duke of Saxony ruled Meissen and northern Thuringia. Elector Frederick III the Wise (r. 1486–1525) founded in 1502 the University of Wittenberg, from which in 1517 Luther's reformation started. Frederick and his successors, John the Constant (r. 1525–1532) and John Frederick (r. 1532–1547), protected Luther's precepts against the decrees of the church and Emperor Charles V. The emperor defeated and captured John Frederick in the Schmalkaldic War of 1546–1547. The Ernestine line of the house Wettin lost Wittenberg and the electoral title; both went to Duke Maurice of the Albertine line who was an ally of Charles V, though in 1552 he led the rebellion of German princes which blocked the plans of religious and imperial restoration forever. The Ernestines remained confined to Thuringia. In the absence of strict laws of primogeniture they divided their territories into a number of duchies of which (apart from the largest, Saxe-Weimar) Saxe-Altenburg, Saxe-Coburg, and Saxe-Meiningen were historically significant. (See SAXE-ALTENBURG, SAXE-COBURG, SAXE-MEININGEN, AND SAXE-WEIMAR.)

The historical role of Saxony in the 16th century was to a large extent made possible by the advanced economic development of the region. It was then one of the chief mining regions of the world (silver, copper, precious stones, tin, and salt) and a center of textile industries. Under Elector Augustus (r. 1553–1586), Saxony received an excellent administration from which Leipzig especially profited in its rise as the great emporium of central Germany.

During the Thirty Years' War, Saxony fought first with Gustavus Adolphus of Sweden against the German emperor, Ferdinand II, but in 1635 concluded the Treaty of Prague, and as a consequence suffered much devastation by Protestant armies in the years thereafter. After 1648 the rise of absolutism proved irresistible. At the same time the court developed great luxury which reached its height under Frederick Augustus I (known as Augustus the Strong, r. 1694–1733), who made Dresden one of the most beautiful baroque cities on the Continent. (The architectural monuments of that epoch were mostly destroyed by air attacks in the last days of World War II.) Augustus the Strong, after joining the Roman Catholic Church, also became king of Poland in 1697. Saxony lost thereby the leadership of the Protestant princes of northern Germany, which honor fell to the rising Brandenburg-Prussia. The Polish ambitions forced Saxony to side with Austria and she suffered severely in the wars of Frederick II of Prussia (r. 1740–1786), whose highest, though unfulfilled, ambition was the conquest of Saxony.

In the Napoleonic Wars, Elector Frederick Augustus III (r. 1768–1806) joined France after the defeat of Prussia in 1806–1807. Enriched by Prussian territory and raised to king of Saxony as Frederick Augustus I the Just (r. 1806–1827) he became a member of the Confederation of the Rhine (q.v.). Napoleon also gave the crown of the Grand Duchy of Warsaw to the new Saxon king in 1807. In the Battle of Leipzig (1813), King Frederick Augustus I was captured, but at the Congress of Vienna (1815), Prince von Metternich saved the existence of the kingdom of Saxony, which Prussia wanted to annex. Saxony was compelled, however, to cede to Prussia about one third of her territories, among them the region of Wittenberg which in the 15th century had given her the name Saxony. (See SAXONY, province of Prussia.)

Saxony became in 1815 a member of the German Confederation and joined in 1833 the Prussian Customs Union (Zollverein). In 1831 the country received a constitution. During the German revolution of 1848–1849 the liberal and democratic movements showed great strength but were defeated. Count Otto von Bismarck's policy was opposed by the Saxon government of Count Friedrich von Beust, but Saxony was beaten by the Prussian Army on the battlefields of Bohemia in 1866. Bismarck accepted Saxony as a member of the North German Confederation of 1867 and of the German Empire of 1871.

The collapse of the empire and the revolution of November 1918 forced the abdication of the last king, Frederick August III, and Saxony became a state within the Weimar Republic. When Hitler abolished all state rights in Germany in 1933, Saxony came under the control of a Nazi governor, Martin Mutschmann. After 1945, Saxony became one of the five states (*Länder*) of the Soviet occupation zone and in 1949 of the German Democratic Republic. In 1952 the Communists abolished the states.

Saxony from 1815–1952 covered an area of 9,366 square miles which made it the fifth largest state within the German Empire. It was formed like a rectangular triangle. Its southern frontier toward Bohemia ran along the ridges of the Erzgebirge, the Elbsandsteingebirge, and Lusatian Mountains. Most of Saxony is mountainous and hilly; only the northern sections around Leipzig and Meissen are part of the North German plain. Since the late Middle Ages it has been the most densely populated area in Germany and remains so today, except for the smaller Ruhr district in western Germany. In the German Empire, Saxony was the third largest state in population (1871: 2,556,000; 1933: 5,200,000).

Saxony's modern industrialization in the sec-

ond half of the 19th century made it the most industrialized state of Germany. Its industries were, however, chiefly manufacturing. There is some hard coal in the Zwickau region, as well as small iron mining. More important is brown coal (lignite) mining, chiefly around Leipzig. The overwhelming group of Saxon industries comprise textile, machine, metalware, electrical equipment, optical and glass, clock, paper, and furniture manufactures. To these may be added some specialized branches such as the world-famous porcelain works of Meissen and the printing trade of Leipzig, the greatest center of German book production in the 18th and 19th centuries. Leipzig was not only the largest industrial city of Saxony but also one of the greatest commercial centers on the Continent.

Other important cities are Dresden, Chemnitz, Meerane, Plauen, Reichenbach, Zwickau, Zittau, Freiberg, and Kamenz. In 1946 the Russians began to mine uranium in the Erzgebirge. The enterprise is directed by the Soviet-owned Wismut Aktien Gesellschaft with headquarters near Chemnitz. The corporation was supposed to have employed in 1951 as many as 225,000 workers, most of them forced labor.

HAJO HOLBORN.

SAXONY, province, Prussia, Germany. Under the terms of the Vienna peace settlement of 1815, the king of Saxony ceded a third of his lands to Prussia (see SAXONY, German electorate and kingdom). Most of them, including Wittenberg and the region along the middle Elbe, as well as northern Thuringia were brought together with former Prussian territories between the Elbe and Harz Mountains and formed after 1816 the Prussian Province of Saxony. Magdeburg became the capital of the new province, which consisted of three governmental districts (Magdeburg, Merseburg, and Erfurt) and 52 counties, covering altogether an area of 15,955 square miles. The population of the province passed the two million mark by 1871 and reached 3,400,592 in 1933 (3 million Protestants, 251,000 Roman Catholics). The province contained in the north some of the best agricultural areas of Germany on which was also based an important sugar industry. Around the Harz, remnants of the medieval mining of copper, lead, silver, and sulphur survived. The most important resources were the large lignite deposits and salt mines around Halle and Bitterfeld. They favored the development of large chemical industries. By 1933 one fifth of Germany's big chemical production was located in the Prussian Province of Saxony. In the war economy of the Nazis many of the factories of synthetic materials were erected in the province. The great lignite deposits served as the chief source of electric power. In 1945 the Province of Saxony became part of the Soviet occupation zone. By adding the small state of Anhalt, the Russians formed, in 1945, the state of Saxony-Anhalt (q.v.). In July 1952 all states in the Soviet zone were abolished and replaced by smaller administrative units.

HAJO HOLBORN.

SAXONY, Orders and Decorations of. See ORDERS AND DECORATIONS—*Germany.*

SAXONY-ANHALT, ăn'hält, former state, Germany, organized by the Soviet military government in 1946 as one of the five states (Saxony-Anhalt, Saxony, Thuringia, Brandenburg, Mecklenburg) within the Soviet occupation zone; area 9,525 square miles. It was composed of the small former State of Anhalt and most of the Prussian Province of Saxony, which was formed in 1815 by joining the territories then ceded by Saxony to the Altmark and Magdeburg. Halle became the capital of Saxony-Anhalt. In 1952 all five states within the German Democratic Republic were abolished and superseded by 14 governmental districts.

SAXOPHONE, săk'sō-fōn, the name of a group of musical instruments invented by Antoine Joseph Sax, better known as Adolphe Sax. They consist of a conical brass tube, sounded by a mouthpiece furnished with a single reed similar to that of the clarinet. They have 18 to 21 noteholes of graduated size controlled by keys for the first three fingers of the right hand, and are all fingered alike.

SAXTON, Joseph, American inventor: b. Huntingdon, Pa., March 22, 1799; d. Washington, D.C., Oct. 26, 1873. After a two-year apprenticeship to a watchmaker he went in 1817 to Philadelphia where he worked at his trade 11 years, studying engraving and mechanics on the side. He constructed an astronomical clock with an original form of escapement and pendulum, and also made the clock for the Independence Hall belfry. Going to England in 1828, he built scientific novelties for the Adelaide Gallery of Practical Science in London. Michael Faraday was among the great scientists with whom he became acquainted. In 1833 he built and exhibited a magneto-electric machine, but due to his failure to publish a description at the time credit for it went to another. During a nine-year stay in England he acquired several British patents. Returning to Philadelphia in 1837 he built the standard weighing apparatus for the U.S. Mint there and became its curator. In 1843 he joined the U.S. Coast Survey in Washington, D.C., as superintendent of weights and measures, an office held until his death. He was a member of the American Philosophical Society and one of the 50 original members of the National Academy of Sciences. The Franklin Institute awarded him the John Scott medal for his reflecting pyrometer invention.

SAY, sā, **Jean Baptiste,** French economist: b. Lyon, France, Jan. 5, 1767; d. Paris, Nov. 16, 1832. His early life was spent in England where he began a commercial career. The French Revolution called him to Paris, and his acquaintance with and interest in the social philosophy and political economy of his time to the staff of the famous *Courrier de Provence,* the journal of Mirabeau. He was afterward secretary to Étienne Clavière, minister of finance. At the close of the revolution he conducted *La Décade,* a journal in which he presented with great clearness and ability the economic principles of Adam Smith, and such subjects as the public credit, the currency, and taxation. He wrote *Traité d'Économie politique* (1803); *Lettres à Malthus* (1820); and *Cours complet d'Économie politique Pratique* (1828–1830).

SAY, Thomas, American entomologist: b. Philadelphia, Pa., July 27, 1787; d. New Harmony, Ind., Oct. 10, 1834. He was one of the

earliest entomologists and is said to have discovered more species of insects than any naturalist before him. His contributions to natural science were contained in his reports upon his expedition to the coast of Georgia and Florida in 1818, and that as chief geologist to the United States Survey of the Rocky Mountain region under Maj. Stephen Harriman Long in 1819–1820, and have been collected by later naturalists. He was one of the founders of the Academy of Natural Sciences in Philadelphia in 1812. In 1825 he joined Robert Owen in his utopian colony at New Harmony. He is called by many the father of descriptive entomology. He was author of *American Entomology: or Descriptions of the Insects of North America,* 3 vols. (1824–1828).

SAYBROOK (now **DEEP RIVER**), town, Connecticut, in Middlesex County, altitude 5 feet; at the mouth of the Connecticut River; on the New York, New Haven and Hartford Railroad; by rail, 33 miles east of New Haven. Fourth oldest town in Connecticut, it was settled by the English in 1635 on the site of present Old Saybrook. For a long time the Dutch and English vied for possession of it. Indian raids almost destroyed it. In 1701 the Collegiate School was founded, from which Yale University was to evolve. In 1708 the Saybrook Platform of church government was prepared for submission to the legislature. Saybrook is rich in relics of its past: old houses and taverns, tablets identifying the scenes of important events, an ancient cemetery, and the statue of Captain Lion Gardiner (q.v.). The town's name was changed from Saybrook to Deep River in 1947. It includes the village of Deep River. Pop. (1940) 2,332; (1950) 2,570.

SAYBROOK PLATFORM, a declaration of principles adopted in 1708 by the Congregational Church synod at Saybrook; substantially the same as the Cambridge platform (q.v.).

SAYCE, sās, **Archibald Henry,** English Assyriologist: b. Shirehampton, Sept. 25, 1845; d. Feb. 4, 1933. He received his education at Queen's College, Oxford, where he was graduated in 1868. He was elected a fellow in the following year, and became a tutor in 1870. In 1876 he was appointed deputy professor of comparative philology at Oxford, and after 1891 occupied the chair of Assyriology in the same university. He was a member of the Old Testament Revision Company. He was an honorary member of the Asiatic Society of Bengal, the Royal Academy of Spain and the Anthropological Society of Washington.

His larger and more important works are *Assyrian Grammar for Comparative Purposes* (1872); *Principles of Comparative Philology* (1874–1875); *The Astronomy and Astrology of the Babylonians* (1874); *Lectures upon the Assyrian Language and Syllabary* (1877); *Introduction to the Science of Language* (1880); *The Vannic Inscription Deciphered and Translated* (1882); *The Ancient Empires of the East* (1884); *The Origin and Growth of Religion as illustrated by the Religion of the Ancient Babylonians* (1887); *Life and Times of Isaiah* (1889); *The Higher Criticism and the Verdict of the Monuments* (1894); *The Early History of the Hebrews* (1897); *Babylonians and Assyrians* (1900); and *Assuan Papyri* (1906).

He was also author of the popular works: *The Monuments of the Hittites* (1881); *Assyria: its Princes, Priests and People* (1882); *The Hittites* (1889); *The Races of the Old Testament* (1891); *Social Life among the Assyrians* (1900); *Reminiscences* (1923); *The Egypt of the Hebrews and Herodotus* (1895); *Murray's Handbook of Egypt* (1896); and *Israel and the Surrounding Nations* (1898).

SAYRE, Francis Bowes, American public official and diplomat: b. South Bethlehem, Pa., April 30, 1885. He graduated at Williams College in 1909 and at Harvard Law School in 1912. In 1912–1913 he was deputy assistant district attorney of New York County, New York, and between 1914–1917 he was assistant to the president of Williams College. He was a teaching fellow of law at Harvard in 1917–1918 and rose to a professorship in 1924, holding the post from 1924–1934, with leave of absence in 1923–1925 to be adviser to the Siamese government for which he negotiated treaties with nine European governments. He was state commissioner of correction in Massachusetts in 1933 when President Roosevelt appointed him assistant secretary of state in which post he negotiated trade agreements with many countries. From 1939 to 1942 he was high commissioner to the Philippines; he escaped from Corregidor by submarine in February 1942. He was special assistant to the secretary of state, and department director of Foreign Relief and Rehabilitation Operations in 1943, diplomatic adviser to the United Nations Relief and Rehabilitation Administration, 1944–1947; United States Representative in the Trusteeship Council of United Nations with rank of ambassador, 1947–1948; member of United Nations General Assembly, 1947–1948. He married in 1913 Miss Jessie Woodrow Wilson, daughter of President Wilson, in the White House. She died in 1933 and in 1937 he married Mrs. Elizabeth Evans Graves of Washington.

SAYRE, Lewis Albert, American surgeon: b. Battle Hill (now Madison), N. J., Feb. 29, 1820; d. New York, Sept. 21, 1900. He was graduated from Transylvania University in 1839, and three years later from the College of Physicians and Surgeons in New York. He was made professor of orthopedic surgery in the medical college of Bellevue Hospital in 1861, and professor emeritus at its consolidation with the New York University in 1898. In 1854 he successfully performed the first operation in the United States for the removal of the head of the femur in hip-joint disease, and became known as the greatest American orthopedist. His original methods and his invention of instruments used in the treatment of deformed children made his name familiar to the entire medical world.

SAYRE, Stephen, American banker and patriot: b. Long Island, June 12, 1736; d. Virginia, Sept. 27, 1818. He was graduated from the College of New Jersey (Princeton) in 1757, became a merchant and banker in London, attained there considerable influence in political circles, but was committed to the Tower on an unwarranted charge of treason. The affair soon ended in his release; but his banking business failed as a result and he was compelled to withdraw from England. Subsequently he was private secretary to Franklin, went with Arthur Lee's embassy to Berlin and at Copenhagen, Stockholm and St. Petersburg was successful in obtaining supplies

for the furtherance of the cause of independence. He was an opponent of Washington's administration in 1795.

SAYRE, sâr, city, Oklahoma, Beckham County seat, 16 miles west-southwest of Elk City. It is served by the Chicago, Rock Island, and Pacific Railroad and modern highways.

The surrounding area is agricultural, broomcorn, cotton, dairy products, and livestock being the principal commodities. Manufactures include carbon black and gasoline. The city is the market center for the large quantities of broomcorn raised in the area. Sayre Junior College (coeducational) is here. The site was settled in 1901, incorporated as a town in 1903, and as a city in 1910. Pop. (1950) 3,362.

SAYRE, borough, Pennsylvania, in Bradford County, altitude 772 feet; on the north branch of the Susquehanna River and on the Lehigh Valley Railroad; by rail, 95 miles northwest of Wilkes-Barre. Sayre is a railroad town; in 1871 Lehigh Valley Railroad shops gave the place its first industrial impetus, and the shops still are one of the principal sources of employment. Coal and lumber interests are strong, and there are silk mills, knitting mills, and a wheel division of the American Brake Shoe and Foundry Company. The borough has public and parochial schools, a public library, a hospital, and churches of various denominations. It was named in honor of Robert H. Sayre of the Lehigh Valley Railroad. Pop. (1950) 7,735.

SAZONOV, Sergei Dmitrievich, Russian statesman: b. 1866; d. Nice, France, Dec. 25, 1927. Entering the diplomatic service, he was second secretary at the Russian embassy in London from 1890 to 1894 and councillor of embassy 1904–1906. His skilful handling of the difficulties arising from the Dogger Bank incident in 1904 marked him for promotion. From London he went to Rome in 1894 as secretary to the newly-created mission to the Holy See, and in 1906 he returned to Rome as minister to the Vatican. In 1909 he was recalled to Russia to assist M. Isvolsky, then foreign minister, whom he succeeded in 1910. A year later he exchanged views in Paris with the French government, and in 1912 visited the king of England. In the diplomatic crisis preceding World War I, M. Sazonov appeared to be the only allied statesman who saw the one method of averting the impending conflict. In the words of Mr. G. Bernard Shaw, "One man among them keeps his head and looks the facts in the face. That man is Sazonoff, the Russian Secretary for Foreign Affairs" (*Current History,* vol. 1, p. 19). In a telegram from Saint Petersburg dated July 25, 1914 the British ambassador, Sir George Buchanan, informed Sir Edward Grey of an interview with Sazonoff, in the course of which the latter said that "he did not believe Germany really wanted war, but her attitude was decided by ours" [the British attitude]. "If we [Great Britain] took our stand firmly with France and Russia there would be no war. If we failed them now, rivers of blood would flow, and we would in the end be dragged into war. . . . His Excellency said that unfortunately Germany was convinced that she could count upon our neutrality" (*British Blue Book,* dispatch No. 17). M. Sazonov resigned his office in July 1916, and in January 1917 was appointed ambassador to Great Britain, but soon retired. His reminiscences were published in 1927.

SBARETTI, Donatus, Italian R. C. prelate: b. Montefranco, Italy, Nov. 12, 1856; d. Vatican City, April 1, 1939. He was educated at the College of St. Apollinaris, Rome, and was ordained in 1879. For eight years after his ordination he occupied the chair of speculative and moral philosophy in the College of the Propaganda, Rome, and subsequently served as subsecretary of the Propaganda in affairs concerning the United States. He was made private chamberlain to Leo XIII, with title of monsignore, and in 1893–1900 was the first to occupy the office of auditor of the apostolic legation at Washington. He was consecrated bishop of Havana in 1900, appointed apostolic delegate to the Philippines in 1901, titular archbishop of Ephesus later in that year; in 1902 apostolic delegate to Canada, serving to 1914. He was made cardinal in 1916.

SCAB, or **SCABIES,** a skin disease in sheep, analogous to the itch in the human subject and to mange in horses and dogs. It is caused by a parasitic mite, *Sarcoptes scabiei.* See also ITCH.

SCABBARD FISH, the name of certain pelagic fishes, allied to the mackerels, and so called because of their compressed and elongated shape. One is *Lepidopus caudatus,* rare in American waters, but known in the eastern Atlantic, Indian and South Pacific oceans. It is the frostfish of New Zealand, where it comes ashore in the surf on moonlit winter nights, and is caught on the beach by men watching for it. It is a favorite food-fish and reaches a length of five or six feet, but weighs only about six pounds.

Another is the cutlass fish, silver fish or hair tail (*Trichiurus lepturus*), which attains a length of three feet or more, and whose tail ends in a filiform point without a caudal fin. It is found on the American coast from New England to South America, and is silvery, with a golden lateral line and grayish-yellow dorsal; the lower jaw is the longer, with two teeth projecting beyond the upper when the mouth is closed, and the whole armature of the jaws indicates carnivorous habits. It is rarely seen except when found benumbed with cold floating on the surface.

SCAD, a name given to several species of fishes of the family Carangidae; in the United States to *Decapterus punctatus,* a fish about a foot long found along most of our Atlantic coast and abundant southward, where it is a foodfish of some importance.

In England the name belongs to the fish also called horse-mackerel (*Trachurus trachurus*) which appears in large shoals and is dusky olive on the back, the sides variegated by bluish bands. It is also known as saurel, cigar fish, and round robin.

A related species (*Trachurops crumenopthalmus*), common in the West Indies, and known on most tropical coasts, is called big-eyed scad.

SCAEVOLA, sē'vō-lä, **Gaius Mucius,** Roman hero and founder of the plebeian family of Mucii: lived about 500 years B.C. Livy tells how Gaius Mucius, a young patrician, sought to kill Porsena of Clusium, the protector of the expelled Tarquins, who was besieging Rome and had reduced the city to great dis-

tress. Mucius went to the tent of Porsenna to kill him, but mistaking his secretary for the chief plunged his sword into him. Porsenna, in rage, had Mucius brought before him, whereupon the young Roman expressed regret at not having killed Porsenna himself, and told him that other attempts would be made and would be successful. Upon Porsenna threatening to have Mucius burned alive if he did not betray the conspirators, Mucius thrust his right hand into a flame and held it there. Porsenna, in admiration for this fearlessness, ordered the young Roman freed, and the latter in return for his courtesy told Porsenna that 300 Roman youths had sworn to assassinate him or die in the attempt. This so alarmed Porsenna that he raised the siege and withdrew from Rome. Scævola, meaning "the left-handed," was the name bestowed upon Mucius in honor of his deed. Quintus Mucius, called "the augur," a Roman tribune, prætor and consul, d. about 100 B.C., and Quintus Mucius, called "the pontifex," Roman tribune, consul and pontifex maximus, d. 8 B.C., are descended from Caius Mucius Scævola.

SCAFELL, ska-fĕl', or **SCAW FELL,** England, a mountain in the county of Cumberland, bordering on Westmoreland, 13 miles southwest of Keswick. It rises from the centre of the lake region, its two peaks reaching an elevation respectively, of 3,229 and 3,092 feet, making the mountain one of the conspicuous features of the scenery. It consists of granite with a superformation of slate, excepting the summit which is composed of trap porphyry.

SCAGLIOLA, skăl-yō'la, an Italian term for an imitation marble used in columns, walls and floors for surface decoration. It was invented by Guido del Conte in Modena in the early part of the 17th century. It is composed of plaster and glue mixed with splinters (scagliole) of spar, marble, granite, concrete, gypsum, veins of clay, etc., artificially colored and smoothed down and polished to a semblance of the quality of polished marble.

SCAIFE, Walter Bell, American author: b. Pittsburgh, Pa., 10 Sept. 1858. He was graduated at the University of Michigan in 1880 and subsequently studied at Johns Hopkins and at the University of Vienna. Since 1889 he has lectured at Baltimore, Pittsburgh, Washington and Boston on history and other subjects. He published 'American Geographical History, 1492–1892,' 'Florentine Life During the Renaissance,' 'A Dissertation on Law and History,' 'A History of Geographical Latitude' (1889); 'The Boundary Dispute between Maryland and Pennsylvania' (1885); 'The Public Schools of Geneva' (1895); 'Legislative Elections in France' (1898); 'A Century's Labor Legislation in France' (1899); 'Organized Labor in France' (1900); 'Work and Wages in France' (1900); 'Labor Conditions in Switzerland' (1901); 'Auto-Dominis' (in Italian, 1914); 'From Energy to Wisdom' (1917).

SCALA, La, lä skä'lä, Milan, Italy, a historic theatre and opera-house opened in 1778, with accommodation for 3,600 auditors.

SCALD-HEAD, an affection of the scalp, as ringworm of the head, etc., the term being vulgarly applied to various disorders similar in nature. See RINGWORM.

SCALE, from Lat. *scala,* ladder or staircase, *in music,* the tone ladder marking the regular succession of intervals in any given key, from the keynote to the octave, and indicating the relative pitch of tones. See MUSICAL ELEMENTS AND TERMS; MODE.

SCALE INSECTS, certain species of the family *Coccidæ* (see COCCUS). Some species of this family popularly called mealy bugs more often than scales, are readily distinguished by being free-moving, whereas the scales proper are stationary except for a few hours after birth or hatching. The males of the family are remarkable in having a complete metamorphosis (other *Hemiptera* have incomplete, and so do the females of this family), one pair of wings, a pair of hooks replacing the rear wings, and an extra pair of eyes in the adult, instead of mouthparts. The female has six legs when newly hatched, but after molting the legs are wanting and the insects are grub-like, stationary, wingless, and are concealed beneath a powdery, cottony or waxy secretion and the cast-off skins. On account of their appearance some of the species are called gall insects, a name more correctly applied to species of the family *Cynipidæ* and *Gallicolæ,* which produce nut-galls or galls.

The family embraces several species which have been useful to man for many centuries and also some that are troublesome upon cultivated plants. The scarlet grains of Poland are scale insects (*Coccus polonicus*) found on the roots of knawel and were formerly an important article of commerce, being used in dyeing various fabrics. Another species found on the roots of burnet has long been used by the Moors for dyeing wool and silk various tints of pink. Kermes or scarlet grain is the dried body of *Lecanium ilicis* which lives on the young shoots of the kermes oak (*Quercus coccifera*), a low evergreen shrub common from Spain eastward to India. In parts of this region this insect furnished a source of revenue to the people. The females grow about as large as peas and before the eggs are hatched, during May, they are gathered, dropped into vinegar, dried in the sun or in ovens, and sold. They have been used for ages to dye cloth a dark brownish-red, but except locally they are almost entirely superseded by cochineal. See COCCUS.

Cochineal is a species (*Coccus cacti*) of the mealy bug group. It is a native of Mexico where it feeds upon certain species of cactus, especially the nopal (*Opuntia cochinellifera*), a kind of prickly pear (q.v.). It is also found in many regions where this plant has been introduced, notably in the Canaries, Java and the Mediterranean region, in some parts of which it has been cultivated. In Mexico pieces of the cactus covered with the insects are cut out at the close of the dry season and protected until the end of the wet season, when they are used for re-stocking the plantation in October. The females lay about 1,000 eggs, about 99 per cent of which produce females. In December the first crop is gathered and other harvests are made until May when the rainy season begins. The females are brushed off the water, or on hot irons, and dried. They usu-

ally lose more than half their weight in the process. A days' work is represented by about two ounces of dried insects — that is, more than 8,000! These insects have been used for dyeing scarlet and crimson, for which purposes they are unequaled, though coal tar products, being cheaper, more readily procured, and in greater variety, have largely replaced them. They are used also for manufacturing pigments such as lake and carmine (q.v.) and for coloring confectionery. See COCHINEAL.

Several other species have been used for dyeing, some being employed by the ancient Egyptians, Jews and Persians for giving the brilliancy or delicacy of tint to certain fabrics formerly highly valued by these nations and the peoples embraced in their commerce.

Other members of the family are noted for their wax, which is used in some countries for candles, varnishes, sealing wax, lacquer and many other purposes. The wax insect of China (*Coccus sinensis*) is a small white species which lives upon sumac and other trees upon the branches of which it deposits its secretion. This resembles hoar frost during June, but becomes somewhat darker and more continuous by August when it is scraped off and melted in boiling water. After straining and cooling it is ready for use. The French have introduced this species into Algeria. In South America another species is locally but not commercially, important as a source of wax and in other countries are several species that might become similarly useful. But the principal species are the lac or shell-lac insects of Asia. See LAC.

Among the species considered troublesome upon cultivated plants perhaps the cottony cushion scale (*Icerya purchasi*) is perhaps the most noted in the United States. This is an Australian insect which was accidentally introduced into California where, being free from the conditions that held it under control in its native habitat it spread rapidly upon orange, lemon and other citrus trees to the dismay of orchardists. It was found that certain species of ladybird beetles (q.v.) play important rôles in checking the spread of this scale in Australia; so, some were imported in the hope that they would eradicate the scale in California. They did. The scale is now practically extinct in California and the lady-bird beetles, being deprived of their food supply, have followed it, since they seem to be unable to adapt themselves to other foods. This is one of the most remarkable instances of man's intervention to bring natural controls to his aid instead of resorting to artificial methods which are frequently cumbersome or unsatisfactory.

The armored scales of the sub-family *Diaspinæ* are generally of small size, but being exceedingly prolific and voracious are of ill-repute. They are generally flattened or slightly convex, covered with a parchment-like membrane, and are of many shapes. The larvæ are either hatched from eggs or are born. They crawl to a suitable place to feed, usually before they are a day old, and become fixed. They are tiny, flat, six-legged larvæ with a pair of feelers and with long sucking beaks. Soon waxy threads appear, coalesce and cover the creatures. After molting the larvæ are legless. After the second molt the males can be readily recognized, being a pupa with wings, legs and antennæ visible; the females become still more grub-like. The male soon emerges, flies a short time, pairs and dies. In some cases the females hibernate, in others they lay eggs, in others bear young, sometimes there may be several generations in a season. Some of the best-known species are the oyster-shell scale, especially *Mytilaspis pomorum*, which is well known upon apple, lilac, willow and other trees. They are named from the shape of the scale, which resembles the shell of some kinds of oysters. This species winters in the egg, the young appear in May, and in the North there is only one brood; two in the South where the insects are believed to hibernate. A very similar species lives upon citrus fruits, and specimens may often be found upon oranges and lemons, especially those that come from the Mediterranean region. The San José scale (*Aspidiotus perniciosus*) is viviparous and enormously productive. It lives upon the woody members of the order *Rosaceæ*, for example, apple, cherry, rose and pear, and upon currants, gooseberries, elm, chestnut, oak, walnut and many other trees and shrubs. The scurfy scale (*Chionaspis furfurus*) is an oval scale with the cast skin at the small end and is frequently found upon apple and pear trees. The red scale of the orange is a close relative of the San José scale and is well known in California, Florida, etc. See ORANGE.

The cottony maple scale (*Pulvinaria innumerabilis*) is often found on Virginia creeper, grapevines, and some other plants, as well as on maples. It is a soft scale which is usually rather conspicuous in spring from its cottony appearance upon the young growths. The "cotton" is really a gum since it can be drawn out into cobweb-like threads. The black scale (*Lecanium oleæ*) is another soft scale which is well known to California olive and orange growers.

Several species of scale insects are found in greenhouses and nurseries devoted to ornamental plants. But they present no more remarkable features in life-history or habits than the preceding, and being of somewhat smaller importance need not be discussed specifically.

Where the natural controls seem to be inadequate to cope with the species various artificial methods have been tested to determine their efficacy. But in many instances these are so cumbersome, expensive, dangerous either to plant or operator, and difficult to apply intelligently, that they have been discarded. Spraying and fumigation are the principal ones in vogue. But it seems highly probable that in many instances the natural controls would hold the scales in check. Man has, however, not yet discovered these controls except in a few cases and in most of these has not made use of them more than experimentally.

Consult numerous bulletins of the agricultural experiment stations and the United States Department of Agriculture; also references under INSECTICIDE.

M. G. KAINS.

SCALE-TAIL, an African flying squirrel of the family *Anomaluridæ*, distinguished from the true squirrels by dentition and various other peculiarities, and especially by the possession of a series of strong keeled scales at the root of the tail, which seem to serve as an aid

in climbing. There are several genera and species, of which the best known is *Anomalurus pedi* of the Gold Coast, which is black and white, and is regarded as a delicacy by the natives. The food and habits are similar to those of the northern flying-squirrels

SCALES. See BALANCE.

SCALIGER, skăl'ĭ-jẽr, **Joseph Justus,** French scholar and author: b. Agen, France, 4 Aug. 1540; d. Leyden, France, 21 Jan. 1609. He was the 10th son of his learned father, Julius Cæsar Scaliger (q.v.), and received from him a fine classical education, as well as a boastful and arrogant nature. He studied Latin at Bordeaux, and Greek at Paris. According to Henisius, he shut himself into his room and committed to memory the whole of Homer in 21 days; he memorized the rest of the Greek poets in three months and the entire body of Greek literature in two years. It was his boast that he was equally familiar with 13 languages. In his 22d year he was converted to Protestantism, a fact which probably retarded his advancement in France. From this period until 1578 he traveled extensively making a poor living from his teaching and writings, but refusing the money offered him by admiring patrons. In 1578 he became professor of belles-lettres at Leyden, a position which he held until his death. Joseph Scaliger's most important works are upon chronology. His 'De Emendatione Temporum' (1583) gave the first complete scientific chronology, and for this work, with his 'Thesaurus Temporum' (1609), and on account of his discovery of the Julian Period, he deserves to be called the founder of the science of chronology. He also annotated the principal works of the chief Latin writers.

SCALIGER, Julius Cæsar, Italian classical scholar: b. Riva, Lake Garda, 23 April 1484; d. Agen, France, 21 Oct. 1558. He is generally accepted as the son of Bendetto Bordoni, a miniature painter of Padua, but Scaliger claimed descent from the Scaligeri princes of Verona, as did his son, Joseph Justus Scaliger. The elder Scaliger, according to his own account, was a page of Emperor Maximilian for 17 years, then received a pension, studied at Bologna, commanded a squadron under the French viceroy, studied natural law, and in 1525 accompanied the bishop of Agen to his diocese in France where he settled as physician. In 1530 he married a lady of rank and from that time put forth pretentious claims as to his ancestry. He was a man of unusually great learning, a versatile Latin poet, but bold and arrogant, so that while his writings brought him admirers among the scholars of his day, his personal conduct gained him many enemies. His principal works include commentaries on the work of Hippocrates 'De Insamnis' (1538); of Aristotle, 'De Plantis' and Theophrastus, 'De Causis Plantarum' (1566); an attack on Erasmus, 'Oratio pro Cicerone contra Erasmum' (1531), 'De Causis Linguæ Latinæ' (1540); 'Poetices Libri VII' (1561).

SCALLOP, a well-known bivalve mollusk. The scallops form a family (*Pectinidæ*) related to the oysters, which they resemble in having a single adductor muscle. The genus *Pecten,* which in the wide sense is nearly coextensive with the family, has the following characteristics: The shells are more or less orbicular, with an ear developed on each side of the umbo, making a straight hinge-line, generally ornamented externally with more or less developed radiating ribs. The hinge-teeth are lamellar, but usually small and obscure, the principal ligament is internal and solid, and the muscle-star is single. The mantle margins are open all around, reduplicated and, besides a fringe of tactile filaments, bear numerous conspicuous eyes of a brilliant blue or silvery lustre. These eyes are the most complex known among the *Pelecypoda* and consist of a nervous layer, a choroid coat, lens and cornea and receive an optic nerve from the circumpallial trunk. The gills are delicate and of peculiar structure, the foot small and papilliform and in the young has a byssus gland, and the genital ducts open into the kidneys or near their apertures. Only the posterior adductor muscle is present, and this is large, round, central, and remarkable from its constitution in part of striated and in part of nonstriated fibres. Scallops are remarkable, especially when young, for their activity, and swim in a peculiar jumping fashion by opening and powerfully closing the shell valves as though flying, thus forcing out the contained water and propelling themselves forward. As they become older and the shells heavier they are more quiescent. Fully 200 living and a still greater number of fossil species are known beginning in the Carboniferous strata. Perhaps 40 species occur in North American waters, the great majority southward and in moderately deep water. Several of our own and foreign species are of commercial importance, furnishing the well-known scallops of the markets. *P. jacobæus,* a native of the Mediterranean, is the scallop shell which pilgrims were accustomed to wear in front of their hat in token of having visited the shrine of Saint James at Compostella.

Although the richly colored and beautifully formed shells of the scallops are much used in fancy work of various kinds, these mollusks derive their commercial importance from the use of the muscle for food. Before the advent of the white man they were largely gathered for this purpose by the Indians. The principal fisheries are on the coast of Maine, in Long Island Sound, Buzzard Bay and contiguous waters, and on the coasts of New Jersey and California, the first two having the greatest magnitude. South of Cape Cod *Pecten irradians,* which has the shell marked with about 20 prominent radiating ribs on each side, is the species sought. This lives especially in the shoal waters of the bays or on flats in the Sound. Scallops vary greatly in abundance from year to year and the seat of the fisheries changes accordingly, some formerly favorite grounds being abandoned and others developed. The commercial scallop fishery of Maine originated about 1880 and has since developed into an important industry at many points east of Casco Bay. Here the giant scallop (*P. magellanicus*) is the species sought. This is much larger than *P. irradians,* and the valves are marked with numerous fine radiating lines, the lower valve being nearly flat and white and the upper convex and brown. This species lives in deeper water and like the other changes its feeding ground. Scallops are now taken almost exclusively in small dredges, resembling in most

features the oyster dredge, and pulled over the ground by means of small boats; larger vessels when used serve chiefly for transportation, etc. The fishing season varies; south of Cape Cod it covers the cold months, but about Mount Desert the bulk of the catch is made during July and August.

Consult Ingersoll, 'The Fisheries Industries of the United States,' Sec. V (Washington 1887); Smith, 'The Giant Scallop Fishery of Maine'; Bulletin United States Fish Commission 1889 (1891); Stearns, *Overland Monthly* (1873); Zittel and Eastman, 'Textbook of Palæontology' (Vol. I, London 1900); Risser, 'Thirty-first Report of the Commissioner of Rhode Island Fisheries' (Providence 1901).

SCALP, the outer covering or integument of the upper part of the skull or brain-case. Except in the fact that hair in both sexes grows more luxuriantly on the scalp than elsewhere the skin of the scalp differs but slightly from ordinary skin. But besides its constituent of skin, the scalp is composed of the expanded tendon of the occipito-frontalis muscle, and of intermediate cellular tissue and blood-vessels. Injuries of the scalp, however slight, must be carefully watched, for they may be followed by erysipelas, inflammation, suppuration or pyæmia that may easily prove fatal. Prompt antiseptic dressing lessens the danger in such accidents. In the treatment of scalp-wounds no part of the scalp should be cut or torn away; and, if possible, stitches should be avoided, as plasters and bandages will generally keep the separated parts in apposition. Burns of the scalp are very liable to be followed by erysipelas and diffuse inflammation, but the brain is comparatively seldom affected in these cases. Tumors of the scalp are not uncommon, the most frequent being the cutaneous cysts popularly known as wens, and vascular tumors. Parasitic diseases also affect the scalp, and require special treatment. Catarrhal inflammation of the hair-follicle and other hair-destroying diseases result from micro-organisms. See DANDRUFF; PITYRIASIS; RINGWORM.

SCALPER, a common term in the United States applied to any person who buys railroad, theatre or steamship tickets at a discount from people unable to use them, and sells them again at an advance on the price he paid for them. Theatres and transportation companies have devised various plans to break up this trade, and in some States laws have been passed forbidding the sale of railroad tickets at cut-rate prices.

SCALPING, the act of partly cutting and partly tearing off the skin of the head, with the hair attached, of a living or a dead victim. Scalping was practised in early times, by most of the savage and barbarous nations of the eastern hemisphere, as the Scythians, Gauls and other wild peoples of Asia and Europe, and later by the American Indians residing principally in the eastern United States and the lower Saint Lawrence region. It seems to have been unknown until comparatively recent times, in the great plains regions; and it was little practised among the Pueblo and other more cultured tribes of the United States. It was unknown south of the Rio Grande except where introduced by American tribes; and was absent from Central and South America. Nor was scalping practised in the Canadian Northwest or along the whole Pacific Coast. Sometimes the entire head was taken in lieu of the scalp. After the scalp was taken, it was tanned and then stretched on a small hoop of wood, and the side opposite to that having the hair was painted in various colors, and even the hair was tinted likewise. Sometimes the portrait or the hieroglyphic device of the person scalped was placed on it. Persons scalped did not always die from the effect. Scalps were regarded as trophies of victory and prowess. Joutel relates that in 1687 among the Cenis of Texas, a scalp was waved or offered in ceremony to the four quarters of the world, and that tobacco and hominy were offered to the scalps that were paraded. In 1703, Bienville offered 10 «escus» (*écus*, about 10 crowns) for every scalp of a man killed or prisoner taken of the Chetimachas and Alibamons (Alibamas). The American colonies offered bounties for scalps. In 1724 Massachusetts offered 100 pounds sterling (about $500) for Indian scalps; 30 years later, during the so-called French and Indian war, the French offered a bounty for British scalps, and the colonists for Indian scalps. In 1755, 40 pounds sterling (about $200) was offered by Massachusetts for the scalps of male Indians over 12 years of age, and 20 pounds sterling (about $100) for the scalps of women and children.

This official encouragement to scalping led to the extension of the practice to tribes that had never before indulged in it. Naturally among these latter tribes the scalp had little or no ceremonial significance as it seems to have had among eastern tribes. Scalping appears to have probably arisen out of head-hunting which seems to have been common in parts of America at an early date. Among the tribes originally addicted to scalp-taking, a scalp dance formed a part of the ceremonies held on the return of a war party. In this dance the women, not the men, carried the scalps. The scalp was not, as popularly supposed, a standard by which to judge the powers of the warrior.

Consult Braunschweig, 'Scalping' (Smithsonian Reports 1906–07); Friederici, 'Skalpieren und ähnliche Kriegsgebräuche in Amerika' (1906); Handbook of American Indians, 'Scalping' (Washington 1910).

SCALY ANT-EATER. See MANTIS.

SCAMANDER, skạ-măn'dẻr (ancient XANTHUS), Turkey in Asia, a small stream in the Troad, rising near the city of Ilion. It had two sources, one of which was hot, the other cold. Strabo asserts, however, that it had but one source, which was in Mount Ida. Its direction was west-northwest, and about two miles from its mouth it received the small river Simois; it emptied into the Hellespont. Since the beginning of the present era these rivers have had separate courses. The Scamander is sometimes identified with the Mendere or Meander (q.v.).

SCAMMONY, a gum-resin obtained from the *Convolvulus scammonia*, native to the bushy wastes of western Asia. This is a climbing plant with irregularly arrow-shaped leaves, white or purplish flowers like morning-glories, and a fleshy tapering perennial root. When in flower incisions are made obliquely in the upper part of this root, and shells fastened below the gashes, in which the sap is caught as it exudes. They

are then emptied, the juice added to scrapings from the root, thoroughly mixed, dried, and kneaded into cakes. Scammony is much adulterated, but when pure or "virgin" is greenish-gray or blackish in color, internally porous and of a resinous lustre, breaking with an angular fracture and translucent in thin pieces. It has a peculiar, somewhat cheeselike odor and an acrid taste. Different kinds of the drug are named after the districts in which it is collected and the place of export. Scammony is a strong purgative usually used in combination with other medicines, and supposed to have been known to the Greeks as early as the 3d century B.C.; also to have been one of the medicines recommended by Helias to King Alfred the Great.

SCAMOZZI, skä-môt'tsê, **Vincenzo,** Italian architect: b. Vicenza, 1552; d. Venice, 1616. He was taught by his father, also an architect, and by Palladio and Jacopo Sansovino, at Venice; and at Rome he studied ancient monuments. Returning in 1583, he was commissioned to erect a monument to the family of Marc Antonio Barbari, in the church of the Caritá, and so much was this work approved that he was appointed to finish the grand library at Saint Mark's, to build the Trissino Palace at Vicenza and the Cornaro Palace on the Grand Canal, Venice. By this time Scamozzi's fame had spread over Europe and he was in great demand. He built the Ravaschieri Palace at Genoa, and added the second story to the Palazzo Strozzi at Florence (1594). About 1604 he designed the cathedral of Salzburg, Austria, and a part of the Schloss at Prague, Bohemia.

SCAMOZZI IONIC ORDER, in architecture, a type of the Ionic order in which the four faces of the capital are identical in design. It was named for Vincenzo Scamozzi (q.v.) who, however, did not invent it. The spiral volutes on all four faces meet at an angle in the corners, and at the center curve down into the top of the echinus instead of joining in a horizontal band. A rosette usually occupies the space which, in the Ionic order, is filled by the band connecting the volutes. In some instances the centers of the volutes are connected by garlands.

SCANDAL, in law, any injurious statement concerning another person which may constitute the foundation for legal action. In the popular meaning of the term, scandal is the report, whether true or false, of disgraceful behavior on the part of a person of good reputation, or malicious gossip leading to the loss of reputation by the implicated individual. In England under statutes of Edward I and Richard II, *scandalum magnatum,* the defamation of men in high official position, was an offense punishable by the recovery of damages. Although these statutes were long in desuetude, they were not abolished until 1887.

SCANDERBEG or **SKANDERBEG,** skăn'dĕr-bĕg, Albanian chief and national hero: b. about 1403; d. Lesh (Ital. Alessio), Albania, Jan. 17, 1468. He was the fourth son of John Castriota, a high official of Serb origin, and his real name was George Castriota. An uncle, having married into one of the leading Albanian families, commanded the Albanian fortress of Kroja. When the Turks began to occupy Albania and a Turkish governor occupied Kroja as his headquarters, the 11-year-old George was sent to Constantinople as one of the hostages. There he was educated as a Moslem and given the name and title of Iskender (Alexander) Bey, corrupted by his compatriots to Scanderbeg. Under the Turks he made a distinguished record as administrator and soldier, governing a sanjak and fighting in wars with the Serbs and the Venetian Republic. While campaigning against the Hungarian János Hunyadi in 1443, he learned that his native land had revolted. From that moment his chief concern was the liberation of Albania. He entered into a secret agreement with János Hunyadi, pretended to have suffered a serious defeat and retreated to the fortress of Kroja. Once in possession, he declared himself a Christian, rallied the Albanian clans, married the daughter of a local patriot chieftain and, with the assistance of his brother-in-law Stephen Crnojevich, ruler of Montenegro, successfully challenged the Turkish power. Venice subsidized him as an ally against the traditional enemy. He also received the support of the pope and the king of Naples. Mohammed II finally concluded a 10-year armistice with him in 1461, acknowledging the independence of Albania and Epirus. Unfortunately, at the behest of Pope Pius II, who was organizing a crusade against the Turks, Scanderbeg soon broke the truce, and when the pope died in 1464 and the crusade withered in the bud, he found himself abandoned by his Western allies. Mohammed the Great himself laid siege to Kroja in 1466, and Scanderbeg hurried to Rome to entreat the aid of Pope Paul II, but without avail. He returned to Albania and died in the Venetian colony of Alessio in 1468. The Turks then succeeded in reconquering all of Albania except Kroja which Scanderbeg's son Giovanni ceded to Venice.

SCANDINAVIA, a general designation for the three north European kingdoms, Denmark, Norway and Sweden (qq.v.), sometimes applied in a more restricted sense to the two latter only. In the Middle Ages the name of Northmen was bestowed indiscriminately on the inhabitants of the three countries, whose closely related languages and common mode of life and political fortunes afforded sufficient basis for considering them one people. As a geographical term, Scandinavia is rapidly passing out of use, but the appellation is still employed in an ethnographic, and especially in a literary sense.

SCANDINAVIAN LANGUAGE AND LITERATURE. See DANISH LANGUAGE; DANISH LITERATURE; NORWEGIAN LANGUAGE; NORWEGIAN LITERATURE; SWEDISH LANGUAGE; SWEDISH LITERATURE.

SCANDINAVIAN MUSIC. For centuries, any knowledge of the life and culture of the ancient peoples of the Scandinavian countries remained in almost complete darkness. Their weird legends and mythology, their songs and epic poems, and their sagas were known to the Norsemen themselves, who inhabited and still inhabit the North; to the rest of Europe they were unknown. The earliest historical records of these Northern peoples are scant and few. They are to be found in the fragmentary accounts of the voyages (c.330 B.C.) of Pytheas of Massilia (Marseille), and are preserved for us through

the writings of Strabo and Pliny. Toward the beginning of the Christian era, Roman and Greek writers like Julius Caesar, Tacitus, Jordanes, and Procopius mentioned the people of the North. But these records, extending from the time of Pytheas to Procopius, and covering a span of about 900 years, in which the Greek and Roman cultures reached their glory and slow decline, give us very little information about any civilization or culture beyond the nearest neighbors of the Roman Empire. Aristoxenus and others wrote very learnedly of the old Hellenic and Roman music, regarding the content of which we still know very little. Concerning the ancient Norsemen and their music nothing was known. But through this mist comes a gleam from a remote age, the Bronze Age (c.2000–1000 B.C.). A strange and high culture is revealed through the many finds in graves and burial mounds. The rarest of these finds, in an artistic and musical sense, is the mighty bronze horn, the lur. These horns, some over 7½ feet long, are masterpieces of bronze casting and show a craftsmanship which could scarcely be surpassed today. The ancient bronze lur is without doubt the oldest artistic musical instrument so far found in the world. It was cast in molds, in several pieces; these were then joined with interlacing rivets. The shape of the whole tube is conical, gradually expanding from the mouthpiece to the bell, which abruptly bends off to the sides, making a flat front. That the early Norsemen were able, with their crude and scant technical resources, to cast bronze in several gradually expanding, conically shaped, and gracefully bent tubes with comparatively thin walls, where the one piece must fit exactly into the other, can only excite our admiration for the masterful way in which it was done. The lur has, as a rule, been found in pairs tuned to the same pitch, these pitches again varying in the different pairs of horns. The pitches are G, B, C, E flat, and E. The contour of the lur is not straight, but bent somewhat to the shape of an S. Artistically interesting is the fact that each horn is bent or swung opposite to its mate. Thus the horn of the player standing to the right bends from the mouthpiece, back over his right shoulder, then up and forward over his head. The horn of the player to the left bends to the left, and then up. This bending of a pair of horns opposite to each other has no effect on the playing, but merely shows the artistic sense of the old Nordic instrument makers and again bears proof of their remarkable knowledge of bronze casting. The tonal range of the lur is greater than that of any modern metal blow instrument except the French horn. Some well-preserved specimens have a range of 4½ octaves, or from D below low C to G under high C. Many of the horns are in such excellent condition that they can still be blown. They produce a tone both powerful and mellow, not unlike the modern bass trombone, but with a distinct and noble quality entirely their own. They possess all the so-called natural tones, that is, tones produced with the lips only. Good specimens can produce 22 of these tones. They have, of course, no valves. The mouthpiece is remarkable in its similarity to that of a modern trombone, only a little more shallow. It is difficult indeed to calculate how many generations passed before these old masters were able to cast their bronze horns with such consummate skill and artistic beauty, thus proving themselves the possessors of the extraordinary acoustical knowledge which enabled them at will to cast these instruments to their different pitches. When the average extant lur can easily produce 12 tones, and some well-preserved specimens 22 to 23 tones, then we have a right to assume that the old horn blowers were able to play at least 8 of the 12. When then several pairs of the horns are found together, and these in pairs tuned to different pitches, we again have a right to assume that the Nordic Bronze Age people knew a certain primitive harmony; for example, a major triad, and perhaps a minor one. By merely blowing 2 or 4 or 6 of these horns in their different pitches at the same time, both melody and a certain crude harmony could be had, even quite accidentally. The horns unearthed in Norway and Sweden are older than those found in Denmark, where, however, the greater number and best-preserved specimens so far have been found. It is interesting to note that in carvings on stone monuments and in some of the old mythological poems, the lur is mentioned as the Horn of the Gods.

Archeologists generally agree that, as a rule, very few copies are found of antique things compared with what the people actually had. Consequently the lur must have been an instrument common to all the people of the then inhabited parts of Norway, Denmark, and Sweden. These tangible proofs of an old music culture, flourishing some 3,500 years ago, and with so much mechanical and acoustical knowledge, the equal of which in instrument making was only attained by the rest of Europe in medieval times, furnish the historical background of Scandinavian music. With the advance of new cultures and civilizations, the life of the Nordic Bronze Age people slowly changed. The old lur fell into disuse, soon to sleep its age-old sleep in bogs and burial mounds. At the dawn of Christianity, other musical instruments developed, and poetry and singing became more and more the expressive medium of the people's spiritual and emotional life.

Early history and tradition in the North centered around the southern parts of Norway and Sweden, the adjacent Danish islands, and the Cimbrian Peninsula. In the dim past, a common language, mythology, and customs were shared by the three Scandinavian peoples. At the beginning of the Christian era, none of them was as yet a separate nation or realm. From about the beginning of the 8th century, they appear more and more on Europe's historical scene as three distinct nations. Language and customs, however, remained the same for several hundred years. As late as the 11th and 12th centuries, linguistic differences were still very slight, but characteristic changes began to take definite shapes, and slowly there were formed the three dialects which gradually evolved into the Norwegian, Swedish, and Danish languages (qq.v.). But even in our time most people from the three countries can understand one another without difficulty.

During the turbulent years of the Viking age (c.800–1000 A.D.), contact with the other European countries became more firmly established. Most important for Norway and Denmark was the close connection with the people of the British Isles, and to a somewhat less degree, the contact of Sweden and parts of Finland with southeastern Europe. But it was the west European contact

which became the more important. When the Norsemen came to the British Isles, they brought their folk music with them, and here it influenced and was in turn influenced by the native music. Already the Celts and the Norsemen had a music culture developed and apart from the Greek-Roman music, and both in the British Isles and in the Scandinavian countries this culture and tradition was of a great antiquity. Thus it follows that shortly after 1188, the Welsh scholar, Giraldus Cambrensis, wrote that the people of northern England sang in duet, and that the people of Wales sang with as many voices as there were singers—forms of singing they had learned from the Norwegians and Danes who had settled there. (See NORWEGIAN MUSIC.)

The old Norsemen loved poetry, singing, and harp playing. The great episodes from the sagas, especially *Volsunga Saga,* have often been used for artistic treatment by Norwegian craftsmen. Particularly such incidents as Sigurd, q.v. (Siegfried) and the dragon Fafnir, and King Gunnar in the snake pit are depicted in beautiful 900-year-old wood carvings on door jambs of Norwegian churches; of great importance are the carvings which show different forms of the old Nordic harps. In the old *Beowulf* poem, musical instruments are mentioned, such as the hearpe, the gamenwudu, and the gleobeam, which leads attention to the Finnish kantele, often in Finnish folk poesy called the joymaker. The kantele belongs to the psaltery group of instruments. Other instruments used in the North were the fithla (fiddle), and the gigja (gigue), forerunners of the violin; the Icelandic langspil, the Norwegian langeleik or langhørpu, both related to the old monochord; the organistrum, the symphonia (cinfonie, sinfon, fon), flute, bagpipe, drum, cow horn, goat horn and reed flute, the nyckelharpa or keyboard fiddle (see SWEDISH MUSIC). In Denmark, and especially in Sweden, the humle (hommel), a zitherlike instrument, was much in use. Another instrument is the tallharpa, a relic of the old bowed lyre, and played mostly by descendants of Swedish settlers on the Baltic east coast. According to the Finnish musicologist, Otto Andersson (who in 1903 rediscovered the instrument), its name "tall harp" is derived from the fact that originally its 3 to 5 strings were made from horsehair, which in Swedish and Norwegian is called *tagel,* or in the vernacular, *tall.* It is believed the tallharpa also was used in Norway. At the beginning of the 20th century, it was still very popular on the Estonian Islands, where it is often called Swedish harp or Swedish kantele (rootig kantele). The instrument probably originated in Sweden. In Denmark and Sweden the violin did not develop along the line and form that it did in Norway, until there, at the end of the 15th century, it evolved into the hardingfele (see NORWEGIAN MUSIC).

The church was of influence in providing a common religious music for the Scandinavian countries. But certain compositions appeared in one country and not in another, as for example the *Hymn to St. Knud* (Canute IV) in Denmark, or the sequence *Lux Illuxit Laetabunda* which was composed and sung in Norway in honor of the martyr king, Olaf II, or St. Olaf, long before his sanctity was much known outside the country. Or the old mythological poems were chanted to tunes which undoubtedly had their origin in church music. Thus the old poem *Voluspá* was sung to a melody very similar to a Gregorian chant heard every Wednesday, the *Lamentations of Jeremiah.* The folk songs wandering over the North often had the same origin, and like true folk songs, they found a home wherever they were sung by the people, the story, and often the melody, changing a little with the new locality and language. In Norway, Sweden, and Denmark the folk songs eventually acquired their own distinct national character. In Finland the tunes for the cantos (runot) were sung; here outside influence was also very slight. The Nordic folk music had their three distinct phases—rhythm, melody, and harmony—corresponding to the drum, the flute, and the lyre. The rhythm shows that 7/4 and 5/4 time were often used. Most of the older folk songs were originally sung to dancing. This song-dance, to which the epic-lyric folk song was sung, is still danced and sung in its original form in the Faeroe Islands today. It can be traced back to the old French ring dances like the caroles and especially the branles; also they are similar to the old Greek dances as described by Homer in the *Iliad,* and still danced at Megara and Elevsis in Greece. The models for the old Nordic epic-lyric folk songs were the French *chansons d'histoire* and the *chansons de toile.* To make the story-relating Nordic songs suitable for dancing, however, refrains were used, these often being taken from still older verses. From France (Normandy) the song-dance went to England, from there to Norway, and thence to the then Norwegian possessions—Iceland, the Faeroe Islands, and the Shetland Islands. To Denmark and Sweden similar dances came mostly from Germany.

Iceland lost in the short space of 12 years (1402–1414), through the Black Death, about two thirds of its population. This calamity, in an already sparsely settled country, is undoubtedly one reason why so many of the oldest Icelandic folk songs and melodies have been lost. But among those left are found tunes and remnants of scales that speak of high antiquity, and show characteristics different from, and antedating, the church music in the North. Since Iceland had little musical contact with the outer world, these melodies have kept their original form and tonality. The old way of singing in parallel fourths and fifths is still in vogue in the so-called *tvisøngur.* The folk songs include love songs, lullabies, satirical songs, and nature songs. Of a later date are the *vikivaki søngur,* which flourished from the 15th to 18th century. The *vikivaki* songs were as a rule dance-songs, and were sung during the eves preceding the great holy days like Easter and especially Christmas. These meetings or festivities were called *vikivakar;* the origin of the name has not been satisfactorily ascertained. *Vikivaki* songs are often quite complicated in their structure, with remnants of the style found in the old saga poetry, their contents varying from the serious to the humorous and gay. Already in the 11th century the song dances were mentioned in Icelandic writings. The *vikivaki* songs took the place of the older dance-songs. Gradually, as the years went by, the quality of the songs, and the singing and dancing, assumed a more and more improper and crude character, although it never reached the degrading forms it did in Germany. However, it caused the Icelandic clergy to wage such a strong opposition against the continuance of the *vikivaki* meetings

that they finally, by royal decree in 1746, succeeded in completely abolishing them. This was also another reason why so many of the old Icelandic folk songs were forgotten. Most of the old and the newer folk songs have been collected by Dr. Olafur Davidsson (1862–1903). Other collectors are Sveinbjørn Sveinbjørnsson (1847–1927), and Dr. Bjarni Thorsteinsson (1861–1938).

In the Shetland Islands, the Hjaltland of the old Norwegians, the song-dances were kept alive until the middle of the 18th century. The texts of the songs dealt mostly with the kings and heroes of the old Norwegian history, in a language peculiarly half Norwegian and half English. Late in the 18th century the only remaining one of these songs—the ancient *Hildinakvad* (kvad-song or poem)—was written down at the island of Foula.

In the Faeroe Islands instrumental music was practically unknown until the end of the 19th century. Here we find the old song-dances as they were sung and danced a thousand years ago; also the oldest and most complete epic folk songs and melodies in Europe. The Faeroe dance's traditional steps, the same as in the French branles, are still the fundamental accompaniment to the old ballades. The song leader sings the many verses and the rest of the dancers in the ring sing the refrain, the *stev;* or both verse and refrain are sung by all the dancers. While the old ring-dances elsewhere in medieval Europe were danced to lyric verses—love songs—and often accompanied by instrumental music, the majority of the old Faeroe songs were of a story-relating and heroic character, their contents taken from the history of the old Norwegian kings, from the mythology and from the sagas. In the mighty *Sjurtharkvaethi,* the story is about Sigurd Fafnirsbani (Siegfried) and his adventures, and one of its many tunes is perhaps the oldest folk song melody known in Europe. To the islanders, the contents of the dance-songs were their only source of historical information, and then largely old Norwegian history. It was also their introduction to the old Nordic world of myth and saga. The Faeroeic dance-songs are full of dramatic life and emotional power. They have quite a characteristic saying in the islands: "No step without a tone." Most of the texts and melodies have now been written down: the *Sjurtharkvaethi* was recorded by the Dane, Hans Christian Lyngbye (1782–1837), and printed in 1820; and these songs and many others by the Faeroese, Venceslaus Ulricus Hammershaimb (1819–1909), and printed in two volumes, *Faeroeic Songs* (*Faerøske Kvaeder,* 1851–1855).

The contents of the older Norwegian dance-songs and ballades have, quite naturally, much in common with the Faeroeic songs. Motifs from the old Edda poems are used in the songs about Sigurd Svein (Siegfried); or songs were about Charlemagne and the valiant Roland at the Battle of Roncesvalles (778); or the songs could be about trolls and ogres, heroes, and princesses, visionary and religious songs. It is of interest to note that the Nordic lyric dance-songs have merged with the epic songs and served as their introduction or refrain (the *stev*). They create the mood, the background for the song-story. In the North the epic song reached its highest development. Of romantic songs about knights and ladies, the so-called *riddervise,* Denmark and Sweden have the best. In Denmark, the folk songs were written down at a comparatively early date; in Sweden and Finland, somewhat later; and in Norway, at first towards the middle of the 19th century. Outside of the pure folk music in the North, foreign influences are apparent in the art-music. English, French, Dutch, Italian, and German musicians were introduced, and in many instances left their mark on Scandinavian music. Toward the end of the 18th and during the 19th century the newer, national schools were inaugurated. This movement started largely with Edvard Grieg. No one has made a more artistic use of the folk music than he. Grieg and Jean Sibelius are still the two greatest exponents of these new schools. In the mid-20th century, one can no longer speak of Scandinavian music as a whole, but of definite branches thereof—Norwegian, Danish, Swedish, and Finnish music—all having their roots in a common Nordic past with age-old traditions. See also separate articles on the music of the various Scandinavian countries.

AUGUST WERNER,
Professor of Music, University of Washington.

SCANDINAVIAN MYTHOLOGY. The pagan beliefs of Scandinavia have been preserved by Christian writers and are therefore only fragmentarily known. Thanks, however, to the diligence of medieval Icelandic scholars, they are more fully preserved than those of any other Germanic tribe. The chief sources of information are the two Eddas (q.v.): the *Elder,* or *Poetic, Edda,* a collection of some 30 mythological and heroic poems discovered in 1643, and probably composed between the 9th and 13th centuries; and the *Younger,* or *Prose, Edda,* which was written by Snorri Sturluson (1178–1241, q.v.) as a handbook of poetics. Supplementing these two major sources are the poems of the *skalds,* or court poets, who even after the coming of Christianity, used mythological allusions to adorn their verses; a few runic inscriptions, occasional comments by classical writers (especially Tacitus in his *Germania*), the writings of the German historian, Adam of Bremen (d. c.1076), and the Danish historian, Saxo Grammaticus (1150?–?1220), the sagas of Norway and Iceland, Finnish folklore, and the evidence of pagan worship offered by Scandinavian place names. Modern scholarship has revealed that the system of mythology presented in Snorri's *Younger,* or *Poetic, Edda,* on which most accounts of Scandinavian paganism are based, represents only the very last stages of this religion as practiced in Norway and Iceland of the Viking age (c.800–c.1050 A.D.). In the Viking age, it was already strongly influenced by Christianity, and pervaded with literary and poetic fantasy. The truth seems to be that Scandinavian mythology was never a unified body of doctrine, but an aggregate of local practices of worship which varied from age to age and from country to country.

Snorri's Mythology.—The system of the *Younger,* or *Prose, Edda* is a complete cosmogony, covering the entire existence of the world. Creation was thought of as the spontaneous result of a union between heat and cold in a chasm called Ginnungagap. The giant Ymir and the cow Audhumla (qq.v.) thus came into being, and through some further links were descended Odin (q.v.) and his brothers. They created the visible world from the body of Ymir, and made the first human couple, Ask (q.v.) and Embla, from two trees. Conflicts quickly arose between men

and giants (*jotnar*), so that the gods had to protect men by creating in the midst of the universe a fortress called Midgard, (q.v., the earth). In the center of it they had set their own dwelling, Asgard, (q.v., for they were called *Aesir*), and outside the wall lay the home of the giants (Jotunheim, a name adopted in modern Norway to designate the wildest mountain region of the country). In Asgard there were 12 chief gods, each with his own palace, but all under the leadership of Odin (Old High German, Wuotan; Old Saxon, Wodan; Anglo-Saxon, Woden; the name occurs in the English Wednesday), father of the gods and ruler of the world. The greatest shrine of the gods was the ash of Yggdrasill (q.v.), which spread its branches over the entire world, and whose roots extended into Asgard, Jotunheim, and Niflheim (q.v.), the latter being the deepest cavern of darkness. This ash tree with its constant process of growth and destruction is a symbol of the universe and its changing fate.

Odin was married to Frigg (from whom we have Friday), and one of his sons was Thor, (q.v.) (cf. Thursday), the god of thunder and the protector of man against the giants, who are clearly associated with the hostile forces of nature. Balder (q.v.), the god of innocence, was another son of Odin and the husband of Nanna (q.v.); he was slain with a dart of mistletoe by the blind god Hoth (Hodr) at the instigation of Loki, and his death was the great tragic climax in the life of the gods. Tyr (q.v.) (cf. Tuesday), the one-handed, was the god of war, while Njorth and his son Frey (q.v.) were gods of fertility who belonged to an originally hostile and older group of gods called the *Vanir*. Another member of this group was Frey's sister, Freya, the goddess of love and beauty. To make life more interesting, the gods had in their midst the evil and mischievous Loki (q.v.) descended from the giants and himself the parent of certain fearful monsters like the Fenris-wolf, the Midgard serpent, and Hel, the female keeper of the dead. Loki was the central figure of innumerable adventures in which he alternately tricked and helped the gods; in the end he suffered for his crimes by being chained in a way reminiscent of the fate of the Greek god, Prometheus. Thor was also involved in a number of adventures, some of them bordering on the burlesque, while Odin's adventures displayed a more subtle cunning. In addition to Frigg and Freya, there were several other goddesses known as the Asynjur.

Odin was the particular protector of warriors, and he sent his Valkyries, (q.v., "the choosers of the slain") to bring him heroes who had died on the battlefield. In his Valhalla, (q.v., "the hall of the slain") they fight and feast until the day of the final world battle when they go forth as Odin's host. This was the famous Ragnarok, (q.v., "doom of the gods," not "twilight" as Wagner understood it), which will be introduced by three years of world war and three years of icy winter. After a veritable Armageddon between the gods and the giants, all will be destroyed by fire, and a new world will rise out of the sea, and a new age will begin when Balder returns from Hel, and "the mighty one who rules all" descends to create a new, just and happy race of men.

Origin.—Snorri himself interpreted the gods as being heroic men who immigrated from Asia and were elevated to divinity. Early German mythographers thought an original monotheism had degenerated into a disgraceful polytheism. Scholars like Max Müller and Viktor Rydberg made much of the idea that the gods were allegories of nature. All of these views have been abandoned in the light of a renewed examination of the evidence. The foundation of a scientific study was laid by the German mythologist, Jakob Grimm (1785–1863, q.v.), in his *Deutsche Mythologie* (1835), although he made the error of assuming that the mythology of the Eddas was of general Germanic origin. Folklorists like Wilhelm Schwartz and Wilhelm Mannhardt distinguished between the "lower" mythology, or universal belief in nature spirits, and the "higher" mythology, which had been developed out of the former by a priestly class. The Dane, Henry Peterson showed that Odin had not always been the chief god, and that in many places, especially in Norway and Iceland, Thor had been the most popular deity. In 1881, the Norwegian philologist, Elseus Sophus Bugge (q.v.) tried to prove that much of Snorri's cosmogony exhibited Christian-classical influences; and later scholars, such as Axel Olrik, Kaarle Krohn, and C. W. von Sydow, have confirmed certain details of this theory. Norwegian scholars like Magnus Olsen and Oluf Rygh have extracted further valuable information concerning actual worship from place names.

It has been shown that the contents of the Eddas is *myth,* which often differs sharply from *faith* and *rite,* and is far more easily influenced by cultural contacts. The Germanic peoples were in constant touch with nations to the south, and learned from them in varying ways and degrees. Like other elements in their culture, the conceptions of their gods underwent constant growth and development. Among the earliest historical knowledge of the Germanic peoples is the fact that primitive fertility practices were associated with a goddess called Nerthus, who Tacitus claimed was the favorite German deity in the first century. But the name is identical with the male Scandinavian Njorth, an older god who plays a fairly modest role in the Eddas. Fertility is further suggested by the name Frigg (which is cognate with the Greek Priapus), as well as Frey and Freya. Another old god is Tyr, who was probably at one time an important sky-god, for he bears the same Indo-European name as the Sanskrit Dyaus, the Greek Zeus, and the Latin Ju-piter; but he is definitely a minor god in the Eddas. These early gods seem to have been partly displaced by Thor, who was very popular in Scandinavia before the birth of Christ. But in the following centuries the worship of Odin (whose name is cognate with the Latin *vates,* or "inspired prophet," and the German *wehen,* "to blow"), who was known as a wind god and leader of the souls of the dead, spread north from the Rhine valley. His association with magic, cunning, and poetry appealed to the viking chieftains, while the common people continued to worship the robust, earthy Thor. Last of all came such a figure as Balder, who can hardly be anyone but Christ: there is not a single place name to indicate that a temple to him had ever been raised, and his own name means simply "lord."

According to Jan de Vries, such elements as the world tree may go back to common Indo-European beliefs, or, as Adolf Schröder main-

tains, they may have been borrowed from the Near East, as parallels can be found in Persian, Iranian, and Greek myths. Similar influences can be traced in the concept of Ragnarok, with its obvious parallels in the Apocalypse and in Iranian religion. Although it seems impossible to disentangle all the details of its development, it is clear that Scandinavian mythology is neither a wholly native nor a wholly borrowed product. Once definite personalities for the gods had developed, it was a short step to filling out their biographies with the most miscellaneous folklore material, and from this aggregate the poets and mythographers created the fascinating structure known as the mythology of the Eddas. Originally a faith, this mythology developed into literature, and became a source of poetic metaphor for the skalds of the Viking Age. It was this sophisticated form of Scandinavian religion which Snorri recorded; the actual rites of worship he either did not know or as a Christian did not care to record.

Bibliography.—The most complete and authoritative recent study is de Vries, Jan, *Altgermanische Religionsgeschichte,* 2 vols. (Berlin 1935–1937); in English, the best is Munch, P. A., and Olsen, Magnus, *Norse Mythology* (New York 1926). The following are also of value: de la Saussaye, P. D. Chantepie, *Religion of the Teutons* (Boston 1902); Craigie, W. A., *Religion of Ancient Scandinavia* (London 1914); Williams, Mary W., *Social Scandinavia in the Viking Age* (New York 1920); Olsen, M., *Farms and Fanes of Ancient Norway* (Cambridge 1928); Olrik, A., *Viking Civilization* (New York 1930); and Shetelig, H., and Falk, H., *Scandinavian Archeology* (Oxford 1937). The sources can be consulted in Brodeur, A. G., *The Prose Edda of Snorri Sturluson* (New York 1916); Bellows, H. A., *The Poetic Edda* (New York 1923); and Hollander, L. M., *The Poetic Edda* (Austin, Texas 1928).

EINAR HAUGEN,
Professor of Scandinavian Languages, University of Wisconsin.

SCANDIUM, in chemistry a rare metallic element discovered by Lars Nilson (1879) in the mineral euxenite; symbol Sc.

SCANNELL, Richard, American Roman Catholic bishop: b. Cloyne, County Cork, Ireland, 12 May 1845; d. 8 Jan. 1916. He was educated at the College of Middleton, Cork, and at All Hallows College, Dublin, at which latter place he was ordained priest, 26 Feb. 1871. He came to the United States the same year and was appointed assistant in Saint Mary's Cathedral, Nashville, Tenn. He served successively at Saint Columba's Church and as pastor of Saint Mary's Cathedral, 1871–85, being administrator of the diocese of Nashville, 1880–83; and as pastor of Saint Joseph's Church, West Nashville, which he organized, 1885–87. On 9 June 1887 he was appointed bishop of the diocese of Concordia, Kan., and was consecrated in Saint Mary's, Nashville, 30 Nov. 1887, by Archbishop Feehan, assisted by Bishops McCloskey and Rademacher. Upon the death of the Rt. Rev. Jas. O'Connor he was transferred 30 Jan. 1891 to the diocese of Omaha.

SCANSORES, skăn-sō'rēz, an obsolete order of birds represented by cuckoos, woodpeckers, parrots, toucans and trogons, and the like, popularly known as that of the "climbing" birds, and distinguished primarily by the fact that the toes are directed two forward and two backward. It was an artificial group, whose members have been scientifically re-classified in the *Coraciiformes* and other groups, and are also known as *Zygodactylæ,* from the arrangement of their toes. Compare NATATORES.

SCAPA FLOW, a body of water about 50 square miles in area, south of Pomona, the largest of the Orkney Islands, and enclosed also by Burra, South Ronaldsay, Flotta, and Hoy. It is one of the safest harbors in the world and, during the World War, 1914–18 and from 1939 was the main base of the British Grand Fleet. Here the German fleet was surrendered to the British in November 1918 only to be scuttled 21 June 1919.

SCAPE-GOAT, a goat which according to the Mosaic law was sent into the wilderness, on the Day of Atonement, bearing the sins of the people (see Lev. xvi, 1–6; Matt. xii, 43; Luke xi, 24). Under later Jewish practice the goat was thrown over a precipice about 12 miles from Jerusalem. Hence the term "scapegoat" is applied to any person who is made to suffer for the wrongdoing of others.

SCAPHOPODA, a class of *Mollusca* of a low type, known as fossils from the Devonian to the present, and surviving in only a small number of forms, typified by the tusk-shells (*Dentalium*). The head is rudimentary, the mantle-edges ventrally concrescent, forming a tube opening before and behind, and covered with a slight-curved shell shaped like an elephant's tusk. The body has its dorsal side toward the concave side of the shell, and is attached to the shell by muscles near the posterior or pointed end. The foot, which can be protruded from the anterior or wider aperture, is rather long, pointed and has sometimes two lateral lobes. All are marine, and some species live in very deep water. Consult Cooke, 'Mollusca' (London and New York 1895).

SCAPOLITE, the name of an important group of rock-forming minerals, including the species meionite, wernerite, mizzonite, marialite. Of these minerals wernerite (q.v.) is by far the commonest. All the species of the group crystallize in the tetragonal system and are hemihedral. Their color is generally white, gray or flesh-red; hardness, 5 to 6.5; specific gravity, 2.57 to 2.74. They are all silicates of aluminum, calcium and sodium; chlorine is also often present. Their composition has been explained by Tschermak by placing meionite at one end of the series with a typical formula of $Ca_4Al_6Si_6O_{25}$ and marialite at the other end with a typical formula of $Na_4Al_3Si_9O_{24}Cl$, and assuming that wernerite and mizzonite are isomorphous combinations of these two compounds in varying proportions. The scapolites are thus an interesting group of minerals similar to the feldspars in their formation of a series of compounds gradually varying in composition, the silica, soda and chlorine increasing as the alumina and lime decrease. Scapolites occur abundantly as primary minerals in Archæan rocks in limestone and gneiss; meionite occurs in the volcanic rocks of Vesuvius, but with this exception, the scapolites occur in eruptive rocks only as secondary minerals, being products of the alteration of feldspars.

SCAPULA. See ANATOMY; OSTEOLOGY; SHOULDER-JOINT.

SCAPULAR, or **SCAPULARY,** an article of attire worn over the shoulders (*scapulæ*) by the inmates of monastic houses. Originally, in the Benedictine Order, it was worn over the regular monastic dress by the brethren when engaged in manual labor, but it is now part of the ordinary habit of the older religious orders, whether of monks or of friars. The word, however, is now commonly used to signify a sort of emblematic scapulary, consisting of two small squares of cloth held together by strings, from which the pieces of cloth are suspended so that one square reaches to the breast and the other to the back at the shoulder blades of the devotee who wears the scapular. There are several different kinds of these scapulars, to the wearing of which are attached sundry obligations and sundry spiritual privileges, such as indulgences, participation in the merits and the prayers of their fellow-members of a scapulary confraternity, etc. These miniature scapulars were brought into use in the 13th century by Saint Simon Stock, an Englishman and general of the Carmelite Order.

SCAR-TATTOOING. See TATTOOING.

SCARABÆIDÆ, skăr-ĭ-bē'ĭ-dē, an exceedingly large family of beetles, including the most gigantic forms, although some of the species, as the chafers, dung-beetles, etc., familiar in the United States and Europe, are of moderate or small size. The terminal segments of the antennæ are composed of flattened plates, producing comb-like clubs. Unlike those of their relatives, the *Lucanidæ,* these plates can be brought closely together so the club appears compact. These plates are relatively larger in the males than in the females. The pronotum, especially in the males, is often ornamented with conspicuous and curiously shaped horns whose purpose is unknown as in the rhinoceros beetle. In structural detail and habits the members of this family differ widely among themselves. Some feed on manure. Certain American species roll together balls of dung wherein they lay their eggs, thus providing food for their grubs. Very many feed on plants, the beetles eating leaves; the larvæ the roots. The grubs are white and fleshy, usually bent into a semi-circle; the large head has powerful mandibles and no ocelli; the body-segments are often transversely wrinkled, and the hindmost segment is often greatly swollen. Some of the adult *Scarabæidæ* are dull black — the dung-beetles for example; while others are of bright metallic hues. The family ranges all over the world, but is most abundant in tropical countries. Several species are serious pests; for instance, May beetles or June bugs the larvæ of which feed on grass roots and when numerous destroy pastures and lawns and rose beetles, the adults of which destroy roses, grapes, etc. Rotation of crops eliminates the pests, and spraying with extra strength, sweetened arsenate of lead as an insecticide is one of the best preventives to control the scourge. A typical example of the group in the sacred beetle of Egypt (see SCARABS), whose carved images are called scarabeids.

SCARABS, representations of the sacred beetle found on Egyptian gems, coins, mummies, obelisks, and works of art. The appearance and rapid multiplication of beetles in the mud on the subsidence of the Nile gave rise to the belief in their spontaneous generation, and they became the symbol of creation and creative power. Their circular shape and the bright, golden tints of their wing-cases suggested the shape and lustre of the sun. Thus they were taken to be one of the forms under which the sun-god appeared. Accordingly, scarabs were cut in stones and employed as seals and amulets, and after being bored through lengthwise were strung like beads, and easily worn on the person. After the commingling of the Egyptian with other races, Gnostics and Christians interpreted the meaning of these gems in accordance with their own religious systems. Those of the most ancient period, such as are found on mummies, are inscribed with the names of the kings held in highest veneration, Thutmosis III, Rameses II, and Amenophis III, and frequently with some hieroglyphic symbol. The larger of them have some short religious or historic inscription on their under side.

SCARAMOUCH, skăr'ą-mowch, term derived from Scaramuccia, a famous Italian buffoon, who acted in England in 1673, and died in Paris in 1694; applied to one of the grotesque characters of the Italian stage, who was dressed entirely in black, wore a mask, and represented the swaggerer and poltroon. In France the scaramouch was used for a greater variety of parts.

SCARBOROUGH, skär'bŭ-rō, **John,** American Protestant Episcopal bishop: b. Castlewellan, Ireland, 25 April 1831; d. Trenton, N. J., 14 March 1914. He came to the United States when very young, was graduated from Trinity College, Hartford, in 1854, from the General Theological Seminary in 1857, and was ordained to the priesthood in 1858. He was assistant rector of Saint Paul's, Troy, in 1857–60, rector of the Church of the Holy Comforter, Poughkeepsie, N. Y., in 1860–67, of Trinity Church, Pittsburgh, Pa., in 1867–75, and in the last-named year was consecrated bishop of New Jersey, where he remained until his death.

SCARBOROUGH, William Sanders, American educator: b. Macon, Ga., 16 Feb. 1852; d. Wilberforce, Ohio, 9 Sept. 1926. He was graduated from Oberlin in 1875, and occupied various chairs at Wilberforce University, of which he was vice-president 1895–1908, and then president. He was of African descent and was actively interested in the education and uplifting of his race. His publications include 'First Lessons in Greek' (1881); 'Our Political Status' (1884); 'Birds of Aristophanes' (1886), etc. He was an authority on Hellenistic and Classical Greek, negro folklore, and philological and archæological subjects.

SCARBOROUGH, England, in the county of York (North Riding), popularly known as «The Queen of English Watering Places,» is on the North Sea, 39 miles northeast of York. The main part of the town is on the south bay, and rises in successive terraces; the new quarters are divided from the older by a deep ravine crossed by two bridges. The modern period of the town dates from the discovery of mineral springs in 1620. The Grand Hotel, on Saint Nicholas Cliff, is one of the largest in England. There is a fine aquarium, a museum

— a Roman Doric rotunda — a mechanics' institute, and the Spa and its grounds are attractive features of the place. There are fine promenades. The People's Park occupies both sides of the valley. Fishing and the manufacture of jet ornaments are the chief occupations. The Romans erected here a number of signal stations as part of the defense of Britain against the Saxons. The remains of one such station was unearthed in 1925. The castle erected about 1136 was held against the Barons by Piers Galveston, and it was twice besieged by the Parliamentary forces. Later it became a fortified barrack. In 1914 it was bombarded with a loss of civilian life by a German squadron. German submarines attacked the place in 1917. Pop. 46,192.

SCARBRO, W. Va., town in Fayette County; 10m. SW. of Fayetteville, on the Chesapeake and Ohio Railroad. The chief industry is coal mining, the famed New River smokeless coal being produced here. The town is situated at an altitude of 1,800 feet and was named for the English town of Scarborough. Pop. 969.

SCARECROW, The. The prolific pen of Percy Mackaye has never turned out a more satisfactory drama than this, called by him «a tragedy of the ludicrous.» It is clearer in its philosophical purpose, more skilful in its dramatic treatment, more direct in its human application than anything he has yet done. When it was given in New York, at the Garrick Theatre, on 17 Jan. 1911, with the excellent support of Frank Reicher, as Ravensbane, and Edmund Breese, as Dickon, a Yankee improvisation of the Prince of Darkness, it met with the cordial recognition it deserved. Were repertory the fashion in the present generation in the American theatre, it would occupy a worthy place among the plays for constant revival.

The inspirational source for 'The Scarecrow' is Nathaniel Hawthorne's 'Feathertop,' a tale included in his 'Mosses from an Old Manse'; Mr. Mackaye acknowledges his dependence on the story for the main ideas of his plot. But he writes an introduction to the printed play, showing the main details in which he and Hawthorne differ. These may be summed up briefly: Hawthorne's Scarecrow «is the imaginative epitome or symbol of human charlatanism,» the satire being aimed against fashionable society. Mr. Mackaye stretches his philosophy to wider application. His Scarecrow, Ravensbane, is the «emblem of human bathos.» Are we not all more or less human scarecrows, composed of rubbish, out of which we have to hew our own salvation? When Dickon and Goody Rickby construct a scarecrow, and breathe into him, by their devilish magic, the breath of life, symbolized by the glow of a pipe, which keeps Ravensbane alive, they do so in order to wreak vengeance on the old justice, Gilead Morton. But they give no thought to the tragedy which might befall a scarecrow thus thrust upon the world and subject to human experience. They do not realize that when, at the end, in love with the justice's niece, Ravensbane looks into the magic mirror, which reveals people as they really are, he will see himself as a scarecrow, and the tragedy of the ludicrous, so entertaining to the onlooker, will fall heavily on his own poor pumpkin head.

«What absurdity is our highest consummation!» writes Mr. Mackaye; «Yet the sense of our highest deficiency is, after all, our salvation. There is one reality which is a basic hope for the realization of those dreams. This sense is human sympathy, which is, it would seem, a more searching critic of human frailty than satire. It is the growth of this sense which dowers with dignity and reality the hollowest and most ludicious of mankind, and becomes in such a fundamental grace of character.»

Where Hawthorne ends, therefore, so Mackaye claims, his play begins; where Hawthorne's shafts hit charlatanism, he mingles human sympathy with irony, and there is for Ravensbane, the scarecrow, the same feeling of pity that one feels, now and again, for Don Quixote. In his object the dramatist succeeds well. With the result that 'The Scarecrow' may be accounted a good drama, admirably fulfilling its purpose, and admirably reflecting New England temperament of the early witchcraft days.

MONTROSE J. MOSES.

SCAREY CREEK, Engagement at. On 2 July 1861 General McClellan, then preparing to advance from Buckhannon against the Confederate forces under General Garnett at Rich Mountain, ordered General Cox to move with one brigade from Camp Dennison, Ohio, cross the Ohio River at Gallipolis, and operate in the Kanawha Valley, the object of the movement being to secure McClellan's right flank and to prevent General Wise from reinforcing Garnett at Rich Mountain. With three regiments Cox arrived at Gallipolis, where he was joined by another regiment, and on the 10th crossed the river to Point Pleasant, where he received orders from McClellan to drive Wise from the Kanawha Valley. Cox went up the Great Kanawha on steamboats, and at the mouth of Scarey Creek, on the south side of the river, found his passage disputed by a force of 200 men, with two guns, under command of Colonel Patton. It was necessary to dislodge Patton, whose two guns commanded the river. A small body of Cox's command had reconnoitered the position, and awaited the arrival of Cox's main body, which came up on the 16th. Cox landed on the north side of the river, and on the 17th Colonel Lowe, with the 12th Ohio, two companies of the 21st, and some cavalry, in all 1,020 men and two guns, was landed on the south side of the river and advanced upon Patton, reaching the bank of the creek about 3 P.M. The two guns were put in position and the cavalry advanced, but were speedily driven back by the Confederate guns. The artillery now opened on both sides and, after some sharp firing, Patton's men were seized with a panic; but reinforcements coming up, they were rallied, and the Confederates advanced and took position along the bank of the creek across which there was quite a severe contest. A small Union force was sent across the creek to turn the Confederate left and seize their guns; but, not waiting for this movement to develop, the main body charged across the creek and drove the Confederates up the hillside, back upon their guns, and another panic ensued. But more reinforcements coming up, the Confederates rallied and poured such a telling fire into the advancing Union line that it fell back in

disorder, leaving dead and wounded on the field, recrossed the creek, and continued the retreat. The Union loss was two officers and 12 men killed and 47 men wounded; the Confederate loss one officer and four men killed and nine wounded.

SCARIDAE, a large family of fishes, represented by the parrot fishes, which occur in all warm seas, lingering about coral reefs and weedy rocks. Few species are of any value as game or for food. See also ICHTHYOLOGY.

SCARLATINA. See SCARLET FEVER.

SCARLATTI, skär-läa'tē, **Alessandro,** Italian composer: b. Trapani, Sicily, 1659; d. Naples, Italy, Oct. 24, 1725. Appointed maestro di capella by Queen Christina of Sweden, he wrote his first opera for performance in her palace. He produced his first oratorio *I Dolori di Maria sempre Vergine,* in 1693, and was then appointed maestro di capella to the viceroy at Naples. He held the position of chapelmaster at Santa Maria Maggiore, Rome, 1707–1709, and then returned to Naples. Scarlatti was possessed of great fertility of imagination. In method he opposed the enemies of the counterpoint, being considered the greatest contrapuntist of his age, and the inventor of accompanied recitative. His compositions, few of which have been published, included 115 operas, 200 masses, 9 oratorios, 500 cantatas, and miscellaneous minor pieces. Three of his operas, *Geroue; Il Flavio Cuniberto;* and *La Teodora Augusta,* preserved in the original manuscripts, are at Christ Church, Oxford, England, and another is in the British Museum.

SCARLET FEVER (SCARLATINA). An acute contagious disease commonly affecting children in the first decade of life, characterized by inflammation of the pharynx, a punctate erythematous rash, and later, by desquamation of the skin. It is caused by a variety of hemolytic streptococcus, specifically, the *streptococcus scarlatinae.* It is of interest to those who study medical history that the disease received its name, *scarlatina,* from Thomas Sydenham (1624–1689) who described it clearly (1689), differentiating it from measles. Since Sydenham's time scarlet fever has swept over the world in severe epidemics, and only in the present century has it ceased to be a serious factor in mortality and in the complication of lifelong deafness that, in former days, so often followed in its wake.

The disease is spread in a number of ways: by direct contact with one who has the disease, perhaps in a mild form; by fomites; and by the milk of cows whose udders are infected by the streptococcus. It is believed that persons can transmit the disease for several weeks after infection. This likelihood is responsible for enforcement of a prolonged quarantine. The exact manner in which the infection is introduced is not known positively, but the disease is not transmitted through skin shedding or "peeling," as once was supposed. Scarlet fever is seen most often in the fall and winter months, and its incidence corresponds roughly with the school season. Children who are not immunized against it are easily infected. In tropical countries it is seldom seen. The incubation stage is variable, from three to eight days being the usual limits. Onset is extremely sudden, with vomiting, chills, headache, loss of appetite, and sore throat. The throat soon becomes excessively painful and swallowing is difficult. Vomiting may persist for some time. The fever ranges from 102° to 105°, with a rapid bounding pulse. Examination of the throat will show intense redness, the inflammation extending over the pharynx and palate. Small bright red areas often appear against the darker background of the mucous membrane of the throat, which are characteristic symptoms. The tongue is heavily furred, having a creamy look, the edge presenting an appearance known as white strawberry tongue. Within a few days the whitish aspect disappears and the whole tongue then resembles a bright red strawberry. This is said to be diagnostic of the disease. In from 24 to 48 hours, a rash is observed on the upper parts of the trunk which spreads to the back and, finally, covers the entire body with the exception of the face. The skin rash is a light red, with deeper red spots or papules. Not all scarlet fever rashes are alike in appearance and sometimes the diagnosis cannot be made by that means alone. The eruption fades gradually, disappearing in about a week, as the temperature reaches normal. Peeling of the skin (desquamation) begins with the disappearance of the eruption and is completed in about four weeks. Many cases of scarlet fever do not present the usual symptoms or follow the same course. In severe cases especially, atypical forms will be encountered, but most of these, once known as malignant scarlet fever, are seldom seen today. Severe attacks show exaggeration of all the symptoms, especially the sore throat. The fever may be dangerously high, and delirium is common. In some there is marked edema of the throat, sometimes accompanied by ulceration and a foul discharge. Due to the toxemia, prostration is extreme. Mild cases, on the other hand, may escape notice and remain undiagnosed.

The complications of scarlet fever are numerous. Those seen most frequently are middle-ear disease, sometimes resulting in mastoid inflammation from extension, local suppuration of the throat and neck, acute nephritis, general sepsis with all its ramifications, and arthritis. The last involves several joints usually and unless the purulent variety is manifest, is recovered from entirely. The commonest cause of death is from septicemia, in which the peritoneum, the lung, the pleural cavity, the joints, and the meninges of the brain may be involved. Ordinarily, scarlet fever is not difficult of diagnosis. In the early stages, before desquamation begins, mild cases may not be apparent unless the possibility of the disease being present is kept in mind. Certain drugs—and their name is legion—may produce a rash similar to that of scarlet fever, but sore throat is absent. (A few of the many drugs which may be mentioned in this connection are boracic acid, salicylic acid, antipyrin, arsenic, and belladonna.) The eruption in measles may at times be confused with that of scarlet fever, but its early occurrence on the head and face differentiates it, while desquamation in measles is of a branlike character instead of having the flaky appearance of the shedding in scarlet fever. In the latter there is a leucocytosis while in measles there is a decrease in the white blood cells (leucopenia). The Dick test, the injection of a skin test dose (0.2 cc. of a 1 to 1000 dilution of scarlet fever toxin) into the skin of the forearm is

positive if given early, as it is in healthy non-immunes. A positive indication is the formation, in the first 24 hours, of a red area at the site of the injection. The Schultz-Charlton test, or phenomenon, is of some value but is not always to be relied on. Convalescent serum (0.1 cc.) is injected into a red area in the skin during the stage of the rash. If an area of whitening (blanching) is seen at the site, the rash is due to scarlet fever.

In the treatment of scarlet fever, health laws in various communities require, as a rule, isolation and quarantine for from four to six weeks, or even longer if active organisms remain in the tissues. Those who have never had the disease are also quarantined, if they have been exposed, for the maximum incubation period of eight days. Under prophylactic treatment, immunization is recommended usually, for those who have not had the disease or who give a positive Dick test. For immunization, five weekly subcutaneous injections of ascending doses of scarlet fever toxin are given as recommended by the Scarlet Fever Commission. Immunity is acquired in about three weeks after completion of the course. Severe systemic reactions may occur from injection of the toxin, especially in very young children.

Specific therapy includes the following measures: the use of scarlet fever antitoxin in a single dose of from 15,000 to 40,000 units given intramuscularly or, in urgent cases, intravenously; the use of convalescent serum obtained from a single person or, preferably, from a considerable number of individuals, in a single dose of 40 to 100 cc.; the administration of sulfonamides, especially sulfadiazine, in doses up to 650 milligrams, several times a day orally, or intravenously (in which case the sodium sulfadiazine is chosen), until the temperature becomes normal. Convalescent serum is said to be fully as effective as antitoxin without the former's tendency to cause a severe reaction. Sulfonamides do not affect the toxic stage and do not lower the temperature nor aid the sore throat. They do influence the mortality and the occurrence of complications, probably decreasing their severity. In spite of the wide acceptance of the Dick test, as claimed by its proponents who believe that 90 per cent of those receiving proper immunization are protected for life, there are many who question the value of present methods of Dick testing and immunizing. They maintain that the toxin does not represent all strains of streptococci present in scarlet fever, that the test is not always reliable, that it is not possible to achieve complete active immunity against the streptococcus, that the test is difficult to interpret, that attempted immunization causes the rash to disappear and thus a valuable diagnostic aid is lost and that immunity is transient and practically never permanent.

Treatment other than specific consists of rest in bed with careful nursing, an easily digested diet for several weeks, a generous fluid intake, care of the bowels and skin, local treatment of the throat and nasal passages, and a careful watch for complications, especially nephritis and middle-ear disease. (The question of complete isolation of the nurse, with separate living quarters, and so forth, is still debated. Sterilization of dishes used in the sick room and burning of all garbage is insisted upon in many quarters.) The prognosis is not always to be determined in the individual case, since mortality may vary from 3 to 40 per cent according to the particular epidemic. In general, mortality is in inverse ratio to the age of the patient, younger children succumbing much more easily than those of eight or ten years. An attack of scarlet fever confers immunity for life. Consult Yater, Wallace M., *Fundamentals of Internal Medicine,* 2nd ed. (New York 1942).

HAROLD W. JONES, M.D.

SCARLET IBIS. See IBIS.

SCARLET LETTER, the first and by general consent the greatest of Nathaniel Hawthorne's four chief romances, was originally planned as a short tale, and was expanded to its present proportions on the urgent advice of the author's friend and publisher, James T. Fields. When, with the change of administration in 1849, Hawthorne was removed from the surveyorship of customs at Salem, he undertook a collection of short pieces that might have borne to the custom-house, where he had worked, the same relation that his preceding collection had borne to the Old Manse, where he had lived. An introductory sketch, *The Custom-House,* written for this collection, is always prefixed to *The Scarlet Letter,* though it has no real connection with the romance, and though it contains some unfortunate personalities which show the writer's ill-temper over the loss of his position. The account in this sketch of the finding of a moth-eaten embroidered "A" and a manuscript in the upper rooms of the custom-house is of course fanciful. Years before, in the tale of *Endicott and the Red Cross,* Hawthorne had made incidental mention of a woman who was forced to wear a scarlet "A" in token of her guilt, and the thought of this punishment, or rather of its effect on the wearer, seems to have remained with him until it resulted in the creation of Hester Prynne. *The Scarlet Letter* was published in the spring of 1850, and instantly won for the author a recognition that had been denied to the delicate and finished shorter tales of his earlier collections. Its reputation in America has increased rather than diminished with time, and it has been warmly praised in England. In other countries it is less known, perhaps partly because many of its effects are too subtle for translation, partly because the peculiar New England quality is not readily appreciated by those of another race. *The Scarlet Letter* is in every way typical of Hawthorne. The background is colonial New England, and the theme is the effect of a great sin on the four persons most concerned—Hester Prynne, who wears the scarlet letter, her paramour, the wronged husband, and the child who is the offspring of illicit love. When the tale opens, the sin is a thing of the past, and the judgment of the law has been imposed. The author passed by the story of love, temptation, yielding, and discovery, and beginning where another novelist might have ended he traced the moral and spiritual tragedy which followed. Even in the handling of this material he made no use of the ordinary devices of the storyteller. Thus, the identity of the guilty man, which might have been so treated as to arouse curiosity and then revealed with startling effect, is allowed to transpire quietly. The chief contrast is between Hester, who suffers

openly, and her partner in guilt, who maintains his honorable position in the community unsuspected; and the lesson which is most likely to be drawn is that of the virtue of open expiation, and the evil of concealment, even where there seem to exist the strongest arguments against confession. In the author's own words, «Be true! Be true! Be true! Show freely to the world, if not your worst, yet some trait whereby the worst may be inferred!» A secondary moral, the deadening effect of a secret and long-continued plotting for revenge, as seen in the husband, Chillingworth, is almost too obvious. Yet 'The Scarlet Letter,' while it is sure to stimulate thought, is not in any sense a preachy book. The reference in the conclusion to Hester's belief in «a new truth» which should «establish the whole relation between man and woman on a surer ground of mutual happiness,» is somewhat perplexing, but has probably been taken by radical social reformers more seriously than the author intended. Throughout the book the thought of the scarlet letter, both as a material object and as a symbol, is everywhere present, and is woven into the tale with even too great ingenuity. It is personified in the child, Pearl; it seems to imaginative observers to be flashed in the heavens by the track of meteors; and as we are led to believe, it was burned in penance on the breast of the guilty man. The background, the characters, like the demented witch-sister of the governor, the incidents, and the motive unite to sustain throughout the romance a uniform tone — sombre, tragic, unbroken from first to last by a trace of humor, and still neither morbid nor repellant. It would have been a great achievement to tell such a story for the select few who are fond of subtle psychological analysis; it is marvelous that Hawthorne made a tale, in which nothing outward happens, appeal to the mass of readers who are accustomed to demand constant action.

WILLIAM B. CAIRNS.

SCARLET TANAGER. See TANAGER.

SCARLETT, SIR **James Yorke,** English soldier: b. 1799; d. December, 1871. He was educated at Eton and Cambridge, entered the army, and in 1854 was sent to the Crimea in command of the heavy brigade. On the 25th of October he led the brigade in its famous charge at Balaclava, and later in the day it brought out of action the remnants of the light brigade after its even more famous charge. In both of these actions Scarlett took a prominent part in the hand-to-hand conflict. For these services he was promoted to the rank of major-general, on 12 December following, and upon the retirement of Lord Lucan took command of the entire cavalry forces in Crimea. In July 1855 he was created a K.C.B. He commanded the camp at Aldershot 1865–70, and retired from active service in the last-named year.

SCARP. See FAULT; also ESCARPMENT.

SCARPA, skär'pä, **Antonio,** Italian anatomist: b. Friuli, Italy, 13 June 1747; d. Pavia, Italy, 31 Oct. 1832. He studied medicine at Padua, in 1772 was appointed professor of anatomy at Modena, and published in that year his first work on the anatomy of the ear, 'Anatomicæ Observationes de Structura Fenestræ rotundæ Auris.' In 1783 he resigned this chair to accept a similar one at Pavia, where he published his great work, 'Anatomicæ Disquisitiones de Auditu, etc.' (1789). At the time of the revolution in Italy he was deprived of his professorship in the university on account of refusal to take the oath required by the Cisalpine republic. He now published his celebrated work on 'Aneurisms' (1804). When Napoleon, after his coronation as king of Italy, arrived at Pavia (1805), and received the officers of the university, he inquired after Scarpa. He was informed that he had long ceased to be a member of the university, and was told the reason. «What,» said Napoleon, «have political opinions to do here? Scarpa is an honor to Pavia and to any dominions. Let him be honorably restored.» Scarpa was the author of several other surgical works besides those already mentioned. Most of his works have been translated into English and French.

SCARPANTO (Carpathos), one of the Aegean Isles formerly belonging to Turkey, and since 1912 under the sovereignty of Italy. It is 27 miles long by six miles wide, is rocky and mountainous, and has four harbors, two on the east, one on the north and one on the southwest side, known respectively as Port Pernesi and Port Avdemo, Port Skomaco and Port Grato. There are indications pointing to a former dense population, as judged from the numerous ruins of towns. Pop. 11,500.

SCARRON, skä-rôṅ, **Paul,** French author and playwright: b. Paris, France, 6 July 1610; d. there, 6 Oct. 1660. Refusing to take orders he led a wild life in Paris and in Rome, to which city he went in 1634. Shortly after his return to Paris in 1637 he was stricken with an illness which left him a paralytic for the rest of his life. His mind was not affected, however, and he made his livelihood by literature. At one time he was the pensioner of the queen, but losing his pension through the influence of Cardinal Mazarin, he then wrote in revenge his satirical 'Mazarinade' (1649), one of his best-known works. He married in 1652 the young and beautiful Francine d'Aubigne, afterward Mme. de Maintenon. Both before and after this event, which Scarron survived eight years, his house was the centre of a brilliant literary society. The most famous of Scarron's writings in his own time is said to have been his 'Virgile Travesti' (1648–53), but modern critics prefer his 'Roman Comique' (1651). There have been many editions of his works; the best are those published in Amsterdam (10 vols., 1737) and reprinted at Paris (7 vols., 1786).

SCARZONERA, a genus of composite plants with numerous species, chiefly indigenous to the Mediterranean regions. The flowers are yellow or rarely rose-colored, having many series of involucral bracts, plumose and unequal pappus, and achenes without a beak and generally wingless. *S. hispanica,* sometimes known as viper's grass, has long been cultivated for its tapering, fleshy, edible roots, the dark-brown skins of which have caused it to be called black salsify. The leaves are long and lanceolate with waving edges. Other species are also cultivated for their roots.

SCAUP, skâp, or **BLACKHEAD DUCK,** a duck (*Aythya marila*), of the same genus as the redhead (q.v.), which it closely resembles in form but from which the green-glossed black

head of the male and the white face of the female distinguish it. It is a very abundant duck about the shores of the North Atlantic, frequenting the sounds, bays and estuaries of the United States to Central America in winter and in the spring passing northward and inland to breed. On the coasts of the New England and Middle States the scaup is most abundant during the fall migration, occurring in flocks which feed chiefly upon small mussels and other marine animals, especially mollusks, secured by diving.

A closely related species is the lesser scaup duck (*A. affinus*), which is almost an exact smaller counterpart of the blackhead, except that the head of the male is glossed with purple instead of green and the length is about 16 instead of 18 inches. This species regularly consorts with the larger scaup and is altogether similar in distribution and habits. Both species are shot in large numbers by sportsmen and market gunners and regularly sold in the markets, but the flesh is rather coarse and strong-flavored.

SCELIDOTHERIUM. See MEGATHERIUM.

SCELOPORUS, sē-lŏp'ō-rŭs, a genus of lizards of the family *Iguanidæ,* to which the Florida chameleon (*Anolis*) and the horned toads (*Phrynosoma*) also belong. Among its kindred, this genus is distinguished by its imbricated keeled scales, the absence of a dorsal crest, of gular folds or a gular sac and of head-spines. The tympanum or ear-drum is exposed between the small scales of the side of the head; the tongue is fleshy and shaped somewhat like an arrowhead; teeth are confined to the jaws and have trilobate summits. Femoral pores, the secretion of which assists the sexes in mating, are well developed. Between 30 and 40 species of this genus are known, all of them American and most of them confined to Central America, Mexico and the southwestern United States. In this region these lizards are exceedingly abundant and are everywhere conspicuous objects. They are chiefly terrestrial, but many of the species also live upon stone walls or fences or run up tree trunks when alarmed. Their food consists of insects, which they seize with the greatest agility. In temperate regions they hibernate in cold weather. The males are generally ornamented with bright colors on the under parts which may be considered to be secondary sexual characters. The eggs, which have a parchment-like shell hardened with lime, are usually retained in the oviducts until the young are partly or wholly developed; when deposited, holes in the ground, decayed stumps, etc., are utilized for their concealment. As in many other lizards, the tail is easily broken along an unossified plate across the body of the vertebræ, after which it regenerates, but always imperfectly. The only eastern species is the common swift or fence-lizard (*S. undulatus*). Consult Cope, 'The Crocodilians, Lizards and Snakes of North America' (United States National Museum, Washington 1900).

SCENES OF BOHEMIAN LIFE, The, by Henri Murger (1822–61), though published at the beginning of his literary career (they began to appear in the periodical press in 1847) mark the highest point in his achievement. His poetry (he always believed himself a poet) has not stood the test of time, and his later novels are outranked by their predecessor. This suffices, however, to give him his place which is larger in the affectionate remembrance of his compatriots than in French literary history, for his success was due to the peculiar optimism and buoyancy of his temperament rather than to any special artistic quality. This temperament allowed him to regard his own difficult and harassed life as a subject for comedy and high-spirited rejoicing. His famous work frequently reproduces scenes and incidents in his own experience. The son of a Paris janitor and tailor, he was driven from home as a lad and in his effort to win recognition as a poet was reduced to a condition of starvation which resulted in impairing his vitality and frequently brought him into the wards of Paris hospitals. To support himself he was at intervals, like his hero Rodolphe, reduced to uncongenial and often unpaid tasks on cheap ephemeral trade journals like the *Scarf of Iris* or *Beaver* (*Le Castor*) of the *Scenes.* On one ever memorable occasion he, however, received for past and future services 500 francs, which provides one of the well-known incidents of his story. The indulgent ever-smiling young *Bohémiennes,* like Mimi and Phemie and the rich young lady cousins, never if ever appeared in the doorway of his garret where he toiled unremittingly for success. It is for this reason that it is no true picture either of his own struggle or of the hard-working and serious life of the Latin Quarter of his time, which, though it had its rare gala days of festival and high spirits, had also its long months and years of unrequited toil that often ended in final poverty and failure. For this reason those who know «Bohemia» best refuse to recognize Murger as its portrayer. A truer picture is to be found in the biographies of Balzac or Zola or Daudet, who passed through its toil and trials before or after this time. It should also be remembered in this connection that of the hundreds of talented young men who struggled with them only a very small percentage won lasting recognition or any financial reward. Murger was, therefore, not in any sense a realist but a delightful humorist and idealist who created certain exaggerated but ever fresh and amusing types and who made a life of toil against heavy odds, relieved by the joys of youthful comradeship and kindred aims, appear as one long and uninterrupted holiday. This exaggeration of type is the reason why his heroes and heroines with but little change make the strikingly successful characters of the light opera by Puccini based upon his work. It was Bohemia as he would have wished it, but as it never was for him or his serious brothers in the fellowship of art. See BOHÊME, LA.

CHRISTIAN GAUSS.

SCEPTICISM, in its widest meaning, is a state of doubt or suspense of judgment. It is often used in connection with religious belief, and here indicates doubt or disbelief of authorized doctrines. The word scepticism has a specific meaning, however, which is implied in its more general uses, and in this meaning it has a philosophical reference and relates to the problem of knowledge. Thus used, scepticism signifies systematic doubt or entire disbelief in

the ability of the human mind to attain knowledge of positive or objective truth. Such scepticism has been of frequent occurrence in the history of thought from antiquity to the present time. It has received systematic expression from several noted thinkers who supported their conclusions by explicit arguments. The grounds of systematic scepticism are many and cannot be given in full detail. Its fundamental basis in theory is usually found in the assumption that knowledge arises from a succession of particular sensations which are (1) subjective modifications, and (2) detached and transitory mental states. As subjective modifications, these sensations are the product of the sense-organs of the individual. Their nature depends upon the structure of the particular sense-organ, which varies with each individual, and also upon the bodily condition of the individual which varies from moment to moment. Hence these sensations, being relative to individual structures and conditions, have only a subjective value, and can yield no truth that is objective and necessary for all. As detached and transitory mental states, these sensations can furnish no criterion of truth beyond the single sensation. Because detached and particular, such a single sensation can justify no conclusion of universal validity. Because itself transitory, such a single sensation can reveal nothing of a permanent and abiding reality. Beside these theoretical considerations, many practical reasons have been urged to support scepticism, such as the difference of opinion and belief among different peoples upon most vital matters of life and morals. In antiquity the first important exponents of scepticism were the Sophists of Greece. Of this school Protagoras held that all truth was relative, since all sensations were subjective. At a later period in Greek thought, a systematic scepticism was developed by Pyrrho of Elis and elaborated by his school. According to the Pyrrhonic scepticism, the real nature of things is entirely unknown to us because of the subjectivity of our impressions and opinions; and, consequently, our proper attitude is one of suspense in judgment and apathy in conduct. The foremost representative of scepticism in modern times is David Hume. He maintained that "all knowledge resolves itself into probability"; for, being based upon particular impressions, it can reveal nothing of permanent or objective reality beyond the succession of sensations. In estimating the importance of scepticism in the history of thought, one must distinguish between scepticism as (1) a provisional stage and (2) a final conclusion of thought. As a provisional stage, scepticism has discharge an important office in the development of thought. In the life of both individual and race, periods of scepticism are useful in disposing of traditional beliefs which lack adequate foundation, and so in preparing the way for better-established conclusions. Thus with Descartes a stage of doubt was preliminary to his positive thought, and likewise the scepticism of Hume was preliminary to the constructive philosophy of Kant and his successors. As a final conclusion scepticism has never been permanently satisfactory, because the inherent demand of the human mind is for positive truth.

Consult Plato, 'Protagoras'; Zeller 'Stoics, Epicureans, and Sceptics' (tr. London 1892); Hume, 'Treatise of Human Nature'; Owen, 'Evenings with Sceptics.'

SCEPTRE, originally a staff, the emblem of sovereign power. The baton, or short sceptre, has always remained a sign of distinction. In the Greek assemblies a person who wished to speak received a sceptre from the herald; and the judges also bore it while in the exercise of their authority. Kings swore by the sceptre. By degrees it became the emblem of power alone. Through the Roman emperors it passed to the western monarchs.

SCHAAFFHAUSEN'SCHER, A., (shâf-hou'zĕn-shĕr bănk-fĕr-īné,) **BANKVEREIN.** The A. Schaaffhausen'scher Bankverein of Cologne was founded in 1848 as a reorganization of the firm of Abraham Schaafhausen (seriously affected by the troubles of the same year), with a capital of 5,187,000 thalers (about 15,600,000 marks), of which the initial issue was 3,199,800 thalers. In 1914 it was absorbed by the Disconto-Gesellschaft (q.v.), retaining its name and clientele under the management of W. L. Deichmann, Gustav Mevissen and Victor Wendelstadt, men of caution and experience, the institution began its activities in the fostering of important industrial enterprises. Its purpose may be inferred from an excerpt from the annual report for 1852 — "the function of a great banking institution is not so much to start new branches of industry through extensive participation, as to induce the capitalists of the country, by recommendations based on exhaustive investigations, to turn idle capital toward such enterprises, which, when properly launched, in response to existing requirements, and offering the guarantee of expert management, bid fair to yield reasonable profits." Industrial in purpose, current account business was secondary, and deposits were received only on condition of three, six and 12 months' notice being given for their withdrawal, and then only at a low rate of interest. The close identification from the first with the prosperous and flourishing Rhenish-Westphalian industry, and the strict adherence to its original purpose, lent strength to the Bankverein to weather the financial crisis of 1857 without the necessity of canceling any of its outstanding credits — a strong factor in extending its influence during succeeding years. One after another it nurtured industrial enterprises within its banking zone, each becoming an added source of strength for the Bankverein. In 1891 a branch was opened at Berlin — a branch in fact as well as name — the parent institution remaining the only one of the five German "great" banks having its headquarters outside of Berlin. In 1908 the number of branches was 10, with one silent partnership, or "Commandite" and 15 deposit offices. Six subsidiary banking companies were founded wholly or in part by the Bankverein (largely in co-operation with the Dresdner bank), giving foreign banking and exchange facilities, a small incident in the general scheme of the Bankverein. Four German banks with 13 branches were absorbed wholly and another jointly with the Dresdner bank. In addition, through ownership of shares, it maintained community of interest relations with three important banks, having 21

branches and numerous agencies, deposit offices and subsidiary connections. Most important, however, was the community of interest, mutual in terms, between the Dresdner bank and the Bankverein, beginning 1 Jan. 1904. Representation was maintained on the boards of 94 other industrial and financial institutions. The capital of the Bankverein was 145,000,000 marks; and 34,157,125 marks surplus. The total capital power of the A. Schaaffhausen'scher Bankverein group was 278,538,001 marks, of which 231,000,000 marks constituted the capital, and 47,538,001 marks the surplus. Consult Riesser, Dr. J. (1909), 'Die deutsche Grossbanken und ihre Konzentration'; 'Germany's Economic Forces' (1913); 'Report on Co-operation in American Export Trade' (Washington 1916).

SCHADOW, shä'dō, **Johann Gottfried,** German sculptor: b. Berlin, 20 May 1764; d. there, 27 Jan. 1850. After many vain struggles to become an artist, he was admitted to the studio of the sculptor Tassaert and thus at length succeeded in devoting himself to his chosen art. Soon afterward he ran off with his sweetheart to Vienna, and there married her; and then, at the expense of his father-in-law, went to Italy, where he wrought with unwearied diligence from 1785 to 1787 in the museum of the Vatican and of the Capitol, winning a prize by his group 'Perseus and Andromeda.' In 1788 he obtained the position in Berlin which had become vacant by the death of his teacher Tassaert. His first great work was the monument erected in the Church of Saint Dorothea, Berlin, to the memory of the margrave, natural son of Friedrich Wilhelm II. This was followed by the colossal statue of Ziethen in hussar uniform; the statue of Frederick the Great in Stettin; of Leopold of Dessau in Berlin; of Blücher in Rostock; the Tauenzien monument in Breslau; Luther's in Wittenberg, etc. The four-horse chariot of Victory, over the new Brandenburg Gate of Berlin, was modeled by Schadow. Schadow executed many busts of his eminent countrymen and numerous relievos and statuettes. In 1788 he was made rector and in 1822 director of the Academy of Art in Berlin, a position which he retained until his death. He was one of the first of the modern sculptors who dared to withstand the fantastic mannerism of the 18th century for which he substituted a powerful representation of character based on a study of the antique. His most eminent pupil in this respect is Rauch; among his other pupils may be named Dannecker, Tieck and Zauner. His chief literary works are 'Wittenberg Denkmäler der Bildnerei, Baukunst und Malerei, mit historischen und artistischen Erläuterungen' (1825); 'Polyklet, oder von den Massen des Menschen nach dem Geschlechte und Alter' (1834); 'National-physiognomien, oder Beobachtungen über den Unterschied der Gesichtszüge und die äussere Gestaltung des menschlichen Kopfs, in Umrissen bildlich dargestellt' (1835); 'Kunstwerke und Kunstansichten' (1849). Consult Dobbert, 'Gottfried Schadow' (1887).

SCHADOW, Rudolph, son of the preceding, German sculptor: b. Rome, 9 July 1786; d. there, 31 Jan. 1822. He was trained as sculptor by his father and his principal works are 'Spinning Girl'; 'Achiles and Penthesilea'; 'John Baptist' and 'Virgin and Child.'

SCHADOW-GODENHAUS, gō'děn-hows, **Friedrich Wilhelm,** younger brother of the preceding, German painter: b. Berlin, 6 Sept. 1789; d. Düsseldorf, 19 March 1862. He received his first lessons in drawing from his father, then turned to painting and became the pupil of Weitsch. He served in the war between 1806 and 1807 and three years later resumed his artistic studies in Rome, where Cornelius, Overbeck, Veit and others had founded the new school of the Nazarenes (q.v.). He joined their company and from that time made the Italian masters his models, while the favorite subjects of his pencil were biblical, or selected from the mystical and allegorical wonders of mediæval tradition. As in the case of Overbeck, his devotion to this latter field of human imagination led him to become a member of the Roman Catholic Church. He painted 'Heaven's Queen' for Madame von Humboldt and a 'Holy Family' for the Crown Prince Ludwig of Bavaria. The best work he did at Rome is seen in the frescoes for the Casa Bartholdy; 'Jacob with Joseph's Bloody Coat'; 'Joseph in Prison' (both in the Berlin National Gallery). In 1819 he was called to Berlin as professor of the Art Academy there. During his incumbency he painted the 'Bacchanalian Procession' on the proscenium of New Theatre; many portraits; the 'Visit of the Wise Men' in the Garrison Church at Potsdam and another altar-piece for the church at Schulpforta. One of his finest pictures is 'Freeborn Poetry,' a lovely winged maiden rising from earth to heaven. In 1826 he was made director of the Academy in Düsseldorf and with a circle of enthusiastic pupils became the founder of the Düsseldorf school. He retained this connection until 1859, when age and failing sight led him to retire. Among his religious paintings are 'Christ on the Mount of Olives'; 'Christ at Emmaus'; 'The Dead Body of Christ watched over by his Mother surrounded by Angels' (1836). His health drove him to seek a change in the warmer climate of Italy (1840), and at Rome he painted 'Earthly and Heavenly Love'; 'Piety and Vanity in their Relationship with Religion,' the last appearing under the form of the Saviour, and 'Heaven, Purgatory, Hell' after Dante. As an author he wrote 'The Influence of Christianity on the Painter's Art' (1843). His paintings are mostly found in Düsseldorf and Berlin, but one of his best works, the 'Wise and Foolish Virgins,' is in the Museum at Frankfort-on-the-Main. He was perhaps more successful as a teacher and demonstrator than as a creative artist, but he had a very distinct, even though one-sided influence, upon the religious art of Germany. He gave a new and vigorous impulse to the oil painting of his day without resorting to that pre-Raphaelite realism which sometimes lent to the canvases of Cornelius a certain crudeness bordering on the grotesque. Consult Hübner, 'Schadow-Godenhaus und seine Schule' (1869).

SCHAEBERLE, John Martin, American astronomer: b. Würtemberg, Germany, 10 Jan. 1853; d. Ann Arbor, Mich., 19 Sept. 1924. He was brought to Ann Arbor, Mich., in his infancy, and was graduated from the University of Michi-

gan in 1876 as a civil engineer. He devoted himself to the study of astronomy, to which department of knowledge he made valuable contributions. From 1876 to 1888 he taught astronomy in the University of Michigan, and was then called to the Lick Observatory at Mount Hamilton, Calif., where he made several important astronomical investigations. He had charge of the expedition to witness the eclipse at Cayenne in 1889, and of those for the same purpose to Chile in 1893, and to Japan in 1896. During his later years he was engaged in theoretical and experimental investigations on gravitation, light, heat and electricity. He was a frequent contributor to astronomical journals and periodicals.

SCHAEFFER, Nathan C., American clergyman and educator: b. Maxatawny, Berks County, Pa., 3 Feb. 1849; d Lancaster, Pa., 14 March 1919. In 1867 he was graduated at Franklin and Marshall College after which he studied divinity at the Theological Seminary of the Reformed Church and finished his education at the universities of Berlin, Tübingen and Leipzig. From 1875 to 1877 Dr. Schaeffer was professor at Franklin and Marshall College and from 1877 to 1893 was principal of the Keystone State Normal School. In the year last named he became State superintendent of public instruction, a post he held until his death. He also served as president of the State board of education and was president of a commission that prepared a new school code for the State, and was a member of the simplified spelling board. In 1879 he received the degree of doctor of philosophy and in 1904 received the degrees of doctor of divinity and doctor of laws from Dickinson College. He was a prolific writer on educational and religious subjects. His works include 'Thinking and Learning to Think' (1900); 'History of Education in Pennsylvania'; (editor) 'Bible Readings for Schools' (1897); introduction to Hinsdale's 'Civil Government'; Riddle's 'Nicholas Comenius'; 'Life of Henry Harbaugh,' and editor of the *Pennsylvania School Journal* after 1893.

SCHAFF, shäf, **David Schley,** American Presbyterian clergyman and educator, son of Philip Schaff (q.v.): b. Mercersburg, Pa., 17 Oct. 1852. He was graduated at Yale in 1873 and in 1877 was ordained in the Presbyterian ministry. He served as pastor in 1877–1907; was professor of church history at Lane Theological Seminary in 1897–1903; at Western Theological Seminary, 1903–25; and lecturer on church history, Union Theological Seminary, from 1925; delegate, Presbyterian Council, Aberdeen, Scotland, 1913. He was one of the editors of the 'Schaff-Herzog Encyclopedia' (4 vols., 1883); and of 'History of the Christian Church' (Vols. I–II, 1907–10); author of 'Life of Philip Schaff' (1897); 'John Huss' (1915), etc. He translated 'The Church' by Huss (1915). D. Winter Park, Fla., 2 March 1941.

SCHAFF, Philip, American clergyman and scholar: b. Coire, Switzerland, 1 Jan. 1819; d. New York, 20 Oct. 1893. He studied at Tübingen, Halle and Berlin, and was a lecturer in the latter university in 1842–44. He then came to this country where he was professor in the theological seminary of the German Reformed Church at Mercersburg (Pa.) 1844–63. In 1864–69 he was lecturer in several theological institutions, and in 1870 became professor of sacred literature in Union Theological Seminary, New York. This post he held until his transference in 1887 to the chair of church history in the same institution. He was one of the founders of the Evangelical Alliance and went as delegate to its general conferences at Basel in 1879, and at Copenhagen in 1884. He was president of the American Bible-revision committee, organized by him in 1871 at the request of the British committee. He was a prolific writer and editor, his works including 'History of the Apostolic Church' (1853); 'History of the Christian Church' (1867; new and enlarged edition, 7 vols., 1889–92); 'Creeds of Christendom' (1877); 'Schaff-Herzog Encyclopedia of Religious Knowledge' (as editor); 'Dictionary of the Bible' (1880); 'Church and State in the United States' (1888); 'Literature and Poetry' (1890).

SCHAFFHAUSEN, shäf'how-zĕn, Switzerland: (1) Capital of the canton of its own name, situated on an eminence overlooking the Rhine, 24 miles north of Zürich. It is quaintly and irregularly built. The buildings most worthy of notice are the feudal castle of Munot, of Roman construction, standing on a commanding height; the parish or Saint John's Church; and the cathedral (1052), a massive basilica containing a bell whose inscription suggested Schiller's 'Song of the Bell,' and Longfellow's 'Golden Legend'; the town-house (1412); the Imthurneum, containing theatre, concert rooms, etc., the museum containing manuscript collections of Johann von Müller, who was born here, the town library, etc. There are primary and high schools. The environs are beautiful; three miles distant are the celebrated falls of the Rhine, almost 300 feet broad, falling more than 70 feet in three cascades formed by two pillars of rock. The Fäsenstaub is a fashionable promenade. The principal industrial works are the wagon and carriage factories, cotton and woolen manufactories, iron works, distilleries and breweries. Pop. about 21,000. (2) The canton of Schaffhausen covers an area of 114 square miles, and occupies the most northern angle of the Swiss territory. It belongs to the Swabian Jura, and the population uses almost exclusively the German tongue. The canton entered the Swiss Confederation in 1501, and by the constitution of 1876 became exceedingly democratic. Education is compulsory. The taxes are very low. Financially it is the most favored among the Swiss cantons. All the cereals are raised, besides hemp and flax. There is abundance of fruit, especially grapes. The principal manufactures are aluminum, wagons, wool, ropes and watches. Pop. about 51,000.

SCHAFFLE, shā'flĕ, **Albert Eberhard Friedrich,** German political economist and sociologist: b. Nurtingen, Würtemberg, 24 Feb. 1831; d. Stuttgart, 24 Dec. 1903. He was educated for the ministry at Tübingen but adopted a journalistic career. In 1861 he was called to the University of Tübingen as professor of political economy, and in 1868 to Vienna. His principal contributions to the literature of political science are his 'National Economy' (1861-73); 'Capital and Socialism' (1870); 'The Fundamental Principles of Taxation' (1880);

and 'Quintessence of Socialism' (1884, 8th ed., 1885). In 1895 he began to write upon sociological questions and to develop the biological theory of society. His 'Bau und Leben des socialen Kőrpers' is a more detailed attempt to explain society as a living organism than that essayed by any previous writer. This book, completed in 1896, placed him in the ranks of modern sociologists.

SCHAFFNER, Jakob, German novelist: b. Basle, Switzerland, 15 Nov. 1875. He carried on his university studies in his native city, and there he wrote most of his works until he changed the scene of his studies to Charlottenburg, near Berlin, in 1912. His best novels are 'Irrfahrten' (Berlin 1905; title later changed to 'Irrfahrten des Jonathan Bregger' 1912), and 'Die Erlhőferin' (Berlin 1908, 15,000 sold in two years). His early poverty is reflected in most of his works, 'Irrfahrten' ("Wanderings"), for instance, has convincing pictures from the life of working people in their daily toil, while 'Konrad Pilater' is a story of a rather whimsical journeyman shoemaker (embodying scenes of Schaffner's boyhood as a shoemaker). Later books are 'Konrad Pilater' (Berlin 1910); 'Der Bote Gottes' (1911); 'Die goldene Fratze' (Berlin 1912); 'Erlösung vom Klassenkampff' (1920); 'Der Kreiselspieler' (1926). 'The **Iron Idol**' nas appeared in English.

SCHALCKEN, shäl'kĕn, **Godfried,** Dutch artist: b. Dordrecht, 1643; d. The Hague, 16 Nov. 1706. He was the pupil of Samuel van Hoogstraten and Gerard Douw. He visited England where he painted portraits, especially one of William III. His best work is in genre, and here he approached though still remaining inferior to his master Douw. He was fond of representing scenes by candle light, though he was scarcely ever quite true in the color representation of such light. When he attempted portraits in full length, as the fashion of the time of Sir Godfrey Kneller demanded, his efforts were not successful, with the possible exception of the portrait of William III, now in the Amsterdam Museum, but he soon became sensible of his error, and again painted on a small scale. Some of his best works are at the museums of Vienna, Dresden, Munich, Berlin, Amsterdam, The Hague, and at the Louvre.

SCHAMYL, shä'mĭl (Samuel), Tartar imam and warrior, leader among the tribes of the Caucasus: b. Aul Himri, northern Daghestan, 1797; d. Medina, March 1871. From 1824 to 1831 he took energetic part in Kasi Mollah's "holy war" against the infidel Russians, being severely wounded at the storming of Himri. A Sufi, he labored for the recrudescence of his faith in Daghestan, and was markedly successful. From 1837 he was temporal and spiritual head of the mountain tribes. His guerrilla method of warfare long enabled the Circassians to continue the struggle against Russia. During the Crimean War he was supplied by the allies with arms and money. After incredible escapes he was at last taken (6 Sept. 1859), and kept under surveillance, though treated with consideration.

SCHARF, shärf, Sir **George,** English artist: b. London, 16 Dec. 1820; d. Westminster, 19 April 1895. He studied art under his father, a Bavarian artist who had settled in England, and in 1838, after gaining medals from the Society of Arts, entered the Royal Academy schools. In 1840 he visited Asia Minor, and again in 1843 as draughtsman to a government expedition. On his return he devoted himself to painting in oil and to book-illustration, among the books illustrated by him being Murray's 'Prayer Book,' Macaulay's 'Lays,' Milman's 'Horace,' Kugler's 'Handbook of Italian Painting,' Layard's books on Nineveh, Keats' Poems, and Sir W. Smith's Classical Dictionaries. He rendered valuable assistance to the Crystal Palace authorities in planning the Greek, Roman and Pompeian courts, and to Charles Kean in his Shakespeare revivals of 1851–57. He was art secretary to the Manchester exhibition of 1857, and on the foundation of the National Portrait Gallery he began to make a special study of portraits, on which he soon became a recognized authority, and in 1882 he received the title of director of the gallery. His publications comprise 'Recollections of Scenic Effects' (1839), the part on sculpture in Waring's 'Art Treasures of the United Kingdom' (1857). To his great knowledge and industry the National Portrait Gallery owes almost its whole value.

SCHARF, John Thomas, American historian: b. Baltimore, Md., 1 May 1843; d. there, 28 Feb. 1898. At the outbreak of the Civil War he entered the Confederate army, was engaged in the battles around Richmond, at Cedar Mountain, the second Battle of Bull Run and at Chancellorsville, and in 1863 became a midshipman in the Confederate navy. He participated in the capture of the *Underwriter,* near New Berne, N. C., and after the blockade was established he again joined the army. While on his way to Canada with dispatches he was captured. In 1874 he was admitted to the bar, was a member of the legislature in 1878 and in 1884 he was appointed commissioner of the land office of Maryland. He was editor of the Baltimore *Telegram* and of the *Morning Herald* and wrote 'Chronicles of Baltimore' (1874); 'History of Maryland' (3 vols., 1879); 'History of the Confederate States Navy' (1887); 'Natural and Industrial Resources and Advantages of Maryland' (1885–90), etc.

SCHARNHORST, shärn'hŏrst, **Gerhard Johann David von,** Prussian general: b. Bordenau, Germany, 12 Nov. 1755; d. Prague, 28 June 1813. He entered the Hanoverian army in 1780 and soon distinguished himself as an officer of artillery. In 1804 he was knighted by the king of Prussia, and in 1813 attained the rank of general in the Prussian army. In the reorganization of the army of Prussia in 1809–13 he proved himself an able general. The national spirit, awakened by the loss of the territories west of the Elbe, was greatly augmented by the genius of Scharnhorst, who infused the military spirit throughout the scattered populations of the Prussian domain by raising a large and well-disciplined volunteer army for the War of Liberation. In this campaign he was chief of staff under Blücher, but was mortally wounded at the battle of Lützen. Consult 'Life by Lehmann (1886–87); von Boyen, 'Erinnerungen' (1891).

SCHAUMBURG-LIPPE, shoum'bo͝ork-lĭp'ĕ former *Land* (state) in northwest Germany, merged in 1945 into the new *Land* of Lower Saxony in the British zone of occupation. At the time of its dissolution it had an area of 131 square miles; the population in 1939 was 54,162; the capital was Bückeburg. The region includes agricultural and mining districts. Philip, youngest son of Count Simon VI of Lippe (1555–1613), inherited little of the paternal estate but in 1640 fell heir to a large part of the countship of Schaumburg, including Bückeburg. He thus became the first count of Schaumburg-Lippe. In 1807 the county was erected into a principality and its rulers became sovereign princes. With Germany's collapse in 1918 the reigning prince abdicated and the principality declared itself a republic, adopting a constitution in 1922. It continued to exist as a *Land* of the German Republic until 1945.

SCHECHTER, shĕk'tĕr, **Solomon,** Hebrew scholar and theologian: b. Focşani, Rumania, 1847; d. New York, N. Y., Nov. 19, 1915. A student of Hebrew from his earliest years, he lectured on the Talmud at Jews' College, London, was appointed reader in Talmud and rabbinical literature at University College, Cambridge, England (1890), and professor of Hebrew at the University of London (1899). While traveling in Egypt he discovered a store of Hebrew and Arabic manuscripts, known as the Genizah fragments. Among them were lost portions of Ecclesiasticus, which Schechter published as *The Wisdom of Ben Sira* (1899). A leader of the Conservative wing of Judaism, he opposed the Reform movement, and as a Zionist believed that Zionism should be a movement religious in nature and not merely nationalistic. In 1901 he was invited to the United States to become president of the Jewish Theological Seminary in New York City. There he worked to strengthen Judaism, wrote many essays and books, was an editor of the *Jewish Encyclopedia,* and a supervisor of the translation of the Hebrew Bible into English (pub. 1917).

SCHEELE, shā'lĕ, **Karl Wilhelm,** Swedish chemist: b. Stralsund, then in Sweden, Dec. 19, 1742; d. Köping, May 21, 1786. Scheele worked as a pharmacist in Göteborg, Uppsala, and elsewhere, and in 1770 became a teacher of chemistry at Uppsala; but in 1775 he moved to Köping—to carry on his research in his own pharmacy for the rest of his life. His discovery of oxygen predated that of Joseph Priestley (q.v.), though his findings were published after Priestley's. He discovered many new substances, among them hydrogen sulphide, the salts of manganese, chlorine, baryta, glycerin, and numerous acids, including uric and lactic acid. The coloring matter he discovered in arsenic was named Scheele's green, and the mineral scheelite was named for him. See also Air; Oxygen.

SCHEELITE, shēl'īt, native calcium tungstate, $CaWO_4$. Molybdenum may partially replace tungsten (wolfram). It crystallizes in the tetragonal system, and frequently shows third order bipyramids. The specific gravity is 5.9–6.1, the hardness 4.5–5, and the luster is vitreous to adamantine. Pyramidal cleavage may be conspicuous. The color and streak are white when it is pure, but it may be brown, yellow, green, or red. It usually is fluorescent. Scheelite occurs in hydrothermal quartz veins, in contact metamorphic deposits, and in pegmatites. Associates are quartz, topaz, fluorite, cassiterite, molybdenite and wolframite. It is a minor source of tungsten. Found in Nevada, Arizona, California, Connecticut, British Columbia, Saxony, Bohemia, Brazil, and New South Wales, it was named for the Swedish chemist Karl Wilhelm Scheele (q.v.).

SCHEER, shār, **Reinhard,** German naval commander: b. Obernkirchen, Hesse-Nassau, Germany, Sept. 30, 1863; d. Marktredwitz, Bavaria, Nov. 26, 1928. A career in the German Royal Navy led to a command of the high seas fleet in 1909, promotion to admiral as department director of the navy in 1912, and, at the opening of World War I (1914), to command of the second battle squadron. He was famed for his submarine tactics. In 1916 he was made head of the high seas fleet and was in command at the Battle of Jutland (q.v), May 31, 1916. He was chief of the admiralty staff, and after the war retired to become a member of the Nationalist Party. He wrote two books on the German Navy in the war: *Germany's High Sea Fleet in the World War* (1920) and *From Sailing Ship to U-Boat* (1925). See also War, European—*11. Naval Operations.*

SCHEFF, shĕf, **Fritzi,** Austrian-American actress and singer: b. Vienna, Austria, Aug. 30, 1879; d. New York, N. Y., April 8, 1954. Appearing first in Munich (1898) as Marie in Gaetano Donizetti's *Daughter of the Regiment,* Fritzi Scheff made her American debut at the New York Metropolitan Opera House in 1900 as Marcelline in Ludwig von Beethoven's *Fidelio.* Later, abandoning a successful career in grand opera, she won a wider and more spectacular popularity in the operettas of Victor Herbert, which perfectly suited her charming, exotic personality.

SCHEFFEL, shĕf'ĕl, **Josef Victor von,** German poet and novelist: b. Karlsruhe, Germany, Feb. 16, 1826; d. there, April 9, 1886. Educated at Munich, Heidelberg, and Berlin, he entered state service at Säckingen (1850). His epic poem *Der Trompeter von Säckingen* (1853; Eng. tr. 1877) achieved immediate popularity and went into several hundred editions. His historical novel *Ekkehard* (1857; Eng. tr. 1867) was as well received.

SCHEFFER, shĕ-fâr', **Ary,** Dutch-born French painter: b. Dordrecht, Holland, Feb. 10, 1795; d. Argenteuil, near Paris, France, June 15, 1858. Scheffer was a pupil in Pierre Guerin's studio in Paris, where he met the young romantics with whom he is associated but was not in complete sympathy. Dante inspired such pictures as *Francesca da Ramini* (1822). Those inspired by Goethe were shown at the Paris Salon (1831) and though sentimental became very popular. Lord Byron and Johann von Schiller supplied other romantic subjects. Scheffer painted portraits, and historical and religious subjects. He also produced lithographs and etchings. Admired in France in his day, and represented in the Luxembourg, in the Wallace Collection, London, and at Versailles, he is not now considered to be of the first rank.

SCHEIDEMANN, shī'dĕ-män, **Philipp,** German Socialist leader: b. Cassel, 26 July 1865; d. Copenhagen, Denmark, 29 Nov. 1939. He joined the Socialist party at an early age, and became editor of the party paper in Giessen. Soon afterward he was elected a Socialist member of the Reichstag. In 1913 he toured the United States, lecturing before many German-speaking branches of the Socialist party. In August 1914 he began rallying the Socialist-Democrats to the support of the Imperial government, having already defended Germany's declaration of war on France and Russia. As leader of the Majority Socialists, he supported the German war policies until July 1917, when he joined forces with Erzberger, a Centre Party leader, who foresaw the early collapse of Austria, and who advocated the finish of the war in a peace without annexations or indemnities. The internal revolution of November 1918 followed; and on 9 November, the date of the abdication of Kaiser Wilhelm II, Scheidemann resigned his position as Secretary of State without portfolio, and from the Parliament Building proclaimed the new German Republic. With Friedrich Ebert as Chancellor, and the Majority Socialists in power, the provisional government was soon able to subdue all counter-revolutionary movements. Scheidemann was elected president of the first Republic Ministry in February 1919, but resigned in June of the same year after refusing to sign the Versailles Treaty. He served as leader of the Majority Socialists in the Assembly and Reichstag, however, until the advent of the Hitler régime, when he fled to Czechoslovakia. From there he went to Poland, and then to Denmark in 1934, where he remained until his death.

SCHEINER, shī'nēr, **Christolph,** German astronomer: b. at Waldt in Swabia, about 1575; d. 1650. Scheiner was professor of Hebrew and mathematics at Freiburg and at Ingolstadt from 1610–16, and after several years' residence in Rome he became rector of the Jesuit College at Neisse in Silesia. In 1612 he published his 'Tres Epistolæ ad Marcum Velserum' and claimed to have seen sun spots as early as March 1611. He thus antagonized Galileo whom he further provoked by upholding the old thesis of a «stable» earth and a «mobile» sun. 'Rosa Ursina' (1630) was his great work on the sun and contained the results of about 2,000 observations.

SCHELDT, skĕlt, or **SCHELDE,** shĕl'dĕ (ancient SCALDIS), a river belonging in the various parts of its course to France, Belgium and the Netherlands. It rises in the French department of Aisne, at a height of 295 feet above sea-level, in the small lake of Beaurevoir, near Catelet. It flows northerly to Cambrai, Valenciennes, Boudain and Condé, where it first becomes navigable after junction with the Saint Quentin Canal. It enters Belgium between Montagne and Hollain, passes Doornik, Oudenarde, Ghent, Dendermonde, Rupelmonde, Tournai and Antwerp; at Ghent is joined by the Lys and the canals which connect that city with Sas and Bruges. There is considerable tide at Ghent, somewhat modified by sluices. The river makes a great bend toward Dendermonde and Antwerp, flows circuitously north forming the boundary between Antwerp and East Flanders provinces. At Antwerp it measures 1,600 feet in width, 45 feet in depth and still wider below, forms a secure harbor, which is capable of receiving the largest ships. Again turning northward, it is finally lost in the estuaries among the islands of Zealand. After reaching the Dutch frontier it divides into the East and West Scheldt, the latter and main stream flowing into the North Sea, below Flushing. Both branches connect with the Meuse and the Rhine. The entire length of the river is 211 miles. Its principal affluents are the Haine Dender, the Rupel, the Sensée, Scarpe and Lys. In 1925 the Dutch and Belgian governments reached an agreement by the terms of which the Scheldt is to be open to warships in time of peace, but closed in time of war. This question has been a source of irritation since the treaty of 1839. A commission exercises control over the river and the Terneuzen Canal.

SCHELLING, shĕl'lĭng, **Felix Emanuel,** American educator: b. New Albany, Ind., Sept. 3, 1858; d. Mount Vernon, N.Y., Dec. 15, 1945. In 1881 he was graduated at the University of Pennsylvania, where he received the degree of LL.B. in 1883, that of A.M. in 1884, Litt.D. in 1903 and LL.D. in 1909. In 1893 he became John Welsh Centennial professor of English literature at the University of Pennsylvania. Dr. Schelling was a member of the National Institute of Arts and Letters, of the American Philosophical Society, and of the Modern Language Association of America. He published *Literary and Verse Criticism of the Reign of Elizabeth* (1891); *Life and Works of George Gascoigne* (1893); *A Book of Elizabethan Lyrics* (1896); *A Book of 17th Century Lyrics* (1899); *The English Chronicle Play* (1902); *The Queen's Progress and Other Elizabethan Sketches* (1904); *History of Elizabethan Drama* (1908); *English Literature During the Lifetime of Shakespeare* (1910); "The Restoration Drama" in *Cambridge History of Literature* (1912); *The English Lyric* (1913); *A History of English Drama* (1914). He edited *Ben Jonson's Discoveries* (1892); *Eastward Ho and the Alchemist* (1903); *Macbeth* (1910); and *Beaumont and Fletcher* (1912).

SCHELLING, Friedrich Wilhelm Joseph von, German philosopher: b. Leonberg, in Württemberg, 27 Jan. 1775; d. Ragaz, Switzerland, 20 Aug. 1854. He studied theology and philosophy at Tübingen and natural science at Leipzig. His philosophy of nature as presented in 'Ideen zu einer Philosophie der Natur' (1797) and in 'Von der Weltseele' (1798), gained for him an appointment as professor at the University of Jena (1798). There he became the leading philosopher of the «early romanticists» and was highly esteemed by Goethe. In 1803 he married Caroline, the former wife of A. W. Schlegel (q.v.), and accepted a professorship in Würzburg. From 1806 to 1820 he lived in Munich as a member of the Academy of Science and also (since 1809) as general secretary of the Academy of Arts. He resumed his academic work from 1820 to 1827 at Erlangen, and from 1827 to 1841 at Munich. The theosophical turn of his later works induced Frederick William IV of Prussia to call him to the University of Berlin (in 1841), as a counterweight against the radi-

cal left wing of Hegel's disciples. But his lectures on mythology and revelation met with scant success and he retired in 1846. Among the ever-changing phases of his philosophical evolution two main periods may be distinguished; the first, which found its consummation in his "system of identity," is pantheistic in its general character; in the second period, beginning about 1806, he elaborates his "positive" philosophy, which rests on a theistic and theosophical basis.

Schelling had originally started as a disciple of Fichte's "Philosophy of the Ego," but his study of Spinoza and his own love of nature soon induced him to attempt a vindication of the external world, which Fichte had degraded by defining it as the mere "Not-self." In Schelling's Philosophy of Nature the external world is the preliminary stage (Vorstufe) of the Spirit. Nature is the unconscious side of the "Absolute" or "Infinite," just as the Spirit is its conscious side. Like Fichte, he conceives the "Absolute" as a process, as an activity (not as a substance) which continuously ascends from lower to higher forms of development. In carrying out this scheme he made use of many of the new ideas and discoveries that were then revolutionizing the natural sciences. Polarity (as exhibited in the two poles of a magnet) appears to him as the principle of all phenomena of nature. Everywhere, he sees dualism and polarity: positive and negative factors which neutralize each other, leading up to and producing a new reality. By means of repeated steps from lower to higher potencies the "Soul of Nature" (Weltseele) unfolds itself. The primal dualism of expansion ("imponderable matter," ether) and contraction ("ponderable matter," gravity) reveals itself more distinctly in the magnetic, electrical and chemical phenomena of the inorganic world, and in the corresponding functions of reproduction, irritability and sensibility of living organisms.

In the phenomena of sensibility the external order of things reaches its culminating point. But the same processes of polarity and evolution appear again on a different plane in the inner world of conscious existence. In his 'System of Transcendental Idealism' (1800; extracts translated in Prof. Benj. Rand's 'Modern Classical Philosophers,' 1908) Schelling represented the "Epochs of Self-consciousness" as parallel to the successive stages in the development of nature. Finally, the objective and subjective side of ourself (or the theoretical and the practical attitude of the mind, or intellect and activity) are carried to their harmonious union in the world of art and poetry. In art the human mind achieves the actual synthesis of the conscious and the unconscious. Art is the organ of the true philosopher; his highest aim must be a new mythology, which is to unite philosophy and poetry in objective representation.

The first period of his philosophy found its final expression in his "system of identity," as set forth in the 'Darstellung meines Systems' (1801), in the platonic dialogue 'Bruno' (1802) and in the 'Methode des akademischen Studiums' (1803). Merely comprehended by the analytical and formal faculty of the intellect, the universe divides itself into the two great regions variously denominated as Nature and Self, Matter and Spirit, Real and Ideal. But the connecting faculty of reason or "intellektuale Anschauung" (intellectual sight or perception, which is akin to the "intuition" of artistic genius) shows the antithesis of the two regions as only relative. Both are originally and essentially One; they are only two different forms of manifestation of the One Infinite. The Infinite or Absolute is the eternal Identity of the Real and the Ideal, which are the two poles of the Absolute. The process of the Universe consists in the splitting up of the original "absolute Indifference" into the opposites that were latent in it, and in the striving for a reunion of the "differences" in an ultimate absolute Identity. This active process of the Absolute, ascending from "indifference" through polar differentiation toward "identity," is also conceived by Schelling, in this period, as identical with the evolution of God.

After 1806, Schelling gradually became convinced that this rationalistic pantheism, which he now stigmatized as "negative," must find its counterpart and consummation in a "positive" system. The "thread of dialectical movement may be sufficient as a guide through the world of the purely rational but it breaks as soon as it takes the weighty step into reality," into the world of empirical specification. Here the contingent must be added to the necessary, and rational knowledge must be supplemented by irrational, but definite, experience of a higher order, which acquires the character of "Revelation." The creation of the World is now the free act of a supernatural and personal God; the actual or contingent world has come into existence by a mystical falling away from the original identity in which it lived in the bosom of the Absolute and Divine Being. Schelling's 'Essence of Human Freedom' (1809) shows clearly the influence of Jacob Böhme's theosophy. His 'Philosophy of Mythology and of Revelation,' published after his death, consists of mystical speculations about pagan mythology and Christian doctrines. He distinguishes a Petrine and a Pauline Christianity which are represented in the Catholic and Protestant churches. Both are dominated by the Johannine theology which is the highest form of Christianity.

As an eclectic of the highest order, Schelling assimilated and welded into an imposing synthesis such divergent types of human thinking as Kant, Spinoza, Leibniz, Fichte, Plato, Bruno, Böhme, Plotinus and the Gnostics. His philosophy of nature alone gained an immediate and powerful influence, not only in Germany, where Goethe, the romanticists and most of the scientists considered him as their philosophical spokesman, but in the rest of Europe also through disciples like Coleridge and V. Cousin. His conception of one continuous process of evolution which would embrace in successive steps the lifeless and the living world, was a great philosophical anticipation and did much to promote a scientific study of nature. But his method of reasoning by suggestive analogies and, in general, the artistic turn of his mind brought him into discredit among the younger school of exact scientists. For a time it was customary to deride him as the founder of "speculative physics." But many of his leading

ideas have since been vindicated before the scientific world.

TRAUGOTT BOHME.

Bibliography.—Schelling's complete works were collected and published by his sons in 14 vols. (Leipzig 1856–61); Beckers, Hubert, *Friedrich Wilhelm Joseph von Schelling* (Munich 1855); Noack, L., *Schelling und die Philosophie der Romantik*, 2 vols. (Berlin 1859); Beckers, Hubert, *Ueber die Bedeutung der Schellingschen Metaphysik* (Munich 1866); Hartmann, Eduard von *Schelling's positive Philosophie als Einheit von Hagel und Schopenhauer* (Berlin 1869); Watson, John, *Schelling's Transcendental Idealism* (Chicago 1892); Hartmann, Eduard von, *Schelling's philosophisches System* (Leipzig 1897); Adam, M. F. J. L., *Schelling's Kunst philosophie die Bergründung des Idealistischen Prinzips in der moderen Asthetik* (Leipzig 1907); Braun, Otto, E. L., *Die Entwickelung des Gottesbegriffes bei Schelling* (Leipzig 1908); Dewing, Arthur S., *The Significance of Schelling's Theory of Knowledge* (Lancaster 1910); Fischer, Kuno, *Schelling* in *Geschichte der neueren philosophie*, vol. 6, 3d ed. (Heidelberg 1912); Jost, Johannes, *F. W. J. von Schelling* (Bonn 1927); Cohn, Jonas, *Potenz under Existenz. Eine Studie über Schelling's letzte Philosophie* (Basle 1934); Schneider, Robert, *Schelling's und Hegel's Schwäbische Geitesahnen* (Berlin 1936).

Bibliography revised in Encyclopedia Americana office.

SCHENCK, Robert Cumming, American diplomat: b. Franklin, Ohio, Oct. 7, 1809; d. Washington, D.C., March 23, 1890. He was graduated at Miami University in 1827, and remained there as tutor until 1830. In that year he became a student of law in the office of the Hon. Thomas Corwin at Lebanon, Ohio, and was admitted to the bar in 1831. He began the practice of law at Dayton, Ohio, and soon achieved marked success in his profession.

In 1840, during President Harrison's "Log Cabin" campaign, he was elected to the legislature of Ohio, and entered upon his political career. He soon became a leader in the Whig Party, and was recognized throughout his section as an able and effective public speaker. In 1843, after an exciting political contest, he was elected to his first term in Congress, retaining his seat until 1851, and becoming one of the most prominent leaders of his party at Washington. In 1851 he was appointed United States minister to Brazil, where he remained some years, and performed important diplomatic service.

When the Civil War began he promptly offered his services to the government, and received a commission of brigadier general of volunteers. He was severely wounded at the second battle of Bull Run, and his right hand and arm permanently disabled. He was later promoted to the rank of major general, and served in the army until December 1863, when he resigned his commission to accept a seat in Congress, to which he had been elected in the fall of 1862 over Clement L. Vallandigham (q.v.). General Schenck's military and political abilities were at once recognized and he was appointed chairman of the Military Committee of the House and rendered important and arduous services. He was three times elected to Congress. He served as chairman of the Committee on Ways and Means and became the leader of his party in the House. On Dec. 22, 1870 he was appointed minister to Great Britain by President Grant, a position which he filled with distinction until 1876. During this term of service he was appointed member of the historic Joint High Commission which assembled at Washington, and provided by treaty for the Geneva Conference, a measure that resulted in substituting arbitration instead of war in the settlement of the serious controversies that had arisen between Great Britain and the United States, regarding the Alabama claims and other important subjects. His tact and force, and his knowledge of international law, were most useful in determining the great questions involved.

SCHENCK, William Edward, American clergyman: b. Princeton, N. J., March 29, 1819; d. Oakenout, Pa., Dec. 14, 1903. He was graduated from Princeton in 1838, from the theological seminary there in 1841 and was ordained in 1843. He was engaged in pastoral work in New Jersey and New York until 1852, was secretary of the Presbyterian Board of Publication in 1854–1886 and its editor in 1862–1870, and from 1865 was a director of Princeton Theological Seminary. He published *Historical Account of the First Presbyterian Church of Princeton, N. J.* (1851); *Church Extension for Cities* (1854); *Nearing Home* (1863); *The Fountain for Sin* (1864); *Children in Heaven* (1867), etc.

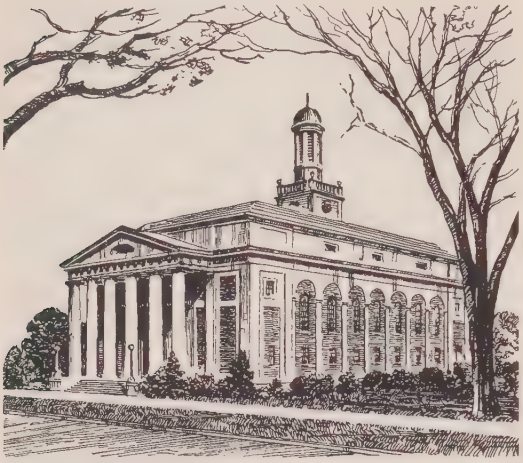
SCHENECTADY, city, New York, county seat of Schenectady County, altitude 211 to 275 feet; on the Mohawk River, new Barge Canal and on the New York Central Railroad and the Delaware and Hudson Railroad, about 15 miles northwest of Albany. It has connection with the Boston and Maine Railroad at Scotia and with the West Shore Railroad at South Schenectady. Local bus lines connect the city with Albany, Troy, Gloversville, Saratoga Springs, and other nearby places. Schenectady County airport is located ten minutes from the center of the city.

Buildings and Municipal Improvements.—The principal buildings are the post office, city hall, county courthouse, new state armory, the Young Men's Christian Association, the Young Women's Christian Association, the Schenectady County Tuberculosis Hospital, the City Hospital, Ellis Hospital, St. Clare's Hospital and Eastern New York Orthopedic Hospital. There are 96 churches, representing ten denominations. Union College has a beautiful Memorial Chapel.

Manufacturing.—Schenectady has a wide variety of industries, producing a labor supply that has become diversified. The General Electric Company has here its general offices and largest works which is the largest of its kind in the world and is also the largest industrial establishment in New York state. The American Locomotive Company also has its principal plant and main office in this city. Here also is located one of the oldest and best known radio stations, WGY, the famous short wave station, WGEO, the television station WRGB; frequency modulated stations WGFM and WBCA and local station WSNY. In addition to industries already mentioned there are manufacturers of mica insulators, printing and bookbinding establishments, ice cream and dairy products plants, baseballs, gloves, varnishes and paints, bedding, building materials and supplies, plating works, lithographing, confectionery, cabinet works, etc. The Schenectady General Depot of the U.S. Army is located at South Schenectady and the U.S. Naval Supply Depot in Scotia.

Education.—Higher education is served by Union College, one of the oldest in the country, being founded in 1795. In addition, the public school system consists of three high schools, three junior highs; two combined junior and elementary

and 19 elementary schools. Also there are six parochial schools and two private schools. Of interest to historians and antiquarians are the Schenectady County Historical Society's building and the new Schenectady Museum. Many scientists of national repute are engaged in the General Electric laboratories here.



Memorial Chapel, Union College, Schenectady, New York.

Government.—In 1906 Schenectady discarded its third-class city charter and became a second-class city. On Jan. 1, 1936, the city-manager-council form of government went into effect. The council of seven members, including the mayor, is nominated and elected at large. The term of office is four years, with three councilmen elected every two years and the mayor every four years. The city manager, the administrative head who serves at the council's pleasure, is appointed by the city council.

History.—Schenectady was settled in 1661 by Arent Van Curler, and letters patent were granted in 1684. On Feb. 8, 1690, the place was attacked by a force of French and Indians, who massacred all but 60 of the inhabitants and burned the town. In 1765 it was incorporated as a borough and in 1798 chartered as a city. Among the early steam railroads in the United States was one from Albany to Schenectady. The water communication by means of the Mohawk, increased by the new Barge Canal and the railroad communication at an early date, all contributed toward making the city a commercial and industrial center. It has increased steadily in population and industries. Pop. (1880) 13,655; (1890) 19,902; (1900) 31,682; (1910) 72,826; (1920) 88,723; (1930) 95,692; (1940) 87,549; (1950) 92,061.

SCHENK, Leopold, Austrian embryologist: b. Urmeny, Hungary, Aug. 23, 1840; d. Schwanberg, Styria, Austria, Aug. 17, 1902. He was graduated at Vienna University in 1865 and was appointed assistant professor of embryology there in 1873. He attained worldwide notoriety, and the censure of the medical profession generally, for his theories concerning sex control of the embryo through the diet of the mother. He also worked the theory into an elaborate plan for control of the development of the race. He was eventually forced to resign his position in the university. He wrote several textbooks and *Einfluss auf das Geschlechtsverhältniss des Menchen und der Thiere,* Eng. tr., *The Determination of Sex* (1898).

SCHERER, shā-râr', **Edmond,** French journalist: b. Paris, France, April 8, 1815; d. Versailles, France, March, 16, 1889. He studied at the law faculty of Paris, took a course in theology at Strasbourg, entered the Protestant ministry in 1840 and in 1845 became professor of exegesis in the École Evangelique, Geneva, popularly known as L'Oratoire. This he resigned in 1849 and became leader in the liberal movement in Protestant theology. He was elected to the National Assembly from Seine-et-Oise in 1871, and became a life senator in 1875. In both chambers he was a prominent representative of the left center.

He was made chief literary critic of *Le Temps* in 1860, later its editor. He took rank as a brilliant though opinionated critic, his reputation in this field having been made by a series of articles on important thinkers and writers of other literatures in the *Revue des Deux Mondes.*

SCHERESCHEWSKY, skĕr-ĕs-kūs'ki **Samuel Isaac Joseph,** American Protestant Episcopal bishop: b. Tanroggen, Lithuania, Russia, May 6, 1831; d. Tokyo, Japan, June 9, 1906. He studied in Russia and Germany, and, after coming in 1854 to the United States, at the Western Theological Seminary (Allegheny, Pa.) and the General Theological Seminary; was ordained deacon of the Protestant Episcopal Church in 1859, priest in 1860 and was a missionary in China in 1860–1875. In 1877 he was consecrated third Protestant Episcopal bishop of China, but he resigned his office in 1883 and afterward resided in the United States, China, and Japan. With J. S. Burden he translated the Book of Common Prayer into Mandarin, and he also prepared a complete revision of the Mandarin Bible (1895) and a wholly new rendering of the Bible into Wenli, the classical language of China (1902).

SCHERMAN, shûr'măn, **Harry,** Canadian-American writer: b. Montreal, Canada, Feb. 1, 1887. He was educated in the Philadelphia public schools and at the Wharton School of Finance, and Law School, University of Pennsylvania. He was one of the organizers of the Little Leather Library Corporation (1916) publishers of ten cent classics. He originated the Book-of-the-Month Club in 1926 and was its president until 1950 when he became chairman of the board.

He is the author of *The Promises Men Live By: a New Approach to Economics* (1931); *The Real Danger in our Gold* (1940); *The Last Best Hope on Earth* (1942).

SCHERR, shĕr, **Johannes,** German literary historian: b. Hohenrechberg, near Gmünd, Oct. 3, 1817; d. Zürich, Switzerland, Nov. 21, 1886. He was educated at the University of Tübingen, from which he received his doctorate in 1840, and subsequently settled in Stuttgart, where he became a teacher. As a leader of the Democratic Party, he took a prominent part in the revolution of 1848, and in the following year he was forced to flee to Zürich. Appointed professor of history and literature at the Polytechnikum there in 1860, he held this position until his death. Besides a four-volume satirical novel, *Michel: Geschichte eines Deutschen unserer Zeit* (1858), his published works include *Allgemeine Geschichte der Literatur* (1851); *Deutsche Kultur- und Sittengeschichte*

(1852–1853); *Geschichte der Religion* (1855–1857); *Schiller und seine Zeit* (1859); *Kulturgeschichte der deutschen Frau* (1860); and *Blücher, seine Zeit und sein Leben* (1862–1863).

SCHERZO, skĕr'tsō (Italian: a jest), a term applied to a movement in a symphonic composition having a playful, humorous, or capricious character. It may be said to have developed from the Joseph Haydn minuet and trio—in which form it is generally written—although the term was used before his time. Beethoven found in it a congenial channel of expression for his boisterous sense of humor, and in his hands it attained a recognized importance. Later composers have also written scherzos, though often their character is light and graceful rather than humorous. The term is occasionally given to an independent composition such as Chopin's scherzos for the piano.

SCHEVENINGEN, sĸā'vĕ-nĭng-ĕ(n), town, Netherlands, situated in South Holland Province, on the North Sea, 2 miles west of The Hague. A popular resort, the town also has herring fisheries and canneries. It suffered considerable damage during World War II, but reconstruction was rapid after the war. There are a number of parks, extensive woods, a boulevard along the ocean, and the Kurhaus, where concerts, recitals, and plays are given. Scheveningen is part of the commune of The Hague.

SCHIAPARELLI, skyä-pä-rĕl'lê, **Giovanni Virginio**, Italian astronomer: b. Savigliano, March 14, 1835; d. Milan, July 4, 1910. He was graduated from the University of Turin in 1854, and subsequently studied at Berlin under Johann Franz Encke, and at Pulkovo, Russia, under Friedrich Georg Wilhelm von Struve. Returning to Italy in 1860, he was appointed assistant observer at the Brera Observatory in Milan, and two years later became its director, a position he held until his retirement in 1900. In 1861 he discovered the asteroid Hesperia. He also observed numerous double stars, and he showed the relation between meteor swarms and cometary orbits. In 1877 he published the first accounts of his observations of what he called the canals of Mars. Schiaparelli was the author of many works on various phases of astronomy, including *Le stelle cadenti* (1873); *Norme per le osservazioni delle stelle cadenti dei bolidi* (1896); *L'astronomia nell' antico Testamento* (1903); and *Elementi di astronomia sferica* (1912).

SCHIAVONE, skyä-vō'nā, **Andrea** (real name Andrea Medolla or Meldolla), Italian painter: b. Dalmatia, 1522?; d. Venice, 1582. He was a pupil of Titian and became one of the finest colorists of the Venetian school. Among his works are *Christ Before Pilate* (Venice Academy); *Adoration of the Magi* (Ambrosiana, Milan); *Flight to Emmaus* (San Sebastiano, Venice); two landscapes (Berlin); *Holy Family* (Dresden); and *Christ Before Caiaphas* (Vienna).

SCHICK, shĭk, **Béla**, American pediatrician: b. Boglár, Hungary, July 16, 1877. He received his M.D. degree from Karl Franz University in Graz in 1900, and two years later began practicing medicine in Vienna. He was affiliated with the University of Vienna from 1902 to 1923, and from 1918 to 1923 was professor of pediatrics there. He went to the United States in 1923 and became an American citizen in 1929. Schick served as a consultant at the New York Infirmary for Women and Children and Mount Sinai, Sea View, Willard Parker, and Beth Israel hospitals in New York City, and from 1936 to 1943 was clinical professor of children's diseases at Columbia University. He is best known as the discoverer of the Schick test for determining susceptibility to diphtheria (1913). His published works include *Serum Krankheit* (with Clemens Pirquet, 1905); *Pirquetsche System der Ernährung* (1918); *Child Care Today* (with William Rosenson, 1933); and articles on diphtheria, scarlet fever, tuberculosis, and nutrition. In 1938 he was awarded a gold medal by the New York Academy of Medicine.

SCHIEDAM, sĸê-däm', town, Netherlands, situated in South Holland Province, near the confluence of the Schie and Nieuwe Maas rivers, 3.5 miles west of Rotterdam. Its principal industry is the distilling of gin. It also has shipyards and plants producing glass, bottles, chemicals, machinery, asbestos, cardboard, and crates. The town is intersected by numerous canals. Notable buildings include a 17th century town hall and the 15th century Great or St. Jans Church.

Schiedam was chartered in 1273 and developed as a fishing port until it was superseded by Rotterdam. Pop. (1951) 73,603.

SCHIFF, shĭf, **Jacob Henry**, American banker: b. Frankfurt am Main, Germany, Jan. 10, 1847; d. New York, N. Y., Sept. 25, 1920. He went to the United States in 1865 and joined a brokerage house in New York City. In 1870 he became an American citizen, and five years later was made a partner of the firm of Kuhn, Loeb & Company, of which he became the head in 1885. Schiff's leadership in the financial field was soon acknowledged. He participated in the financing of a number of railroads and insurance companies and in the marketing of foreign bonds, notably a Japanese issue in 1904 and a Chinese loan in 1911. He was also a generous benefactor of educational and charitable institutions, including Harvard University, where he endowed the Semitic Museum; the Jewish Theological Seminary, New York City; Tuskegee Institute; Cornell University, where he endowed a chair for the study of German culture; Barnard College; the American Red Cross; Montefiore Hospital, which he served as president; and the Boy Scouts of America.

SCHILLER, shĭl'ẽr, **Ferdinand Canning Scott**, English philosopher: b. Ottensen, near Altona (now part of Hamburg), Germany, Aug. 16, 1864; d. Los Angeles, Calif., Aug. 6, 1937. He was educated at Rugby and at Balliol College, Oxford. From 1893 to 1897 he was an instructor at Cornell University; from 1897 to 1903 assistant tutor at Corpus Christi College, Oxford; from 1903 to 1926 tutor there; and from 1929 to 1936 professor of philosophy at the University of Southern California. Schiller is best known as the leading English exponent of pragmatism, which he discussed under the term humanism. His published works include *Riddles of the Sphinx* (1891); *Humanism* (1903); *Studies in Humanism* (1907); *Plato or Protagoras?* (1908); *Formal Logic, a Scientific and Social Problem* (1912); *Problems of Belief* (1924); *Eugenics and Politics* (1926); *Cassandra, or the Future of the British Empire* (1926); *Social Decay and Eugenical Reform* (1932); and *Must Philosophers Disagree?* (1934).

SCHILLER, Johann Christoph Friedrich (von), German dramatist, poet, historian and philosophic thinker: b. Marbach in Swabia, 10 Nov. 1759; d. Weimar, 9 May 1805. His father was an officer in the army of the Duke of Württemberg, his mother a pious housewife nowise distinguished above her kind. The parents early decided to fit their son for the priesthood in the Lutheran Church. To this end they sent him to the Latin school at Ludwigsburg, which was then the ducal residence. Duke Karl Eugen was conspicuous among the German princelings who aped the style of the Bourbon kings, Ludwigsburg being his Versailles. Here he maintained a costly opera, spent large sums on building projects and governed through mistresses and adventurers. The boy Schiller had thus a good opportunity to observe the ways of petty autocracy under the old régime, and he used his eyes to good advantage. Presently the duke experienced a change of heart, became an exponent of virtue and went in for works of benevolence. In this spirit he founded a military academy which was to train the sons of his officers for the public service. That he might have the boys under his own eye and mold them to his liking, he assembled them under his own roof in his castle "Solitude," where for a time he played the schoolmaster with them. His offer of a scholarship to the boy Schiller was a princely favor not to be rejected by the loyal parents, though it involved giving up their plan of making him a pastor. To this school the lad went in 1773 and started in as a student of law, but floundered badly at first. After two years the school was transferred to Stuttgart, where it became virtually a university minus the theological faculty. A medical faculty was now added, and to secure students certain *élèves* (French was the official language of the school) were allowed to go over to medicine. Schiller, who had been at the foot of his class, eagerly accepted this chance. From this time (1775) on he devoted himself with average assiduity and success to medical studies. In 1780 he was honorably dismissed, but without a doctor's degree.

The discipline of the school was severely military. The students were kept under constant surveillance, their reading was censored and their quarters often searched for contraband books. But they found ways to smuggle in the forbidden literature, which of course tasted the sweeter for the prohibition. It is certain that young Schiller read nearly all the revolutionary productions — works of the so-called "storm and stress," — that were just then coming out. They soon raised his incipient radicalism to the boiling-point. A friend called his attention to a magazine story by Schubart dealing with a pair of enemy brothers, a theme just then in favor with the literary radicals. The hint was enough. Schiller, who by this time felt sure that the writing of tragedy was to be his vocation, began to pen his 'Robbers,' in which a dissolute but soft-hearted young nobleman named Karl von Moor, while leading a wild life as a Leipzig student, receives a harsh letter from his dotard father telling him that he is disinherited. Driven to fury by the missive and not suspecting the machinations of his scoundrel brother, Franz, he puts himself at the head of a band of scapegrace students and leads them to the Bohemian Forest, where they become outlaws and run amuck against society. Moor robs and murders on a terrific scale, yet not for vulgar gain. He tries to correct the inequalities and injustices of the social order, imagining that he is doing a righteous work as the avenger of the poor and oppressed, and fully believing that God is on his side. When he learns the truth he gives himself up to the law which he has outraged. Thus the play is a tragedy of fanaticism, and as such it marks the emergence of a new dramatic type. It has glaring faults of extravagance and overemphasis, but is none the less the work of a born dramatist, all clearly visualized for action and powerfully bodied forth. It was chiefly the fame of this thunderous play that led, in the course of time, to Schiller's being made an honorary citizen of the first French republic. There is an authentic tradition that in reading the scenes of the nascent 'Robbers' to his spellbound fellow-students, he would sometimes snort and roar and stamp in the white heat of his indignation.

Toward the end of 1780 he left the academy and was made army doctor to a regiment of invalid soldiers stationed at Stuttgart. The service was disagreeable and poorly paid. To increase his pittance of an income he borrowed money and published the play he had written, letting it appear anonymously as a book for the reader. It made no great stir as mere literature, but caught the attention of Dalberg, director of a theatre at Mannheim, who suggested a revision for the stage. Schiller complied and the new version was played at Mannheim in 1781 with memorable success. The audience went wild over the performance and the obscure army doctor at once emerged into the glare of notoriety, though he had saddled himself with a debt which was destined to afflict him for years. After such a success he was naturally disposed to try again. He wrote a second play, on the abortive conspiracy of Fiesco at Genoa in 1547, conceiving it at first rather vaguely as a "republican tragedy." Meanwhile he had got into serious trouble with his lord and master, the duke. In the first place, he had left his post without permission in order to attend the first performance of the 'Robbers' at Mannheim. Secondly, a passage in the published play had given offense in Switzerland and led to public complaints. The result was that Schiller was given two weeks in the guardhouse and forbidden to write any more "comedies." This was too much. He decided to quit Württemberg. One evening in September 1782 he stole away clandestinely with a friend named Streicher, a musician who afterward published an account of the episode. Under assumed names the pair went first to Mannheim, where Schiller read his new 'Fiesco' to Dalberg's actors and received the humiliating verdict that it was worthless and could not be played. He had ruined its effect by his bad reading, and besides that the politic Dalberg was in no haste to befriend a runaway who had quarreled with the ruler of a neighboring state. Schiller was now technically a deserter and had very good reason to fear that he would be pursued and put under arrest. So he took refuge at Bauerbach, near Meiningen, occupying a house that had

been put at his disposal by a friendly lady named Henriette von Wolzogen. At first he went under the name of Dr. Ritter and scattered misleading letters as to his whereabouts, but his friends soon learned where he was and it became evident that the Duke of Württemberg was taking no steps to have him arrested. Being now free for his favorite employment, he wrote a third play, which he at first called 'Luise Miller,' afterward 'Cabal and Love,' and sketched a fourth, which was to be known as 'Don Carlos.'

In the summer of 1783 he returned to Mannheim under a year's contract as theatre-poet, Dalberg having become convinced that there was no danger to be feared from Stuttgart and hoping that the new plays would repeat the huge success of the 'Robbers.' In due time 'Fiesco' was put on the stage with moderate success, but not as a "republican tragedy." By a stroke of the pen its author had given it a happy ending. Instead of being slain as a selfish usurper by the fanatical republican Verrina, Fiesco is made, in the moment of his triumph, to cast off his ducal robes and bid the Genoese embrace him as their happiest fellow-citizen. This ending clearly supports the republican idea, but we are hardly prepared for such a turn by the preceding trend of the play, which makes Fiesco continually vacillate between republican idealism and the lure of personal aggrandizement. 'Cabal and Love' is a tragedy of class-conflict and incidentally a drastic comment on the ways of German courts and courtiers. A high-minded nobleman falls in love with a fiddler's daughter and wishes to marry her in spite of her humble birth. But his father, who has risen by crime to the presidency of the ducal council, will have none of such a misalliance and concocts a vile plot to force his son into a marriage with the duke's mistress. This is the "cabal." The plotters succeed in making Ferdinand madly jealous, so that he poisons Luise and then commits suicide. In writing the play Schiller had the Württemberg court in mind, and little touches here and there reflect actual history. But the duke himself does not appear and there are no telltale names. 'Cabal and Love' has many strong scenes and is the only class-conflict play of that epoch which is still alive on the German stage. But its effect is marred at the last by the fatuous conduct of the tongue-tied heroine, who forfeits sympathy by her seeming lack of common sense.

The three plays just considered, all written in prose and characterized by a vehement, high-keyed diction, are the most important yet not the sole expression of Schiller's youthful radicalism. While still living in Stuttgart he started a magazine called the *Württemberg Repertory,* for which he wrote a number of minor papers. He also published a so-called *Anthology for the Year* 1782 containing numerous short poems. The dominant note of Schiller's early verse is a certain high-pitched vehemence which is apt to suggest poetic feigning. He is as far as possible from the simple realistic manner of the young Goethe, having a marked fondness for soaring and sonorous diction.

At the end of his first year in Mannheim the contract with Dalberg was not renewed, so that Schiller found himself in the summer of 1784 without income and without prospects. He was oppressed by debt and generally unhappy. Mannheim had become a prison. He decided to try his fortune by starting a dramatic magazine to be known as the *Rhenish Thalia,* but hardly had he launched it when he was called away from the Rhine country by a friendly message from Gottfried Körner, a young lawyer just then living in Leipzig. After a short sojourn in the university town Schiller followed his new-found friend to Dresden, where he remained nearly two years in intimate association with the Körner family. He continued to publish his magazine, now called simply *Thalia,* and at the same time worked in a desultory fashion on his 'Don Carlos.' This he had originally planned as a love-tragedy in a king's household, purposing incidentally to scourge the Spanish Inquisition. But the mood of the revolutionist and special pleader gradually gave way to the serener ambition of the poet and he decided to write his new play in verse, as Lessing had lately done in the case of 'Nathan.' In the illusory hope of receiving valuable criticism he began to publish it piecemeal in successive numbers of the *Thalia.* As he worked his mind changed, important characters began to appear in a new light and the centre of gravity shifted. The result was that the very long play completed in 1787 was something very different from the one he had conceived four years before. 'Don Carlos' is a tragedy of political idealism wrecked by a passion for intriguing methods and would-be heroic foolhardiness. The weightiest character is not the nominal hero, but the Marquis Posa, who pleads with Philip II of Spain to grant the Netherlanders freedom of thought and to end the Spanish régime of force and terrorism. Posa is a humane idealist of the 18th century and voices Schiller's own convictions as matured by his intercourse with Körner. Viewed in its relation to its author's personal development 'Don Carlos' occupies a middle position between the rather crude realism of his early prose plays and the matured art of his later and more famous poetic dramas. In 'Don Carlos' his peculiar sonorous diction begins to show itself at its best. But the play as a whole suffers from a lack of simplicity and clearness. It is too long and complicated for the three hours' traffic of the stage.

In the summer of 1787 having tired of his dependence on Körner, Schiller decided to try his fortune in Weimar, whose duke had previously given him the title of councillor. Goethe was then in Italy, but the visitor soon made the acquaintance of Herder and Wieland. Ere long he decided to settle in Jena and devote himself to the writing of history. He had now lost touch with the stage and his experience with it had been on the whole disappointing. On the other hand, he had become very much enamored of historical study, and his reading for 'Don Carlos' had given him a special interest in the great Dutch-Spanish conflict of the 16th century. He planned a bulky treatise of six volumes on the subject, but only wrote one. It was published in 1788 under the title 'Defection of the Netherlands.' The book is brilliantly written, the author's sympathies being obviously with the Dutch in their struggle for freedom, and contains a number

of splendid literary portraits. But Schiller got his information rather easily and made no very careful study of the sources. His merit as a historian has been often attacked and as often defended. At any rate he made literature out of history, the first achievement of that kind in the German language. His success as a historian led to his appointment, through Goethe's influence, to a professorship at the University of Jena. But hardly had he entered on his academic duties when a dangerous illness shattered his health. He never fully recovered, but led henceforth the circumspect life of a semi-invalid. A gift by the Duke of Augustenburg freed him temporarily from pecuniary anxieties — he was now married to the dowerless Charlotte von Lengefeld — and he resolved to devote his freedom to the study of Kant. He felt that critical thinking had largely destroyed his imaginative spontaneity and that the only possible cure lay in a further study of fundamentals: the «rules» must repair the damage they had wrought. So for several years he devoted himself about equally to history and philosophy, writing rather copiously in both fields. In the former we have his 'History of the Thirty Years' War,' which he conceived as a revolt of the Protestant princes of Germany against the centralizing despotism of the house of Hapsburg. It is eminently readable, especially where it treats of the great Swedish king who is Schiller's hero. He also wrote a number of minor historical papers. To enliven the columns of his *Thalia* he published in it his one attempt at prose fiction, the 'Ghostseer,' a fragmentary yarn which exploits various phases of contemporary interest in the supernatural. It is fair to call it a yarn because he himself never took it seriously and even called it a «Sudelei.» In general, this period of Schiller's life is rather barren of poetic production. To it belong, however, the 'Gods of Greece' and the 'Artists,' two of his weightiest and most famous poems. The former is an elegy on the lost beauty of Greek polytheism, the latter a glowing tribute to the influence of art in the upward evolution of human kind. In the philosophic domain Schiller devoted himself mainly to the theory of beauty and its relation, on the one hand to art, on the other to conduct. Setting out from Kant's analysis of beauty in the 'Critique of Practical Judgment,' Schiller reached the conclusion that beauty is fundamentally freedom-in-the-appearance. He set forth his doctrine and its implications in a number of rather forbiddingly abstruse essays, of which the most interesting one, perhaps, is that entitled 'Uber Anmut und Würde' ('On Winsomeness and Dignity'). In a more popular and readable form his philosophy of art is expounded in his 'Letters on Esthetic Education' and his famous essay on 'Naive and Sentimental Poetry.'

In 1794 began the famous friendship of Schiller and Goethe. For seven years the two men had lived as mutually indifferent neighbors, each acquainted with the other's work but neither caring for a closer relation. A casual meeting at a scientific lecture put an end to this mutual aloofness, explanations and visits ensued and ere long they were close friends and literary allies. Goethe became a frequent contributor to Schiller's magazine *Die Horen* and took a keen interest in its success. But it did not succeed and after three years was discontinued. It was largely their irritation over this failure that led the two men to unite in the literary campaign of the 'Xenia,' a collection of epigrams in the ancient distich form, wherein they paid their respects to men and tendencies they did not like. Nearly a thousand of the distichs were written and about half that number were published in 1797 in Schiller's *Musenalmanach,* where they caused great excitement. There was a shower of 'Anti-Xenia,' to which the perpetrators of the original «Teufelei» (as they called it) paid no attention. They agreed that the published 'Xenia' should be included in the works of both, and that they would give no information as to their separate authorship. Some of the epigrams are sharply censorious, others without any sting at all. The majority, relating as they do to men and matters of ephemeral interest, now seem rather pointless. Their chief historical importance is that they caused Schiller and Goethe to be generally regarded as militant allies fighting the same battle. The two men came to be known as the Dioscuri.

Schiller had now definitely returned to poetry. In conjunction with Goethe he made a study of the epic style and out of this study grew a number of ballads and romanzas which are among the most popular of his works. Special favorites of those who enjoy this phase of Schiller's art are the 'Diver,' the 'Pledge,' the 'Glove' and the 'Cranes of Ibycus.' To this period belong also a group of reflective poems in which he gave expression to the humane idealism and high ethical aspiration which characterize his mature thinking. In this domain he is at his best in the 'Ideal and Life,' the 'Walk' and the 'Song of the Bell.' But his fame rests mainly on his poetic dramas. As director of the little Weimar theatre Goethe was glad to avail himself of his friend's insight and experience in matters of the stage. Schiller, who became a resident of Weimar in 1799, gave assistance in selecting and adapting plays and gradually enriched the local repertory with five creations of his own which are the pride of the German classic drama. He began 'Wallenstein' in 1796, at first purposing to make it a play of ordinary length. The material proved refractory since it dealt only with what Schiller called the cold passions (ambition, hate, malice, vindictiveness), and also because it involved idealizing and creating dramatic sympathy for a traitor. Schiller met the first difficulty by inventing a pair of romantic lovers and managing the plot in such a way that the spectator is forced to see Wallenstein through their partial eyes; the second by giving to Wallenstein a certain loftiness of soul, making much of all the extenuating circumstances and surrounding him with inferior men among whom he towers like a giant among pigmies. The result is that a rather repellant character becomes grand in his final isolation and pitiful downfall. On the whole Wallenstein is the most impressive tragic hero created by any German dramatist. As Schiller's interest in the man and his times deepened the material grew on his hands until he decided to present it in three parts called 'Wallenstein's Camp,' the 'Piccolomini' and 'Wallenstein's Death.' It is, however, no

trilogy in the Greek sense, but a portentously long tragedy in 10 acts, preceded by a dramatic prologue.

Next came 'Mary Stuart,' indubitably the best for the stage of all the many plays in divers languages dealing with the famous Queen of Scots. Here the problem, as Schiller saw it, was to create genuine tragic sympathy for his heroine, but without extenuating her conduct and so making a distinctly Catholicizing play. He solved the problem by concentrating the plot into the last few days of Queen Mary's life and introducing her as a woman whose conscience is heavily burdened by the admitted crimes of long ago, but who feels that in her present plight she is the victim of rank injustice. As she is helpless to avert her impending fate, her situation, according to Schiller's conception of dramative art, is pathetic rather than tragic. It was necessary to make her in some sense visibly responsible for her calamity. To meet this dramaturgic difficulty Schiller resorted to two unhistoric inventions: first, Queen Mary's attempt to escape at the instigation of the Catholic renegade, Mortimer, this attempt endangering the life of Queen Elizabeth; secondly, a meeting of the two queens at which Mary loses control of herself and puts a deadly insult on her rival. This scene is the stage-climax of the play, but its psychological climax comes in the fifth act, when Queen Mary humbly accepts her ignominious death as a divinely appointed expiation for the sins of long ago. While the play's appeal is thus shifted from politics to religion and made to rest on a purely human basis that is neither Catholic nor Protestant, there is much in it that indicates Schiller's artistic sympathy with the Catholicizing tendency of the new romantic movement just then acquiring momentum. The portrait of Elizabeth is little better than a caricature.

Still more marked is the Catholicizing drift in the 'Maid of Orleans,' which was given the subtitle of "romantic tragedy" for the very reason that it requires us to accept the supernaturalism of the legend at its face value. Schiller follows the tradition rather closely except that he makes Joan's "voices" enjoin virginity as a condition of success in her patriotic mission, and that he departs radically from history in respect to the manner of her death. In his view of the matter tragic guilt of some kind was indispensable to tragedy; so he makes Joan fall strangely in love with the English general Lionel just as she is about to take his life on the battle-field. From that instant, feeling that she has violated the spirit of the divine command, she loses her self-confidence and with it her supernatural power. After great suffering and humiliation, which supposedly expiate her offense, she recovers her power by a miracle and dies in glory on the field of battle fighting for France. In this bold romanticization of the Maid's character it was Schiller's deliberate intention to idealize her and rescue her from the obloquy cast upon her by Voltaire's 'La Pucelle.'

His next play was the 'Bride of Messina,' in which he attempted to find a substitute for the Greek chorus. He invented a mediæval plot in which two brothers fall in love with the same girl, who is in reality their sister. She has been brought up in seclusion, her existence unknown to them, in order to defeat the dire prediction of soothsayers. Jealousy and mutual antipathy lead on to the death of both. Schiller provides each brother with a band of retainers who take part in the action and also function as semi-choruses, each speaking through a chosen leader. In what they say an attempt is made to imitate the detached attitude and lofty moralizing of the Sophoclean chorus. Schiller's noble poetic diction is at its very best in the 'Bride of Messina' and especially in the so-called choral passages; but it is evident that words spoken by one person, without group-singing or group-dancing, could convey hardly more than a dim suggestion of the old Greek chorus. Schiller's example has not been imitated and the 'Bride of Messina' is but rarely played.

Last came 'William Tell,' the most popular of all Schiller's plays. It is this stirring and intensely human drama dealing with the revolt of the Swiss farmers against the tyranny of their Austrian governors that has led to the idealization of its author as poet of freedom. It has no hero but the Swiss people, it lacks unity, it violates several of the most approved rules of dramaturgy. Yet there is an appealing charm about it which seldom fails to please, whether it is read as literature or seen upon the stage. After the completion of 'William Tell' in 1804 Schiller addressed himself to a new play on the story of the false Demetrius, reputed son of Ivan the Terrible. He made careful studies of Russian history, sketched numerous scenes and completed the better part of two acts. In the midst of this work on 'Demetrius' he contracted the illness which led to his premature death.

Schiller has always been regarded as the greatest of German dramatists. He had but little of the lyric gift and wrote no songs that have become highly popular. Fastidious critics have often taxed him with being a rhetorician rather than a poet, but anything like posing or insincerity was quite foreign to his nature. His personal character endeared him to all who knew him and he lived his life on a high plane of thought and feeling. His aspiring idealism has always appealed particularly to the young; so that his writings, popularized by school and theatre, are, or at least were, for the Germans a great educative force. His name, linked habitually with Goethe's, stands for all that is best in the best epoch of German letters. See under article headings WALLENSTEIN; WILHELM TELL.

Bibliography.— There is a vast quantity of literature pertaining to Schiller; consult Vol. V of Goedeke's 'Grundriss zur Geschichte der deutschen Dichtung' and the survey in the Appendix to Thomas's 'Life of Schiller.' Fairly recent contributions to literature are Frederic Ewen's 'Prestige of Schiller in England, 1788–1859' (1932), and Otto Peterson's 'Schiller in Russland, 1785–1805' (1934).

The first complete edition of Schiller's works was that of his friend Körner, 12 vols., 1812–15. This formed the basis of the later Cotta editions which appeared in different forms and different degrees of completeness. Down to about 1868 these were rather uncritically edited. Between 1868 and 1872 appeared the Historisch-kritische Ausgabe, 15 vols., edited by Goedeke and others. To the same period belongs the

cheap popular edition issued by Hempel, in Berlin — well edited but unsightly. Good later editions are those of Boxberger and Birlinger, forming part of Kürschner's Deutsche National-Literatur, 12 vols., and of Bellermann, 14 vols., 1895 ff. Of special merit is the Säkular-Ausgabe, 16 vols., 1904. The numerous letters of Schiller, where his style was at its best in Goethe's opinion, have been well edited by Jonas, 7 vols., 1892 ff. Editions of the separate plays, issued by competing publishers for school and college use, are numerous but cannot be listed here.

Biographies short and long are almost legion. Of the early ones those by Carlyle (1825) and by Karoline von Wolzogen, the poet's sister-in-law (1830), are still interesting, as is also the booklet 'Schiller's Flucht von Stuttgart' (1836) by his friend and fellow-traveler, Streicher. Between 1838 and 1842 Hoffmeister brought out his monumental treatise in five volumes, which was followed by the shorter work of Viehoff (1846) and Schaefer (1853). The centenary jubilee of 1859, at which Schiller was glorified as the poet of freedom by Germans all over the world, brought forth a mass of more or less eulogistic literature. Of the longer biographies dating from this epoch of Schiller enthusiasm the best is that of Palleske (1858–59), of which an English translation by Lady Wallace was published in 1860. Less fervid and also less readable are the biographies by Düntzer (1881) and Hepp (1885). Highly learned biographies, going deep into all sorts of minutiæ, were begun by Minor (2 vols., Berlin 1890) and by Weltrich (three instalments in one volume, 1899), but have remained unfinished. The same is true of the less exhaustive work of Brahm (Vol. I, 1892). An excellent illustrated life of Schiller is that of Wychgram (1891). Of solid merit also is the little book of Harnack (1898), the larger one by Kühnemann (5th ed., Munich 1914) and the two-volume treatise by Berger (8th ed., Munich 1914). In English, aside from translations, there are short biographies by Boyesen (New York 1882), Sime (Edinburgh 1882) and Nevinson (New York 1889); also a longer one by Thomas (New York 1901). The best translations of the poems are those of Bulwer Lytton (London 1844) and Arnold Foster (1902).

Noteworthy special studies (but the list is far from complete) are the following: Bellermann, 'Schiller's Dramen' (2 vols., 1898–99; 3d ed., 3 vols., Berlin 1905–08); Köster, 'Schiller als Dramaturg' (Leipzig 1891); Tomaschek, 'Schiller in seinem Verhältnisse zur Wissenschaft' (1862; which won a prize offered by the Vienna Academy); Harnack, 'Die klassische Aesthetik der Deutschen' (Berlin 1892); Rieger, 'Schillers Verhältnis zur französischen Revolution' (Berlin 1885); Wilm, 'The Philosophy of Schiller in its Historical Relations' (Boston 1913); Wiln, E. C., 'Philosophy of Schiller' (New York 1921).

Calvin Thomas,
Late Professor of Germanic Languages and Literatures, Columbia University.

SCHILLER, *in mineralogy,* a peculiar lustre due to reflection from the surfaces of minute enclosed crystals, probably of goethite. It is best illustrated by sunstone (q.v.), and is also noticed in bronzite, hypersthene and labradorite.

SCHILLING, shĭl'lĭng, **Johannes,** German sculptor: b. Mittweida, Saxony, 23 June 1828; d. 1910. He studied art at Berlin and Dresden. In 1868 he became professor at the Dresden Royal Academy. His chief works include the 'Four Seasons' at Dresden, statues of Schiller at Vienna, of Maximilian at Trieste, the War Memorial at Hamburg and the German National Monument on the Niederwald, opposite Bingen on the Rhine, which bears a colossal figure of Germania, and the statue of Wilhelm I at Wiesbaden (1894).

SCHINDLER, shĭnd'lẽr, **Solomon,** American rabbi: b. Niesse, Silesia, 24 April 1842; d. 5 May 1915. He came to America from Westphalia in 1871, having been for some years out of sympathy with orthodox Judaism, and, after a period of struggle in his adopted country, became known as one of the leaders of the advance movement among Hebrew religionists. He was called to the congregation of Adeth Israel in Boston, Mass., in 1884. In this pastorate he continued nearly 20 years, during which time he not only helped to liberalize the Hebrew faith but to promote a better understanding between American Hebrews and Christians than had before existed. In 1895–99 he was superintendent of the federated Jewish charitable organizations of Boston; in 1899–1909 superintendent of the Leopold Morse House; he then retired. He was author of 'Messianic Expectations and Modern Judaism'; 'Dissolving Views of the History of Judaism'; 'Young West, a Sequel to Bellamy's Looking Backward,' etc.

SCHINKEL, shĭn'kĕl, **Karl Friedrich,** German architect and painter: b. Neuruppin, Brandenburg, 13 March 1781; d. Berlin, 9 Oct. 1841. He was educated at the gymnasium of his native town, and after 1795 in that of Berlin. He became a pupil of Professor Gilly, and on the death of the latter in 1798 succeeded to his private practice as an architect. At the same time he continued his studies, and in 1803 he went with this object to Italy, returning in 1805 by way of France to Berlin. The period of the war being unfavorable for architecture, he took to landscape painting, and from 1808 to 1814 painted a series of dioramas for Gropius. On the return of the royal family to Berlin some of his designs for alterations in the palace were adopted and carried out. In 1811 he was admitted to the Academy, and in 1820 became a professor at the Academy. The designs to which chiefly he owed his architectural reputation include those of the royal guardhouse, the 'Memorial' of the War of Liberation, the new theatre, the new Potsdam Gate, the artillery and engineers' school, all in Berlin; and the observatory; the casinos in Potsdam and Glienicke; and a large number of castles, churches and minor public buildings. As a painter he produced numerous wall and easel pictures. His 'Primeval History of Mankind' in the vestibule of the Berlin Museum exhibits him to advantage as a wall painter. His landscapes are chiefly architectural views, of which the best known are the 'Theatre at Taormina'; 'Square of Saint Mark's, Venice'; 'Ocean Caves near Sorrento'; 'The Cathedral at Milan'; 'Interior of Saint Peter's, at Rome'; 'The Capitol by Moonlight.' He exercised a

profound influence over every department of the art production of his day, including carpet and furniture making.

SCHIPA, Tito, Italian operatic tenor: b. Lecce, Italy, 2 Jan. 1890. He studied under Alceste Gerunda, and came to the United States in 1919, joining the Chicago Opera Association the same year. His repertoire includes 'Sonnambula,' 'Barber of Seville,' 'Lakmé,' 'Traviata,' 'Lucia,' and 'Tosca.' He has been decorated Order of the Crown (Italy); Ordine Civil de Alfonso XII (Spain).

SCHIPKA PASS. See SHIPKA PASS.

SCHIPPERKE. See DOG.

SCHIRMER, shĭr'mĕr, **Johann Wilhelm,** German artist: b. Jülich, Rhenish Prussia, 5 Sept. 1807; d. Carlsruhe, 11 Sept. 1863. He studied historical painting under Schadow at the Düsseldorf Academy until he came under the influence of Lessing's landscapes, whereupon he turned to that *métier,* producing historical landscapes after the manner of Poussin. In 1830 he became assistant professor, and in 1839 professor at the Düsseldorf Academy, meantime visiting and painting in Belgium, the Black Forest, Switzerland, Holland, Normandy and Italy. In 1853 he became director of the art school at Carlsruhe. Among his works are six Biblical landscapes, with the 'Life of Abraham,' National Gallery, Berlin; 'Grotto of Egeria,' 'Nether German Landscape,' Leipzig Museum; series of 26 Biblical landscapes, Düsseldorf Gallery; 'Via Mala,' four landscapes with story of Good Samaritan; 'Storm on the Campagna,' Carlsruhe Gallery.

SCHIST (crystalline), a metamorphic rock generally found only in regions which have been subjected to regional or dynamic metamorphism, that is, those in which the strata have suffered intense folding and shearing. The general characteristics of schists are the fine and pronounced lamination, and crystalline character of component material. They grade on the one hand into gneisses and on the other into scarcely altered mica slates or sandstones. The more important varieties are broadly classified, according to the principal ferro-magnesian silicate present. Thus we have: (*a*) Mica schists; (*b*) Hornblende schists or Amphibolites, and (*c*) various minor schists. The mica schists range in silica from over 80 per cent to less than 50 per cent, according to the amount of quartz present. The most prominent and abundant minerals of this variety are quartz, muscovite and biotite, which are more or less distributed in layers. Among the other minerals present are feldspars, both orthoclase and plagioclase, the rock thus approaching gneiss; garnet, often in large and well-formed crystals; staurolite, cyanite, sillimanite, tourmaline, varying from black through blue, green, red, to white, often of the precious type; opalite, pyrite and magnetite. The term Hydromica schists is used commonly for the finer varieties, in which the scales of mica are indistinguishable (sericite, peragonite, etc.). These pass imperceptibly into phyllites. Mica schists result largely from the metamorphism of sandstones, shales and clays, but also through crushing and excessive shearing of igneous rocks. They are found over wide areas in New England, the Appalachians, Lake Superior and the West. The Hornblende schists or Amphibolites generally result from the dynamic metamorphism affecting igneous or pyroclastic rocks, and rarely from ordinary sedimentary rocks. Hornblende here takes the chief place, quartz being normally absent, while biotite and the basic feldspars are characteristic constituents. Garnet, magnetite, pyrite and other basic minerals are also common. These schists occur as belts in other metamorphic rocks, generally representing dikes, sheets, flows, or ash beds in the sedimentary series. They occur in New England and other Eastern States, and are important in the mineral regions of Lake Superior. They also occur in the Black Hills, and in the Rocky Mountain and California ranges. Among the minor schists may be mentioned chlorite schist, talc schist, epidote schist and others. In each of these, the mineral giving name to the rock is more or less admixed with quartz, feldspars and numerous other minerals. They probably result most commonly from the alteration of igneous rocks, and are found in the older metamorphic districts. See FOLIATION; METAMORPHISM.

SCHIZÆA, skī-zē'ą, the typical genus of the family *Schizæaceæ,* ferns widely distributed, mostly in tropical regions, and which are small and distinct in habit. The sporangia have an entire apical ring and are sessile in close distichous spikes along the middle veins of the narrow pinnæ of the fertile fronds; the sterile fronds are linear, fan-shaped or dichotomously many-cleft. *S. pusilla,* the curly-grass, is the only species in North America, and is very rare and local, being found only in the pine-barrens of New Jersey and Nova Scotia. Its fertile one-sided fronds form the most conspicuous part of this tiny plant, the twisting linear sterile fronds being very like grass. See FERNS AND FERN ALLIES

SCHIZOPODA. See CRUSTACEA; OPOSSUM-SHRIMP.

SCHLATTER, shlät'tĕr, **Michael,** American German Reformed clergyman: b. Saint Gall, Switzerland, 14 July 1716; d. near Philadelphia, Pa., November 1790. He was educated at the University of Helmstedt, taught for several years and then entered the German Reformed ministry. He offered his services as a missionary to the German Reformed emigrants in Philadelphia in 1746, and went to Pennsylvania in that year. He served as pastor of the united churches of Germantown and Philadelphia in 1746–51, organized a synod which met in Philadelphia in 1747 and made extended missionary tours through Pennsylvania, Maryland, Virginia, New Jersey and New York. He visited Europe in 1751, secured a much needed reinforcement of six young preachers, substantial aid in the way of money and returned in 1752. As a result of his appeal £20,000 was raised in England and Holland for the establishment of schools among the Germans in America, and in 1755 Schlatter became superintendent of the enterprise, but in 1757 he resigned because of the opposition encountered from the Germans, who objected to the teaching of the English language in the schools. In 1757 he was appointed chaplain of the Royal American regiment, and

remained with the army until 1759. He then preached at Chestnut Hill and surrounding places. In 1777, while still attached to the royal army, he refused to obey orders on account of sympathy with the colonial cause and was imprisoned. Consult Harbaugh, Henry, 'Life of Rev. Michael Schlatter' (1857).

SCHLEGEL, shlā'gĕl, **August Wilhelm von,** German critic, poet and translator: b. Hanover, 5 Sept. 1767; d. Bonn, 12 May 1845. At the University of Göttingen he received a thorough philological training under Heyne and became an admirer and friend of Bürger, with whom he was engaged in an ardent study of Dante, Petrarch and Shakespeare. From 1791 to 1795 he was tutor in a Dutch family at Amsterdam. Soon after his return to Germany he settled in Jena (1796), following an invitation of Schiller. His critical contributions to Schiller's *Horen* and to the *Jenaer Allgemeine Litteratur-Zeitung,* together with his translations from Dante and Shakespeare, established his literary reputation and gained for him a professorship at the University of Jena (1798). His house became the intellectual headquarters of the "romanticists," and was visited at various times between 1796 to 1801 by Fichte, Friedrich Schlegel, Schelling, Tieck, Novalis and others. From 1798 to 1800 he and his brother Friedrich edited the *Athenæum,* a periodical intended to express the "romantic" view of life and literature. In 1801 he went to Berlin, where he lectured before distinguished audiences on the æsthetic and philosophical creed of the romanticists. In 1804 he began to accompany Mme. de Staël, as tutor to her sons and adviser in her literary work, on her extended travels in Switzerland, France, Italy, England and Scandinavia. Mme. de Staël's book 'De l'Allemagne' shows distinct traces of his influence. In 1808 he was in Vienna and delivered his celebrated 'Vorlesungen über dramatische Kunst und Literatur' (pub. 1809–11). In 1813–17 he acted as secretary to the crown prince of Sweden, after which he joined again the household of Mme. de Staël until her death in 1817. In 1818 he became professor at the University of Bonn. He founded a special printing office for Sanskrit and edited several old Indian texts. As an Orientalist he was unable to adapt himself to the new methods opened by Bopp. As a critic he carried on the tradition of Lessing and Herder. Without possessing Lessing's power of style and personality he commanded a wider range of artistic susceptibility. His unerring linguistic and historical scholarship and the calm objectivity of his judgment enabled him to carry out, even more successfully than Herder himself, Herder's demand that literary criticism should be based on a sympathetic penetration into the specific individuality of each poetic production rather than on the application of preconceived æsthetic standards. He established models for the new method of analytical and interpretative criticism in his essavs on Goethe's 'Hermann and Dorothea' and on Shakespeare's 'Romeo and Juliet.' His Vienna lectures 'On Dramatic Art and Literature' were translated into most of the languages of Europe and stand as a permanent contribution to critical literature; his definition of the terms "classic" and "romantic" met with general recognition; his views on the so-called "three unities" and on the "correctness" of Shakespeare evoked an especially strong echo in England and finally made the Johnsonian attitude toward Shakespeare appear obsolete.

Formal perfection of language is the chief merit of his poems, which suffer from a lack of originality. In his drama 'Ion' (1803) he vainly attempted to rival Goethe's 'Iphigenie.' He prided himself on being "model and master in the art of sonnets" among the Germans. He is at his best in sparkling literature parodies such as 'Ehrenpforte und Triumphbogen für Kotzebue' (1801).

His universal receptivity for poetical values, together with his rare facility of linguistic expression, predestined him to be a translator of the first order. His translations from Shakespeare were his greatest artistic contribution to German literature. It is due to him that Shakespeare is hardly less known in Germany than he is in England. Only 17 plays of the so-called Schlegel-Tieck Shakespeare were translated by Schlegel (1797–1810); the remainder were added, from 1825 to 1833, by Graf Wolf Baudissin and (very inadequately) by Dorothea Tieck, while Tieck himself acted only as a reviser and annotator. Schlegel also translated parts of Dante's 'Divina Commedia' (1791–97). His 'Blumensträusse, italiänischer, spanischer und portugiesischer Poesie' (1804) included Petrarca's sonnets. The two volumes of 'Spanisches Theater' (1803–09) introduced five plays of Calderon into German literature. His theoretical essays on the art of translating have guided several generations of German translators. His breadth of culture made him truly a "cosmopolitan of art and poetry." As a critic and as a translator he has lastingly contributed to the realization of Goethe's idea of a "Welt-Literatur."

His first wife, Caroline Michaelis (1763–1809), whom he married in 1796, was the widow of Dr. Böhmer. She was the most brilliant among the "romantic" women. She assisted Schlegel in some of his literary productions, and the publication of her correspondence in 1871 established for her a posthumous reputation as probably the greatest of German letter-writers. She separated from Schlegel in 1801 and became the wife of the young philosopher, Schelling, soon after.

Bibliography.— Schlegel's 'Sämtliche Werke' have been edited in 12 volumes by E. Böcking (1846); 'Vorlesungen über schöne Literatur und Kunst' (ed. by Minor, 3 vols., 1884); 'Œuvres écrites en français' (3 vols., 1846). Consult Strauss, D. Fr., 'Kleine Schriften' (1862); Haym, R., 'Die romantische Schule' (1870; new ed., 1914); Huch, Ricarda, 'Blütezeit der Romantik' (1899); 'Caroline, Briefe aus der Frühromantik' (ed. by Erich Schmidt, 2 vols., 1913); Sidgwick, Mrs. Alfred, 'Caroline Schlegel and her Friends' (1889); Bernays, M., 'Zur Entstehungsgeschichte des Schlegelschen Shakespeare' (1872); Genée, R., 'A. W. Schlegel und Shakespeare' (1903); Gundolf, F., 'Shakespeare und der deutsche Geist' (1911); Helmholtz, A. A., 'The Indebtedness of S. T. Coleridge to A. W. Schlegel' (1907).

TRAUGOTT BÖHME.

SCHLEGEL, Karl Wilhelm Friedrich von, German critic and philosophical writer,

brother of A. W. Schlegel: b. Hanover, 10 March 1772; d. 11 Jan. 1829. As a student at Göttingen and Leipzig he was a voracious reader, especially of the classics. In his earliest publications, including the important essays 'Von den Schulen der griechischen Poesie' (1794); 'Über die Diotima' (1795); 'Über das Studium der griechischen Poesie' (1797), he appeared as a brilliant classical scholar and as an ardent worshipper of the objective harmony of "pure Hellenism." His unfinished 'Geschichte der Poesie der Griechen und Römer' (1798) had a lasting influence on the modern conception of the æsthetic values of Homer. But Schiller's distinction of two separate artistic types (the "naïve" and the "sentimental"), together with the consciousness of his own disharmonious self, caused him to discard his "graecomania." In Jena and in Berlin, where he alternately resided between 1796 and 1802, he was deeply influenced by Fichte, Schleiermacher and Schelling. During this period he wrote his essay 'On Goethe's Wilhelm Meister' (1798), his 'Gespräch über die Poesie' (1800) and a great mass of aphorisms, published as 'Fragmente' and 'Ideen.' Most of these works appeared in the *Athenæum,* which he conducted conjointly with his brother from 1798 to 1800. They are now generally recognized as the deepest and most significant expressions of the subjective idealism of the early romanticists. Most of their peculiar catchwords have been created by F. Schlegel. To him, religion is identical with "Bildung," with the free and endless cultivation of each man's individuality toward the "divine centre." "Romantic poetry" should be "progressive Universalpoesie"; it should give, in endless progression, intimations of the infinite through earthly symbols. "Romantic irony" is the necessary state of mind that enables us to recognize the appearances of life and poetry as mere "allegories" of infinite meanings. F. Schlegel was extremely fertile in discovering and illuminating new problems in the psychology of art, literature and ethics, so that he has been frequently called the forerunner of Nietzsche. But his mystical and paradoxical terminology made these "fragments" almost unintelligible to the general public, until Wilhelm Schlegel simplified and systematized his brother's ideas in his Berlin and Vienna lectures. Friedrich's eccentric novel, 'Lucinde' (1799), in which he extolled the union of sensual and spiritual love as an allegory of the divine cosmic Eros, caused a great scandal by its manifest autobiographical character, and contributed to the failure of his academic career in Jena. In 1802 he went to Paris, where he edited a monthly periodical, *Europa,* and began the study of Sanskrit. His book 'Über die Sprache und Weisheit der Indier' (1803) was the first scholarly treatment of its subject. After having embraced the Catholic faith he went to Vienna (1808), where he was employed in several official and diplomatic positions. Having gained the confidence of Metternich he secured the appointment as Austrian counsellor of legation at the Diet of Frankfort (1815). In 1818 he was again at Vienna. His later works, including 'Geschichte der alten und neueren Literatur' (1815), 'Philosophie des Lebens' (1828) and 'Philosophie der Geschichte' (1829) show an increasingly dogmatic standpoint in religious questions and reactionary tendencies in politics.

His wife, Dorothea (1763–1839), was the daughter of Moses Mendelssohn, the Jewish philosopher. In 1798 she left her first husband, the banker Veit, in order to become F. Schlegel's devoted "comrade" and literary helpmate. She published the products of her own pen, including the novel 'Florentin' (1801), under her husband's name; her adaptations of 'Merlin the Magician' (1804) and of 'Loher and Maller' (1805) have been included in Bohn's English edition of Schlegel's collected works. The 'Sämtliche Werke,' published in 15 volumes (1846), excluded the most important works of his pre-Parisian period. His 'Prosaische Jugendschriften,' on which his fame now rests almost entirely, were collected in two volumes by J. Minor (1882). Good selections ('Fragmente') were edited by E. von der Leyen (1904); 'Briefe an seinen Bruder Wilhelm,' ed. by Walzel (1890); Haym, R., 'Die romantische Schule' (1870; new ed., 1914); Wernaer, R. M., 'Romanticism' (1910); Joachimi, 'Die Weltanschauung der Romantik' (1905); Rouge, J., 'Frédéric Schlegel et la genèse du romantisme allemand' (1904); Enders, C., 'F. Schlegel' (1913).

Traugott Böhme,
Professor of Greek and History.

SCHLEICHER, shlī'hêr, **August,** German philologist: b. Meiningen, 19 Feb. 1821; d. Jena, 6 Dec. 1868. He devoted himself to the study of theology and Oriental languages, first at Leipzig and afterward at Tübingen. In 1846 he took the degree of doctor of philosophy at Bonn, and soon after qualified himself as a teacher of philology, to which he ever after devoted himself. In 1850 he was called to Prague as extraordinary professor of philology, a chair soon exchanged for that of comparative philology. At Prague he made himself more fully acquainted with the Slavonic languages and undertook a several months' journey to Lithuania in order to learn the Lithuanian language. In 1857 he accepted the appointment of honorary professor of the science of language and Old German philology in the University of Jena, where he continued until his death. He published a work on the comparative history of languages, 'Zur vergleichenden Sprachengeschichte' (1848), and another containing a systematic review of the European languages, 'Die Sprachen Europas' (1850). Later works are 'Die Formenlehre der kirchenslawonischen Sprache, erklärend und vergleichend dargestellt' (1853); 'Handbuch der litauischen Sprache' (1856–57). 'Zur Morphologie der Sprache'; 'Die deutsche Sprache' (1860); 'Kompendium der vergleichenden Grammatik der indogermanischen Sprachen'; 'Die Darwinische Theorie und die Sprachwissenschaft'; 'Ueber die Bedeutung der Sprache für die Naturgeschichte des Menschen' (1865).

SCHLEIDEN, shlī'dĕn, **Matthias Jakob,** German botanist: b. Hamburg, 5 April 1804; d. Frankfort, 23 June 1881. He was educated for the law in Heidelberg, but in 1833 took up the study of botany. He occupied the chair of botany at Jena from 1839 to 1863, when he was called to the Botanical Gardens at Dorpt. He was one of the first botanists to study plant

tissue, and his name is associated with that of Nageli, the Swiss botanist, in the early development of the cell theory. His works include 'Grundzüge der wissenschaftlichen Botanik' (1842–43; trans. into English as 'Principles of Scientific Botany,' 1849); 'Die Pflanze und ihr Leben' (1848); 'Baum und Wald' (1870); 'Die Rose' (1873).

SCHLEIERMACHER, shlī'ĕr-mäk'ĕr, **Friedrich Ernst Daniel,** German theologian and philosopher: b. Breslau, 21 Nov. 1768; d. Berlin, 12 Feb. 1834. He was educated by the Moravian Brethren at Niesky. In 1787 he began at Barby the study of theology, which he continued at Halle. In 1794 he was ordained and appointed assistant preacher at Landsberg on the Warthe. From 1796 to 1802 he was chaplain in the Charité-Haus at Berlin. During this period he translated some of Plato's Dialogues, contributed to the *Athenæum* conducted by the two Schlegels, and wrote the 'Discourses on Religion,' the 'Monologues' and 'Letters of a Minister out of Berlin.' In 1802 he published his first collection of sermons, which was followed by two others. In 1802 he removed to Stolpe, where he wrote his 'Critical View of Ethics.' In 1804 he was appointed extraordinary professor of theology at Halle. In 1807, when Halle was separated from Prussia, he went to Berlin and lectured there as well as preached. In 1809 he was appointed preacher at the Trinity Church in Berlin. With Fichte and W. von Humboldt he took a prominent part in the founding of the University of Berlin (1810) and remained, until his death, one of its most distinguished and successful professors. In 1811 he was elected a member of the Academy of Sciences and in 1814 secretary of the philosophical class. His liberal political activity and also his advocacy of doctrinal liberty as a basis of union between the Lutheran and Reformed churches procured him the disfavor of the Prussian government. As a preacher and writer he attracted a large and influential following, especially among the cultured classes, through the eloquent beauty of his style, through his broad interest in the intellectual and artistic movements of his time and through a rare combination of deep religious feeling with critical freedom toward traditional dogmas and conventional morality.

His 'Discourses on Religion, addressed to the educated among its despisers' (1799), show him under the influence both of Spinoza's pantheism and of Kant's criticism. Dissatisfied with the popular rationalistic theology of his times no less than with Kant's moralistic interpretation of religion, he assigns to religion a special province of the human soul, conceiving it to differ essentially from the intellectual and ethical sphere of our mind. Religion, therefore, is neither knowledge nor practice, but a state of feeling, an elevating tone of the whole mind. One of the main characteristics of religious experience is the feeling of being one with the All, the sentiment of an all-embracing and all-absorbing life. This «intuition (Anschauung) and feeling of the universe» does not imply any specific religious creed, not even the belief in a personal God or in the immortality of the soul. It merely establishes an emotional relation of oneness between the individual and the All; the finite self feels its absolute dependence upon the infinite. But this cosmic emotion constitutes, according to Schleiermacher, only one manifestation of religious sentiment; its equally important counterpart is the «self-intuition» and «self-determination» of a man's own «eternal self.» Thus he reasserts the value of human personality, which had been somewhat neglected in Kant's system.

In his 'Monologues' (1800) he assimilates, from the monadology of Leibniz, the idea that each individual is an independent mirror of mankind as a whole and is destined to realize within itself the common ideal in an individual example. Each one should represent mankind in his own way, that is the first principle of morality. But the individual comes to life only in the whole. Thus Schleiermacher, contrary to Kant's ethical formalism, attaches great importance to the actual contents and results of morality, to existing institutions of culture and morality such as the family, society, church, state, arts, sciences, historical religions. The establishment of a higher order of things through the combined individual effort of human beings in human society becomes the central idea of his religious ethics. In his later writings, especially in his 'Christian Morality' and 'Christian Faith' the free philosophical religiousness of his 'Discourse' and 'Monologues' gave way to a more definite appreciation of the historical or «positive» religions and their consummation in Christianity. He find in the person of its founder a living presentation of the endless process at the end of which appears the union of the divine and the human. By such interpretation he is enabled to adopt the Christian Church as a gradual realization in practice of the divine order of things, of the Civitas Dei. All positive affirmations with reference to the Deity he held to be figurative and anthropomorphic. In his 'Life of Jesus,' which anticipated that of D. F. Strauss in important respects, he appears as one of the first representatives of the critical school of Biblical research. His 'Dialektik' assumes the identity of thinking and being as the indispensable presupposition of all knowledge. His works on psychology, on æsthetics, on pedagogy have recently won renewed attention. Schleiermacher occupies a unique position as a representative alike of philosophy and theology. Practically all the modern endeavors to investigate the function of religion in the life of the human soul can be traced back to Schleiermacher. He is generally regarded as the greatest theologian of the Protestant Church since the time of the Reformation. His works have been published in three series entitled 'Theology' (11 vols.), 'Sermons' (10 vols.), 'Philosophical and miscellaneous writings' (9 vols.), Berlin 1836–65. Otto Braun edited an excellent critical selection from his works in four volumes (1910–13). The 'Discourses' and the 'Monologues' have been published in separate editions. Consult Dilthey, 'Leben Schleiermachers' (1870); 'Schleiermacher's Life, as unfolded in his Autobiography and Letters' (tr. by T. Rowan, London 1860, 2 vols.); Bender, W., 'Schleiermachers' Theologie' (2 vols., 1876–78); Lichtenberger, 'History of German Theology in the 19th Century' (1889); Pfleiderer, 'Protestant Theology in Germany since Kant' (1890); Troeltsch et al., 'Schleiermacher, der Philosoph des Glaubens' (1910); Cramaussel, 'La philosophie religieuse de Schleiermacher' (1908);

Siegmund-Schultze, 'Schleiermacher's Psychologie' (1913).

TRAUGOTT BÖHME.

SCHLESINGER, slĕs'ĭn-jĕr, **Frank,** American astronomer: b. New York, 11 May 1871. He was graduated at the College of the City of New York in 1890 and took his Ph.D. at Columbia in 1898. He was an observer in charge of the International Latitude Observatory, Ukiah, Calif., 1899–1903; astronomer Yerkes Observatory 1903–05; director Allegheny Observatory 1905–20; director Yale University Observatory from 1920–41. He was a member of various scientific societies and wrote numerous papers on variations of latitude, spectroscopic binaries, stellar parallaxes, etc. Died, Lyme, Conn., 10 July 1943.

SCHLESWIG, shlāz'vĭg, Germany, a seaport in the province of Schleswig-Holstein, Prussia, at the head of the Schlei, 29 miles northwest of Kiel. It resembles a Dutch town in point of architecture and is divided into three parts — the Alstadt, or Old Town, the Lollfuss and the Friedrichsberg. The only square is the market-place in the Altstadt. The principal street, two miles long, is the Lollfuss. The buildings of importance are the three churches, of which the cathedral (12th century) is a fine Gothic pile, with a tower 368 feet high. Other buildings are the old castle, various benevolent institutions and the Convent for Noble Women. At the south are the remains of a wall erected by pagan kings against the invasion of Jutlanders. As early as the 9th century the city was a great mart for exchange of goods between the countries of the North Sea and those of the Baltic. The chief manufactures are woolen goods, laces, sugar, earthenware and leather. There are seven annual fairs. Pop. 19,905.

SCHLESWIG-HOLSTEIN, shlāz'vĭg-hōl'stīn, a former maritime province of Prussia, between Denmark on the north; the Baltic, Lübeck and Mecklenburg on the east; Mecklenburg and the territory of Hamburg on the south; Hanover southwest and the North Sea on the west. It covers an area of 5,818 square miles. Schleswig is separated from Holstein by the Eider and the Schleswig-Holstein Canal. The province includes several islands in the Baltic and North seas and belongs to the great North German plain. Heligoland belongs to the province. The hilly district on the eastern coast contains the most productive land in the province; the central part is nearly barren, the western coast is protected by many dikes, and is fertile. The Baltic Coast, about 300 miles long, is hilly and contains numerous fjords which make excellent harbors. The North Sea Coast is low and flat. The Elbe forms the boundary on the south for 65 miles. The Eider is the principal river. Other rivers are the Trave and Stor. There are numerous lakes in the northeast, chief of which are Witten-See and Gotteslogs-See. The chief occupations of the inhabitants are agriculture and stock-raising. The majority of the occupants of Schleswig are Danish; of Holstein, German. The industrial works include sugar refineries, breweries and distilleries. The principal ports are Altona, Heligoland, Kiel, Flensburg, Neumühlen, Wyck and Tonning, and the capital, Schleswig. The province became a united duchy in 1386. By the Treaty of Prague, North Schleswig was to choose between Denmark and Prussia, but the privilege was ignored. Its history is a record of continuous strife between Danes and Germans, closing in favor of the latter. The united government of Holstein and Schleswig was first recognized by Margaret of Denmark in 1386, and the basis of this union was the Succession Act, and the practical contradiction between their feudal duty and their own inseparable connection gave rise to the celebrated "Schleswig-Holstein question," causing interminable separations and fusions. By the protocol of 1850 England, France, Austria, Russia, Sweden and Denmark settled, as far as diplomacy could, the much-discussed and difficult question of the duchies of Schleswig and Holstein in favor of Denmark. The unity of Denmark, Schleswig, Holstein and Lauenburg was secured by a uniform law of succession, and as far as was practicable their internal affairs were placed under a common administration. The protocol was succeeded by the treaty of 1852, which historians call "its logical consequence." This treaty assigned the succession to the kingdom of Denmark and the duchies to Prince Christian of Glücksburg, and declared the integrity of the whole Danish monarchy to be permanent; but the rights of the German Confederation with regard to Holstein and Schleswig were "reserved." The declaration was made in accordance with the views of France, Russia and England; the reservation was inserted in the interest of the German powers. It was under this protocol and its succeeding treaty that Denmark expected the aid of England when, in 1864, Austria joined with Prussia to overthrow the treaty and seize Schleswig-Holstein. England called a conference of the signatory powers and attempted by peaceful means to put an end to the war. To quote a modern historian in 'The Historians' History of the World,' "English diplomacy had made every effort imaginable to save the London Protocol and the integrity of the Danish State; but the sole price at which Napoleon III conjointly with England would venture on the strife, the conquest of the left bank of the Rhine, seemed too high, and so it satisfied itself with inviting the subscribers of the protocol to a conference in London. The latter met for no other purpose than the rupture of the protocol, from which the German powers also detached themselves, and to confirm the overthrow of the Danish State, which at the close of the diplomatic tournament saw itself thrown on its own resources. The first notable encounter between British and German warships after the opening of the World War occurred off Heligoland on 28 Aug. 1914.

The Treaty of Versailles of 1919 made provision for settling the ultimate fate of this province by plebiscite. For this purpose Schleswig was divided into two zones. The plebiscite was held in March 1920, when the vote in the northern zone was in favor of incorporation with Denmark, that in the southern was for remaining in Germany. The possession of Holstein, of course, was not in question. The result was a loss of 1,535 square miles of the province to Germany. Pop. of province and Heligoland, 1,519,365. See DENMARK.

SCHLEY, slī, **Winfield Scott,** American naval officer: b. near Frederick, Md., 9 Oct.

1839; d. New York, 3 Oct. 1911. He was graduated at the United States Naval Academy in 1860 and went as midshipman on the *Niagara* to China and Japan. Returning in 1861, he was made master, served on the *Winona* in the West Gulf blockading squadron, later on the *Monongahela* and the *Richmond,* and participated in all the engagements which led to the capture of Port Hudson in 1863, having been promoted to the rank of lieutenant in 1862. Ordered from Southern waters in 1864 to the Pacific squadron, he served on the *Wateree* as executive officer till 1866, when he was promoted lieutenant-commander. In this period he suppressed an insurrection of Chinese coolies on the Chincha Islands, and for protection of United States interests landed a body of men at San Salvador during a revolution. From 1866 to 1869 he was instructor at the Naval Academy; then, being assigned to the Asiatic station, served there on the *Benicia* for three years, earning distinction at the taking of the Korean forts on the Salee River in 1871. Again, in 1872, he was detailed as instructor at the Naval Academy, and in 1874 was made commander. After serving in Europe and on the west coast of Africa, he commanded the *Essex,* on the Brazil station, 1876–79. He was selected to command the third government relief expedition (1884) for the rescue of Lieut. A. W. Greely (q.v.), which he promptly accomplished. Having served (1885–89) as chief of the Bureau of Recruiting and Equipment, he was promoted captain in 1888. From 1889 to 1891 he was in the southern Pacific as commander of the cruiser *Baltimore,* and in the latter year interposed at Valparaiso, Chile, when American sailors were assaulted in the streets.

In 1895 he was placed in command of the *New York;* was chairman of the Lighthouse Board 1897–98; in February of the last-named year became commodore, and after the outbreak of the war with Spain was given command of the Flying Squadron. Sailing from Hampton Roads, 13 May 1898, he began the historic search for Cervera's Spanish fleet, discovered it and finally established a blockade of the harbor at Santiago de Cuba (see UNITED STATES — WAR WITH SPAIN), where, on 29 May, Cervera was found to be. Schley's squadron was united 1 June with the fleet under acting Rear-Admiral W. T. Sampson (q.v.) and the blockade was continued until 3 July, when the Spanish ships came out of the harbor and were destroyed by the American vessels, which, during the temporary absence of Sampson, were under the immediate command of Commodore Schley, on board the *Brooklyn.* In August 1898 Schley was raised to the rank of rear-admiral.

An unfortunate controversy arose between partisans of Schley and those of Sampson over their respective claims to the credit of this great victory. Of that discussion neither officer personally took public notice until after the appearance of a work by Edgar Stanton Maclay (q.v.), entitled 'History of the United States Navy,' in which the author referred to Commodore Schley as a "caitiff, poltroon and coward." The proofs of the book had been read and approved by various naval officers, among them Rear-Admiral Sampson; and on 22 July 1901 Schley applied to the Secretary of the Navy for a court of inquiry. This request was granted 24 July. The court was convened 12 September and its sessions continued for one month. It consisted of Admiral Dewey, president, and Rear-Admirals Benham and Ramsey. The verdict, returned 14 Dec. 1901, was a disagreement, Admiral Dewey refusing to subscribe to censures on Schley's conduct which were made by the two other members. The "majority" report, signed by two members only, found Schley guilty of vacillation, lack of enterprise and disobedience, and in other particulars strongly criticised his conduct, both before and during the battle of Santiago de Cuba, while recognizing his personal courage in the action. Admiral Dewey, however, presented a "minority" report, in which he praised Schley for promptness and efficient service, and gave him the credit for the destruction of Cervera's fleet. Schley filed with the Secretary of the Navy objections to the "majority" report, but it was nevertheless approved by Secretary Long, 20 Dec. 1901. In January 1902, Rear-Admiral Schley appealed from the verdict to the President, who, however, confirmed Secretary Long's approval. On recommendation of the court, no action was taken upon its findings. Schley's retirement from active service at the age limit occurred 9 Oct. 1901. In collaboration with J. R. Soley (q.v.), he wrote 'The Rescue of Greely' (1886); he also wrote 'Forty-five Years under the Flag' (1904).

SCHLICH, shlĭk, SIR **William,** English forester: b. Darmstadt, 1840; d. 25 Sept. 1925. He was educated at Darmstadt and Giessen and was appointed in 1866 to the Indian forest department. He held the offices of conservator of forests, 1871, and inspector-general of forests, 1881; and organized the first school of forestry in England, at Cooper's Hill, in 1885. He was made F.R.S. in 1901 and knighted in 1909. He is the author of 'A Manual of Forestry' (5 vols., 1889–96); 'The Outlook of the World's Timber Supply'; 'Afforestation in Great Britain and Ireland'; 'Forestry in the United Kingdom.'

SCHLIEMANN, shlē'män, **Heinrich,** German archæologist: b. Neubuckow (Mecklenburg-Schwerin), 6 Jan. 1822; d. Naples, 27 Dec. 1890. He spent five years as a pupil in retail business in Fürstenberg, then embarked as cabin-boy on board a ship bound for Venezuela. The ship was wrecked on the coast of Texel, but Schliemann was saved and taken to Amsterdam. Here he obtained a post in a commercial house and set himself to acquire a thorough knowledge of the chief European languages. In 1846 he was sent to Saint Petersburg as agent for another Amsterdam firm. In 1850 he happened to be in California on 4 July when the State entered the Union and acquired American citizenship. By 1856 he had learned modern Greek and begun the study of ancient Greek, and in 1858–59 traveled in Sweden, Denmark, Germany, Italy, Egypt, Syria and Greece. Having amassed a considerable fortune in trade, he retired from it in 1864 in order to devote himself wholly to archæological studies. He traveled round the world in 1864–66, and in 1868 went to the coast of Asia Minor by way of Corfu and the Morea. In 1870 he undertook at his own cost the excavation of the heaps of ruins at Hessarlik, in the Troad, which he believed to be the site of ancient Troy

(q.v.). These excavations he carried on with interruptions until 1890. Contrary to agreement with the Porte, he retained possession of all the spoils discovered there, and was compelled by the Greek courts to pay the sum of $10,000. He presented his collections to the Museum für Völkerkunde at Berlin. In 1876 he began similar excavations at the site of ancient Mycenæ in Greece. Little confidence was at first placed in his methods by trained archæologists, and when his discoveries had been made their historical value was for a time doubted. But scholars now generally agree that they attest powers adequate to the Trojan War, and make the traditional account probable in its main outlines. Consult his autobiography edited by his wife (Leipzig 1891); Schuchardt, 'Schliemann's Excavations and Archæological and Historical Studies' (London 1891); Sandys, J. E., 'A History of Classical Scholarship' (Cambridge 1908); Hawes, C. H. and H., 'Crete: the Forerunner of Greece' (London 1909).

SCHLOSSER, shlŏs'sĕr, **Friedrich Christoph,** German historian: b. Jever, Oldenburg, 18 Nov. 1776; d. Heidelberg, 23 Sept. 1861. He studied at the University of Göttingen 1794–98, and published his first history, 'Geschichte der bildersturmenden Kaiser des Oström' in 1812. He was professor in the Lyceum of Frankfort 1812–14 and city librarian until 1819, when he was called to Heidelberg as professor of history at the university, a position retained until his death. Schlosser's writings, which are characterized by a great love of truth and a high moral tone in judgment, include 'Weltgeschichte in zusammenhängender Erzählung' (1817–24); 'Geschichte des 18. Jahrhunderts' (1823); 'Universal-historische Uebersicht der Geschichte der alten Welt und ihre Kultur' (1824–34).

SCHLUNDT, shlŭnt, **Herman,** American chemist: b. Two Rivers, Wis., 16 July 1869. He was graduated at the University of Wisconsin in 1894 and took his Ph.D. at the University of Leipzig in 1901. He was for a time connected with the faculty at the University of Wisconsin, and from 1902 was associated with that of the University of Missouri, where he was professor of physical chemistry from 1907, and chairman of the department of chemistry in 1910–15. He is author of numerous articles on physical chemistry and radio-activity and of 'Laboratory Experiments in General Chemistry' (1912).

SCHLUTER, shloo'tĕr, **Andreas,** German sculptor and architect: b. Hamburg, 20 May 1664; d. Saint Petersburg, 1714. His father was a sculptor and brought him in early life to Dantzig. He left that place for Marschau, where he opened a studio as a sculptor and eventually (1694) settled in Berlin. The Baroco style of architecture, then popular in Holland, attracted his fancy and in this style he began (1696) to make designs for rebuilding the royal residences. Before carrying them out he took a journey through Italy, where he built the central front of the castle at Charlottenburg, and subsequently began the restoration of the royal castle at Berlin and became actively engaged in designing buildings of this class in other parts of the country. He eventually removed to Saint Petersburg and became court architect to Frederick the Great. Among the statues he erected in Berlin are the statue of the grand elector (cast by Jacobi in 1700). Besides the bronze statue of the Grand Elector Frederick III at Königsberg, the tomb of Frederick I and his wife in Berlin and the marble screen in the church of Saint Mary, he produced numerous designs for the gorgeous interior decoration of the Goldsmiths' Hall, Berlin, and other buildings. Consult Adler, 'Andreas Schlüters Leben.'

SCHMALKALDEN, shmäl'käl''dĕn, **Articles of,** a Protestant confession which was drawn up at the instance of John Frederick, Elector of Saxony, by Luther and other divines, and signed at Schmalkalden in February 1537. These articles were essentially the same as those of the Confession of Augsburg, but in much stronger language. See Reformation, The.

SCHMALKALDIC LEAGUE, the league formed at the close of 1530 by the Protestant princes of Germany, assembled at Schmalkalden, to resist the aggressive measures contemplated by the Emperor Charles V. It ultimately included the whole of northern Germany, Saxony, Würtemberg and Denmark, with portions of Bavaria and Switzerland. The object of the league was the common defense of the political and religious freedom of the Protestants, and the confederacy was first intended to continue only for six years, but subsequent events induced them in 1535 to renew it for another period of 10 years, and to raise a permanent army to carry out the objects of the league. About this time it was joined, among others, by the king of France, Francis I, though only from political motives, and Henry VIII of England declared himself its protector. The confederacy received a fuller consolidation by a new Protestant confession, drawn up at the instance of John Frederick of Saxony by Luther and other divines, and known as the Articles of Schmalkalden, from the circumstance of their having been signed (1537), like the league itself, at the town of Schmalkalden. These articles were essentially the same as those of the Confession of Augsburg. The league was latterly crippled by mutual jealousy and the conflict of interests, and its early successes in the so-called Schmalkalden War were ultimately more than outweighed by the complete rout at Mühlberg and the capture of John Frederick. The ends of the league, however, were ultimately gained through the instrumentality of Duke Maurice, now Elector of Saxony, who in 1552 declared war against the emperor, and forced him in 1552 to grant the Treaty of Passau, which secured the religious liberty of the Protestants. See also Charles V; Reformation, The.

SCHMAUK, smâk, **Theodore Emanuel,** American clergyman: b. Lancaster, Pa., 1860; d. 23 Mar. 1920. He was graduated at the University of Pennsylvania in 1880, ordained to the Evangelical Southern ministry in 1883; was editor-in-chief of the *Lutheran Church Review* from 1895; literary editor of the *Lutheran* from 1889; professor of Christian faith in the Lutheran Theological Seminary from 1911 and president of the General Council of Evangelical Lutheran Churches in North America from 1903. He published 'The Negative Criticism of the Old Testament' (1894); 'History of Old Salem and Lebanon' (1898); 'The Early

Churches of the Lebanon Valley (1902); *The History of the Lutheran Church* (1903); *The Confessions and Confessional Principle of the Lutheran Church* (1909); and *Christianity and Christian Union* (1913).

SCHMID, shmĭt, **Matthias,** Austrian painter: b. See, Tirol, Nov. 14, 1835; d. Munich, Jan. 22, 1923. He studied at the Munich Academy (1856) under Johannes von Schraudolph, and was a pupil of Karl von Piloty (1869), when the persecution to which the clergy subjected him on account of his liberal views caused him to leave Tirol. He won the Vienna medal in 1873.

Among his canvases are *The Entombment; The Flight into Egypt; Festival of the Parson's Cook* (1874); *The Betrothal* (1879); *Repairing the Damage* (1882); *Blind Man's Buff* (1884); *Forsaken* (1885); *In the Picture Gallery* (1886). He has also done in fresco at the Innsbruck Cemetery *The Three Marys at Christ's Tomb* (1859).

SCHMID, Ulrich, German historian: b. Niederrieden, Swabia, July 4, 1876. He was educated at the Memmingen Latin School and the Würzburg Gymnasium, the universities of Würzburg, Freiburg-in-Breisgau, Munich, and Vienna. He has devoted much of his time to the study of the history of culture and from 1904 edited *Walhalla* at Munich. He published a number of church histories and biographies and also edited *Das katholische Kirchenjahr in Bildern* (1910), and the religious art series of *Glaube und Kunst* since 1912.

SCHMIDT, shmĭt, **Johannes,** German philologist: b. Prenzlau, July 29, 1843; d. Berlin, July 4, 1901. After study at the University of Bonn he was there made professor (1873), in the same year removed to Grätz, and from 1876 until his death was at Berlin. In 1884 he was elected to the Prussian Academy of Sciences. Probably he was not excelled by any scholar of his time in an extensive scientific knowledge of the grammar of the Indo-German group of languages. In addition to his philological works he edited, from 1875 (with Kuhn), the *Zeitschrift für vergleichende Sprachforschung.*

SCHMIDT, Kaspar, German philosopher, better known under his pseudonym of Max Stirner (q.v.).

SCHMIDT, Nathaniel, American Orientalist: b. Hudiksvall, Sweden, May 22, 1862; d. Ithaca, N. Y., June 30, 1939. He was educated at the universities of Stockholm, Colgate, and Berlin, and was professor of Semitic languages and literatures at Colgate University, 1888–1896, and professor of Semitic languages and Oriental history at Cornell University, 1896–1932; emeritus thereafter. He was director of the American School of Archaeology in Jerusalem, 1904–1905, and later was a member of the board of trustees of the American Schools of Oriental Research in Jerusalem and Baghdad. His published works include *Introduction to the Hexateuch* (1896); *Biblical Criticism and Theological Belief* (1897); *Syllabus of Oriental History* (1897); *The Republic of Man* (1899); *Outlines of a History of Egypt* (1901); *The Prophet of Nazareth,* 2d ed. (1907); *The Messages of the Poets* (1911); *Ibn Khaldun, Historian, Sociologist, Philosopher* (1930); *The Coming Religion* (1930).

SCHMITZ, Eugene F., American politician: b. San Francisco, Aug. 27, 1864; d. San Francisco, Nov. 20, 1928. He was elected mayor of San Francisco on the Union Labor ticket in 1900 and was twice re-elected. In 1907 he, with Abe Ruef (q.v.), was tried on a charge of extortion in connection with the sensational graft scandals then uncovered. He was convicted, but succeeded in having the judgment set aside. Later he again became active politically and he was his party's candidate for mayor in 1915, but was not elected.

SCHMUCKER, shmŭk'ẽr, or **SMUCKER, Samuel Mosheim,** American historical writer: b. New Market, Va., Jan. 12, 1813; d. Philadelphia, Pa., May 12, 1863. He was graduated at Washington College, Pennsylvania, in 1840, and was licensed to preach in the Lutheran Church. In 1848 he resigned his duties as a pastor to study law, was admitted to the bar and practiced for a time in Philadelphia; but after 1855 devoted himself almost wholly to literature. He was the author of numerous biographical and historical books. At his death he had completed one volume of his *History of the Civil War in the United States* (1863).

SCHMUCKER, Samuel Simon, American Lutheran theologian: b. Hagerstown, Md., Feb. 28, 1799; d. July 26, 1873. A graduate of the University of Pennsylvania and Princeton Theological Seminary, he was long a leader of the Lutheran General Synod. As a liberal he opposed the conservatism of the mid-19th century German immigrants, supporting "American" as against "Old" Lutheranism. He published 44 works.

SCHNABEL, shnä'bĕl, **Artur,** Austrian pianist and composer: b. Lipnik, Austria, April 17, 1882; d. Axenstein, Switzerland, Aug. 15, 1951. Schnabel was recognized for his knowledge and interpretation of the works of Beethoven, having recorded every piano concerto and sonata of that great master. At the age of seven he began to study piano; in 1919 he was given an honorary professorship by German governmental decree. His first visit to the United States in 1922 was not a marked success. He returned in 1930 and 1933 and was exceptionally well received. Subsequently he toured the United States many times, his last appearance being in January 1951. Schnabel also toured Egypt and Palestine (1935), Australia (1939), and lectured at the universities of Chicago (1940 and 1945), and Michigan (1943). Aside from the versatility of his piano interpretations of the great masters he was well known for his compositions which included three symphonies, five string quartets, a piano concerto, a violin sonata, and other piano pieces. He also wrote two books: *Reflections on Music* (1936); and the *Line of Most Resistance* (1942).

SCHNAUZER, shnou'zẽr, a dog of the terrier breed which originated in Germany at least 500 years ago and which has remained unchanged in conformation since the earliest recorded description. The Schnauzer is a heavy-set dog, well boned and muscular. The head is fairly long with small V-shaped ears, heavy eyebrows, mustache and beard, and a dense wiry coat, growing against the grain on the back. Color: pepper-and-salt, pure black, or black and tan. There are three varieties of Schnauzer: the miniature, the standard, and the giant. The Schnau-

zer standard is 18 to 20 inches for males and 17 to 19 for females; the miniature Schnauzer should be from 11½ to 13½ inches. Some authorities believe the Schnauzer to be a cross between the Spitz and the Dog of Bologne.

SCHNEIDER, shnī'dėr, **Charles Conrad,** American engineer: b. Apolda, Saxony, 24 April 1843; d. 8 Jan. 1916. He was graduated at the Royal Technical School, Chemnitz, Germany, in 1864, came to the United States in 1897 and engaged in locomotive and bridge construction. He was vice-president of the American Bridge Company in 1900–03 and in 1911 became a member of the board of engineers for the Quebec bridge. Among the many bridges he designed and built are the cantilever Fraser River bridge on the Canadian Pacific Railway, and the Niagara cantilever bridge. In 1905 he was president of the American Society of Civil Engineers. Author of 'General Specifications for Railroad Bridges' (1886); 'General Specifications for Highway Bridges' (1901); 'General Specifications for Structural Steel Work in Buildings' (1905; new ed., 1910).

SCHNEIDER PROCESS OF ARMOR PLATE. See Armor Plate.

SCHNITZER, shnĭt'sĕr, **Edward.** See Emin Pasha.

SCHNITZLER, Arthur, Austrian dramatist and novelist: b. Vienna, 15 May 1862 (the son of the well-known laryngologist, Professor Johann Schnitzler, (1835–93); d. Vienna, 21 Oct. 1931. He studied medicine at the University of Vienna, receiving his degree in 1885, was interne in the Vienna General Hospital from 1886 to 1888, and then became an assistant at the Vienna Polyclinic as well as a private general practitioner. In judging the general tone, style and choice of subject of the Viennese writers of Schnitzler's generation it is important to remember that they differ from their Berlin contemporaries in that the former are more affiliated, in the emulation of their models, with French and Italian writers, while the latter incline more to an imitation of the Russians and Scandinavians. This means greater perfection of form and style among the Viennese, greater depth of treatment and recognition of the social milieu among the Berliners. Schnitzler and Gerhart Hauptmann may well be regarded as typical representatives of their respective cities in the same generation. 'Anatol' (Berlin 1892), Schnitzler's first publication, was typical of almost all his later work. It was a series of seven dramatic scenes, each depicting, in delicate psychological treatment, a different phase in the rather frivolous love-life of the hero. 'Liebelei' (1896) is a drama depicting love in a more tragic aspect. 'Der grüne Kakadu' (1899), was played by Mrs. Fiske in New York as 'The Green Cockatoo,' as a «curtain-raiser» to Hauptmann's 'Hannele'; it was a one-act play of powerful dramatic construction, dealing with a superficial episode of the French Revolution. His later plays became more mystical and resigned in tendency, although the erotic undercurrent is absent only in one play ('Professor Bernhardi,' see below): 'Paracelsus' (1899), 'Der Schleier der Beatrice' (1901), 'Lebendige Stunden' (1902), 'Der einsame Weg' (1903), 'Der Ruf des Lebens' (1905), 'Comtesse Mizzi' (1909), 'Der junge Medardus' (1910), 'Das weite Land' (1911). 'Professor Bernhardi' (1913) is a serious comedy, a satirical presentation of Austrian political intrigue, in which great issues are made to depend on trifling happenings. Only one female character appears in the play, a hospital nurse, who drops from view as soon as she has started the mischief. The treatment of anti-Semitic tendencies in ousting a Jewish hospital-director from his position because he has come into conflict with the interests of the ruling church receives added interest from the fact that Schnitzler was himself by birth a Jew and by training a physician, and it was not unlikely that the subject was taken from one of his own experiences. In 1915 Schnitzler published 'Komödie der Worte,' three one-act plays, in which he showed, by again resorting to erotic subjects, that the war in Europe has not always been successful in turning men's minds to serious topics. Among the best short stories were 'Sterben' (1895), 'Die Frau des Weisen' (1898), 'Leutnant Gustl' (1901), 'Die griechische Tänzerin' (1904), 'Der Tod des Junggesellen.' There were also two longer narratives (the second a long novel): 'Frau Bertha Garlan' (1901), 'Der Weg ins Freie' (1908). Later works are 'Casanova's Homecoming' (tr. 1921 and 1930), 'Dr. Graesler' (New York 1921), 'Road to the Open' (New York 1923), 'The Shepherd's Pipe' (New York 1923), 'Beatrice' (New York 1926), 'Fraulein Else' (New York 1925), 'None but the Brave' (New York 1926), 'Rhapsody' (New York 1927), 'Lonely Way' (Boston 1922). Schnitzler's collected dramas have appeared at Berlin (1910, 4 vols.), as well as the collected narratives (1910, 3 vols.). (See Anatol). A translation of the one-act play 'Literature' will be found in 'The German Classics of the 19th and 20th Centuries' (New York 1914), and a number of other plays have been translated by Edwin Björkman. Consult Hartmann, J. W., 'Schnitzler's Vienna' (*The New Review*, New York, January 1916); Pollard, Percival, 'Masks and Minstrels of New Germany' (Boston 1911); Salkind, Alexander, 'Arthur Schnitzler' (Leipzig 1907); Ratislaw, J. K., 'Arthur Schnitzler' (Hamburg 1911); Kapp, Julius, 'Arthur Schnitzler' (Leipzig 1912).

Jacob Wittmer Hartmann,
Late Head of the Department of German, Long Island University, New York.

SCHNORR VON KAROLSFELD, shnōr fōn kär-ōls-fĕlt, **Julius,** German painter: b. Leipzig, 26 March 1794; d. Dresden, 24 May 1872. His father was a painter and initiated him into the rudiments of art. In 1811 he proceeded to Vienna, and while there produced several works. In 1817 he visited Italy, spent a year at Florence and then took up his residence at Rome. Here he attached himself to the «Nazarenes,» then under the leadership of Cornelius and Overbeck. His painting 'The Wedding in Cana' attracted so much notice that he was chosen, along with the two painters already named, to paint the walls of the Villa Massimi at Rome. Among other works produced by him at Rome are 'Jacob and Rachel'; 'Ruth and Boaz'; 'The Flight into Egypt,' and 'Children brought to Jesus.' He removed to Munich in 1827, and was appointed professor of historical painting in the Academy of

Fine Arts there. He was next commissioned to decorate the new palace with frescoes of scenes from the national poem of the 'Nibelungenlied'; and adorn the Festsaalbau with incidents in the lives of Charlemagne, Frederick Barbarossa and Rudolf of Hapsburg. These are perhaps the most popular of modern works in fresco in Munich. In 1846 he became director of the picture gallery and professor at the Academy of Fine Arts in Dresden. While here he completed his illustrations of the Bible, 'Die Bibel in Bildern' (1852–60). They exhibit wonderful animation, variety and power. To the Dresden period also belong the oil-painting of 'Luther at the Diet of Worms,' and the designs for a window for Saint Paul's, London, representing scenes from the life of Saint Paul.

SCHODDE, George Henry, American scholar: b. Allegheny, Pa., 15 April 1854; d. 15 Sept. 1917. He was graduated from Capital University 1872 and from Leipzig University 1877, was professor of Greek and theology at Capital University, Columbus, Ohio, from 1880, editor of *The Lutheran Standard* from 1880 and of *The Theological Magazine* from 1897. He was also a contributor to the *Independent*, the *Sunday School Times* and a large list of church periodicals. He published 'The Protestant Church in Germany' (1903); and translated 'The Book of Enoch' and 'The Book of Jubilees,' from the Ethiopic, and 'Day in Capernaum' from the German of Delitzsch, Weiss' 'Religion of the New Testament' (1905). Weiss' 'Commentary on the New Testament' (4 vols. 1906), etc.

SCHOEBORN, shė'bôrn, **August,** American architect: b. Germany, about 1827; d. Washington, D. C., 25 Jan. 1902. He came to Wisconsin in 1849, but later removed to Washington, D. C., where until his death he was a member of the staff of the architect of the Capitol. In Civil War time he drafted plans of barracks, hospitals and forts for the quartermaster-general's department, and maps and plans for the use of General McDowell.

SCHOEFFER, shėf'fėr, **Peter,** German printer: b. Gernsheim, near Mainz, about 1430; d. about 1502. At about the age of 20 he was a student at the University of Paris, and a copyist. It seems likely that Gutenberg taught him what he knew of printing and employed him in his establishment at Mainz. After Fust and Gutenberg dissolved partnership Schoeffer was connected with the former, and the two names are associated on the imprint of the 'Book of Psalms,' printed in 1457. The reputation of his being the inventor of matrices and the typemold got abroad during his lifetime and was aided by his own artful insinuations; but modern research has disproved his claim to the work done by Gutenberg. He followed the career of printer after the death of his partner, Fust, and issued many works alone. He was succeeded by three sons who became eminent printers. Consult De Vinne, 'The Invention of Printing' (1876).

SCHOENECK, shėn'ėk, **Edward,** American lawyer: b. Syracuse, N. Y., 1 Aug. 1875. He studied law at Syracuse University and was admitted to the bar in 1903. In 1902 he became a member of the board of supervisors of Onondaga County, was a member of the New York assembly, 1904–07 and mayor of Syracuse, 1910–13. He was elected lieutenant-governor of New York 1915–16 and 1917–18.

SCHOENFELD, Hermann, professor: b. Oppeln, Germany, 21 Jan. 1861; d. 4 July 1926. He was educated in the universities of Berlin, Breslau and Leipzig, and in 1888 accepted a call as instructor in modern languages at Providence, R. I., and later at New Bedford, Mass. In 1891 he was appointed to Johns Hopkins University; in 1893 sent by President Cleveland as consul at Riga, Russia, and delegated by the United States Bureau of Education to investigate higher education in Russian, Austrian and Prussian Poland. Served as Ottoman consul-general at Washington, 1899–1910. After October 1894 he was professor of Germanics at Columbian (now George Washington) University. Dr. Schoenfeld was a contributor to many German and American magazines and encyclopedias, including THE ENCYCLOPEDIA AMERICANA. He published 'Brant and Erasmus' (1892); 'Erasmus and Rabelais' (1893); 'Higher Education in Poland' (1896); 'German Historical Prose' (1896); Leopold von Ranke' (1899); 'Treitschke'; he edited Schiller's 'Maria Stuart' (1899) and 'Wilhelm Tell' (1902); Bismarck's 'Orations and Letters' (1905); 'History of Teutonic Women, and Slavic Women' (1906); 'Essays on Universal Peace and German Armaments' (1913); 'Causes of the European Conflagration' (1914–15). From 1914 he also contributed extensively to journalistic literature on contemporaneous European history, especially of the Slavs and the Near East.

SCHOENLEBER, shėn'lā-bėr, **Gustav,** German painter: b. Bietigheim, Würtemberg, 3 Dec. 1851. He studied under Kurtz in Stuttgart and Adolf Lier in Munich, and traveled in Italy and Holland, in the latter country especially finding congenial themes for his landscape art. He reproduced the tender tints of the flat, moist land with now and then a church steeple or a clump of trees as a diversifying feature. In 1880 he was made professor at Carlsruhe. Among his works are 'Harbor of Genoa' at Rotterdam; 'Venetian Fishing Boats' at Hamburg Gallery; 'View of Flushing at Low Tide' (1881), Dresden Museum; 'Evening near Dordrecht,' Stuttgart Museum. He died in 1917.

SCHOENN, shėn, **Aloys,** Austrian artist: b. Vienna, 11 March 1826; d. Krumpendorf, 16 Sept. 1897. He studied at the Vienna Academy under Führich and Leander Russ. He served through the Italian campaign of 1848 and fought in the Hungarian war. During 1850–51 he studied at Paris, and then traveled in the East. His field is genre. Some of his works are 'Evening on the Nile'; 'Departure of Tyrolese Students from Vienna in 1848'; 'Storming of Ladrone,' 'On the Coast of Genoa,' 'Goose Market at Cracow,' at Vienna; 'Scene in Persecution of Jews'; 'Festival in Capri'; 'Fish Market at Chioggia'; 'Market in Bosnia'; 'Market in Tunis.'

SCHOFIELD, skō'fēld, **John McAllister,** American military officer: b. Gerry, N. Y., 29 Sept. 1831; d. Saint Augustine, Fla., 4 March 1906. He was graduated from West Point in 1853, and assigned to garrison duty in South Carolina and Florida. In 1855–60 he was assistant professor of philosophy at West Point, and was professor of physics in Washington

University, Saint Louis, Mo., in 1860–1861. He acted as mustering officer for the State of Missouri at the outbreak of the Civil War, served on the staff of General Lyon in the Missouri campaign and in November 1861 was appointed brigadier general of volunteers. He was in command of the District of Missouri in 1861–1862, of a division in the Army of the Cumberland in 1863, and again commanded the Department of Missouri in 1863–1864. In 1864–1865 he commanded the Department of the Ohio, was engaged in the Atlanta campaign and commanded at the battle of Franklin, Tenn., in 1864, receiving rank as brigadier general and brevet major general in the regular army in recognition of his services. He continued in the army after the war, was secretary of war in 1868–1869, and commanded various departments until 1888 when he was assigned to the command of the army of the United States as senior major general. In 1895 he was promoted lieutenant general, a grade created for him, and later in the same year he was retired. He published *Forty-six Years in the Army* (1897).

SCHOFIELD, Walter Elmer, American artist: b. Philadelphia, Pa., Sept. 9, 1867. He studied at the Academy of Fine Arts, Philadelphia, and in Paris under Bougereau, Edmond Aman-Jean, Ferrier and Doucet. During a three years' residence at St. Ives he specialized independently in landscape work and notable examples are *Morning* and *Midwinter Thaw* in the Cincinnati Museum, *Across the River* in the Carnegie Institute, Pittsburgh, *Morning after Snow* in the Corcoran Art Gallery, Washington, and *Sand Dunes Near Lelant* in the Metropolitan Museum, New York.

He received many medals and honor awards and was elected National Academician in 1907. In 1915 he enlisted in the British army and received advancement to captain of artillery. He received the Altman Prize in 1920.

SCHOFIELD, William Henry, American educator: b. Brockville, Ontario, April 6, 1870; d. June 24, 1920; graduated at the University of Toronto, 1889, took his Ph.D. at Harvard in 1895, studied at Paris, Christiania and Copenhagen in 1895–1897. He was master of modern languages at Collegiate Institute, Hamilton, Ontario, in 1889–1892. From 1897 he was connected with the faculty at Harvard, and from 1906 he was professor and head of the department of comparative literature there. He was Harvard exchange professor at Berlin in 1907–1908; and was lecturer at the Sorbonne, Paris, and at the University of Copenhagen in 1911.

He was editor in chief of *Harvard Studies in Comparative Literature.* Author of *Studies on the Libeaus Desconus* (1895); *The Home of Eddic Poems* (1899); *English Literature from the Norman Conquest to Chaucer* (1905); *Chivalry in English Literature* (1912); *A Blind Bard from Faery* (1918); and *Life of William Wallace* (1918).

SCHOHARIE, skō-hăr'ĭ, town and village, New York, Schoharie County seat; altitude 611 feet; 37 miles west of Albany. Its industries are dairying, farming, cultivation of nursery stock, stone quarrying, and plastic products.

Old Stone Fort, erected in 1772 as a Dutch Reformed Church, was stockaded for valley defense in 1777, and figured in the revolution. It is now maintained as a county museum. Pop. (1950), town, 2,794; village, 1,063.

SCHOHARIE CREEK, New York, rises in Greene County, and flows 85 miles east and north to the Mohawk River.

SCHOHARIE GRIT, a more or less silicious and calcareous shale, or a silicious limestone typically found in the Schoharie Valley of eastern New York, from which it takes its name. It is intimately associated with the overlying Onondaga limestone of New York, with which together it forms the Ulsterian subgroup of the Mid-Devonic group. At its type location it is not over six feet thick and richly fossiliferous. In the Hudson Valley it is a shale, almost barren and sometimes 100 feet or more in thickness.

SCHOLAR-GIPSY, The, and **THYRSIS.** Matthew Arnold's pastoral idyls, *The Scholar-Gipsy* (1853) and *Thyrsis* (1866) are linked by internal references and, like *L'Allegro* and *Il Penseroso* by similarities of form, mood, scene and theme, both being interpretations of the sentiment of the Cumner country near Oxford as felt by a poetic spirit somewhat ill at ease amid the distractions of his century. The earlier poem was suggested by an incident related in Glanvil's *Vanity of Dogmatizing* (1661) of an Oxford lad who had joined a band of gypsies and had acquired from them a secret for working wonders through the power of imagination. Arnold makes this lad a symbol of the simple-hearted idealism of an elder day, and feigns that his shy spirit still haunts the Cumner hills and appears to shepherds and reapers and village maidens dancing around the Fyfield elm in May—his hands filled with "dark bluebells drench'd with dews of summer eves." Apostrophizing this charming genius loci, the poet bids him shun the feverish contact of men infected with "this strange disease of modern life, with its sick hurry, its divided aims, its heads o'ertax'd, its palsied hearts." *Thyrsis,* the only rival in English to *Lycidas* and *Adonais,* was written ostensibly to commemorate the author's friend, Arthur Hugh Clough, who had died at Florence in 1861; but there is not very much of Clough in the piece. What Arnold really commemorates is the emotion excited by the pastoral loveliness of the scenes in which he and his brother poet, a companion of his college days, spent their dreaming youth, as yet untroubled by the contentions of the workaday world, still pursuing the gleam of a poetic imagination, still free to wander like Sicilian shepherds through "many a dingle on the loved hillside." With one exquisite image after another Arnold evokes the feeling of early spring, the fragrance of whitening hedges, the cuckoo's parting cry, the rapture of young blood in June when the high midsummer pomps come on:

> "Roses that down the valleys shine afar,
> And open jasmine-muffled lattices,
> And groups under the dreaming garden-trees
> And the full moon, and the white evening-star."

Death and the call of the busy world ended this Theocritean holiday and harshened and silenced the music of these young singers, but by the magic of these two poems Arnold and Clough and the nameless Oxford lad will be associated forever, in the minds of all lovers of poetry, with the romance of the "home of lost causes" and the enchantment of the Eng-

lish spring. For periodical criticisms consult Smart, T. B., 'Bibliography of Matthew Arnold' (1892); books on Arnold by Saintsbury, George (1899); Paul, H. D. (1902); Russell, G. W. E. (1904); Dawson, W. H. (1904); Dixon, J. M. (1906); Sherman, S. P. (1917).

STUART P. SHERMAN.

SCHOLASTICISM (Lat. *schola*, "school"). Scholasticism is the philosophy of the "Schools." Charlemagne (742–814), inviting leading scholars of the Church to his court, established a Palatine School and a series of cloister and diocesan schools throughout his empire, and out of these as the mediæval centres of learning arose the scholastic philosophy. The term "scholastic" (Doctor Scholasticus) was applied not only to teachers of the seven liberal arts in these Carolingian institutions and the later established seats of learning, but also to teachers of theology and philosophy. The term gradually became narrowed to denote the latter class. The movement extends from 850 to 1453 A.D. and may be divided into two periods: (1) 850–1200, that is, from Johannes Scotus (or Erigena) to John of Salisbury and the Arabs; (2) 1200–1453, that is, from Alexander of Hales to the fall of Constantinople and the rise of Humanism. The first period is characterized by the controversy on the subject of universals. The second period is marked by the fusion of Aristotelianism with dogmatic theology, the delimitation of the spheres of faith and reason and the controversy regarding the primacy of the will over the intellect. In the first period the chief figures are Johannes Scotus, also called Erigena (that is, Irish-born, b. 810, d. 877, the earliest notable scholastic, fused Neo-Platonism with Christian theology, Gerbert (c. 1003 as Pope Sylvester II and distinguished for investigations in mathematics and natural science), Roscellinus (b. 1050, originator of Nominalism), Peter Lombard (d. 1164 as bishop of Paris, writer of the famous 'Sentences'), William of Champeaux (1070–1121, champion of realism against Abelard), Anselm of Canterbury (1013–1109, constructed an ontological argument for the existence of God), Abelard (1079–1142, originator of Conceptualism), John of Salisbury (1110–80, beginnings of reactionary attitude toward the one-sided scholastic culture). To the second period belong chiefly the following: Alexander of Hales (d. 1245, one of the originators of the 'Summa,' a sort of encyclopedia of theology and natural science, that attained vogue in this period), Bonaventura (1221–74, mystic), Albertus Magnus (Count of Bollstädt, 1193–1280, the most learned man of his age in the natural sciences), Thomas Aquinas (1225–74, fused Aristotelianism with Christian theology), Duns Scotus (1274–1308, advocate of the primacy of the will against the Determinism of the Thomists), William of Occam (1270–1347, important Nominalist and opponent of the temporal power of the papacy). The early schoolmen possessed among other works a meagre part of the logical treatises of Aristotle, Plato's Timæus, the writings of Boethius, Cicero, Seneca, Augustine, Martianus Capella and Pseudo-Dionysius the Areopagite. The latter schoolmen possessed the whole body of Aristotelian writings, and the works of the Arabs and Jews. One of the fundamental characteristics of the scholastic period is the subservience of philosophy to theology. Philosophy is under the rigid censorship of the Church and although the intrinsic spirit of scholastic philosophy may not be that of a "handmaid to theology" (*ancilla theologiæ*), yet ecclesiastical authority reduces it practically to that position. Its real spirit is no doubt the desire to harmonize rational and revealed truth, and not to diminish the claims of reason. Nevertheless, its historical function was not so much the discovery of truth, as the defense of dogma. The service demanded of philosophy is apologetic and, therefore, the discipline of logic is particularly important and widely studied. Knowledge is subordinated to faith. In the scholastic era the Church was the bearer both of science and religion, but as the interests of the latter were the primary concern of the Church and in its estimation the most important for man, the subordination of science to theology was, from the Church's viewpoint, both legitimate and necessary. Gradually, however, science and philosophy asserted their independent claims, and in the Renaissance, the rebirth of the Greek spirit and of the dignity and worth of profane culture,— reason assumed a distinctive position for itself. The result was a long warfare between science and theology, between reason and creed. Although scholasticism was a combination of Hellenic thought with the Church dogmas, yet the rationalistic spirit of Greek philosophy remained practically dormant during the entire scholastic period and did not really awake until the rise of Humanism. The most important question for early scholasticism was the ontological significance of logical genera or universals. In this controversy the scholastics split into two great parties, the realists and nominalists.

Realism is the doctrine that genera and species have existential reality, that is, they are entities, and extreme realists regarded such universals as existing apart from and independent of particulars. The formula for the extreme realists is that universals exist *ante rem* ("before the particular," Platonism); of the moderate realists that they exist *in re* ("in the particular," Aristotelianism). The extreme opposition was formed by the nominalists who maintained that universals or genera are only class names and have no existence apart from the name. A middle party was formed by the conceptualists or sermonists, who maintained that universals are concepts and have ideal existence as notions in the mind, or, as Abelard more specifically held, the word becomes universal by means of predication. The formula for nominalism and conceptualism is that universals exist *post rem* (after the particular"). These discussions of the Middle Ages were powerless to advance knowledge, being mainly exercises in abstract dialectic, although carried on with great subtlety and genius in logical analysis. The question acquired, however, an important bearing by involving the doctrine of the Trinity and the existence of God. According to the realists the greater the universality, the greater the reality; the wider the concept the more extensive its being. God, as the most universal notion, has the most complete reality; as *ens generalissimum* He is *ens realissimum*. Further, the nominalists regarded as real only the individual, concrete thing. The realists urged against this that according to nominalism,

only the three persons (as individuals) of the Trinity have reality; therefore there is no Godhead and we have tritheism. Anselm maintained that the universals existed before particular things in the mind of God. The most memorable controversy on the subject took place in Paris between William of Champeaux and Abelard, in which the latter gained a dialectic victory.

Scholasticism reached its complete formulation in Thomas Aquinas who developed a system of philosophy by the fusion of Aristotelianism with Christian theology, and who sought to correlate more precisely than his predecessors the spheres of faith and reason. Reality and truth are one continuous realm, although certain truths transcend reason and are apprehended only by faith. Faith and revelation do not contradict reason; they transcend it.

An absorbing question for the late scholastics was the psychological question of whether primacy belongs to the will or to the intellect. Does the will determine our ideas, or do out ideas determine the will? Thomas Aquinas was a determinist, while John Duns Scotus represented the voluntarists. Is it the will or the intellect which is decisive in determining character? On the side of the primacy of the intellect were arranged Thomas Aquinas, the medieval Aristotelians, the German mystics, and the Dominicans; while on the side of the will were Duns Scotus, the Augustinians, William of Occam, and the Franciscans. On the question of universals, Aquinas and Duns Scotus took similar ground, namely, that of moderate realism. Both maintained that the universals exist in the mind of God (*ante rem*) as ideas before creation, substantially and immanently in things (*in re*), and as notions and names employed by the individual mind (*post rem*).

The philosophy of the Arabs during the scholastic era is essentially Aristotelianism combined with elements of neo-Platonism (the emanation theory). Their interest was mainly in medicine, natural science, and mathematics. The chief Arabic philosophers were al-Farabi (870?–950), Avicenna (980–1037), al-Ghazali (or Algazel, 1058–1111), and Averroës (1126–1198). They were important as the carriers of Aristotelianism and the seeds of natural science into Europe through Spain. The Jewish philosophy of the scholastic period is partly the cabala (a secret emanistic philosophy recorded in the works of Jezirah and Sohar) and Aristotelianism. The most important figure, however, was Maimonides (Rabbi Moses ben Maimon, 1135–1204) who combined the sublunary philosophy of Aristotle with Hebrew theology.

SCHOLIUM, skō'lĭ-ŭm, an explanatory or critical note made by an early grammarian or copyist on the margin of Greek or Latin classical manuscript. Scholia of Venetian origin on Homer's *Iliad* are among the most important to have been discovered. Most of the scholiasts have remained anonymous.

SCHOMBERG, shôm'bĕrk, **Friedrich Hermann,** 1st Duke of, German professional soldier: b. Heidelberg, 1615?; d. Battle of the Boyne, Ireland, July 12, 1690. Educated at Sedan, Paris, and Leiden, he served under Prince Frederick Henry of Orange (1633) in the Thirty Years' War, and subsequently with the Swedish Army in Germany (1634), the Dutch Army (1639–1650), the French Army (after 1650), and the Portuguese Army (1660–1668). He was naturalized in France in 1668 and became a French marshal in 1675. Forced to leave France in 1685 because of his Protestant faith, he became governor of the duchy of Prussia and commander in chief of the Brandenburg Army (1687). In 1688 he went to England with William III of Orange; there he was naturalized and created a duke in 1689, and was given command of English forces in Ireland against James II (1689–1690), winning his greatest and final victory at the Battle of the Boyne.

SCHOMBURGK, shŏm'bûrk, Sir **Robert Hermann,** British explorer: b. Freiburg, Silesia, June 5, 1804; d. Schöneberg, near Berlin, March 11, 1865. After visiting the United States (1829) and surveying the island of Anegada in the Virgin Islands (1830), he led an expedition to British Guiana for the Royal Geographical Society in 1835 and there discovered the *Victoria regia* water lily, described in his *Description of British Guiana* (1840) and *Views in the Interior of Guiana* (1841). Returning to British Guiana with his brother, Moritz Richard, in 1840–1844, he surveyed the country's boundaries with Venezuela and Brazil, establishing the so-called "Schomburgk Line." He was knighted in 1844, and became British consul in Santo Domingo (1848) and Bangkok (1857–1864).

SCHÖNBEIN, shûn'bīn, **Christian Friedrich,** German chemist: b. Metzingen, Oct. 18, 1799; d. Sauersberg, near Baden Baden, Aug. 29, 1868. He studied at Tübingen and Erlangen universities, visited England and Paris, and taught chemistry and physics at various universities before becoming a lecturer at the University of Basel in 1828 and professor after 1835. He is best known as the discoverer of ozone (1839) and as the first to produce guncotton (1845), from which he obtained collodion (1846). His works include *Das Verhalten des Eisens zum Sauerstoff* (1837), *Beiträge zur physikalischen Chemie* (1884), *Ueber die Erzeugung des Ozons* (1844), and *Ueber die Verbrennung der Körper in atmosphärischer Luft* (1845).

SCHÖNBERG, shûn'bĕrk, **Arnold,** Austrian-American composer: b. Vienna, Sept. 13, 1874; d. Brentwood, Calif., July 13, 1951. At the age of eight, Schönberg began studying the violin in Vienna, and later he taught himself the 'cello, playing with amateur groups for which he composed chamber music. He soon came to the attention of the Viennese composer and teacher, Alexander von Zemlinsky, who taught him counterpoint and engaged him to play the 'cello in the Polyhymnia Orchestra. In 1899 he composed his first important work, the tone poem, *Verklärte Nacht* (*Transfigured Night*), a sextet for strings.

After his marriage to Mathilde von Zemlinsky (who died in 1923) he moved to Berlin in 1901, where, through the influence of Richard Strauss, he obtained a position as teacher of composition at the Stern Conservatory. During this time he virtually completed *Gurre-Lieder* (*Songs of the Dove*) for which the orchestration was not finished until 1911. Returning to Vienna in 1903, he taught harmony and composition and about this time met Gustav Mahler, through whose influence several of his works were given performance. In 1911 he completed his important text, *Harmonielehre* (*Theory of Harmony*), dedicated to Mahler's memory.

Schönberg's early compositions, influenced by Wagner, Brahms, and Mahler, had been of romantic vein and traditional in form. From about 1907 his works, including the famous *Pierrot Lunaire* (1912), showed increasing elements of expressionism, such as the whole-tone scale, in a complex contrapuntal texture. By 1915 he began to experiment fully with the 12-tone system to achieve logic and unity in his music without recourse to traditional methods.

Leaving Vienna again in 1911 because of hostility toward his works, Schönberg returned to Berlin, becoming an instructor of composition at the Akademie für Kunst, and lecturer on aesthetics at the Stern Conservatory. He conducted his own works in Amsterdam (1911), St. Petersburg (1912), and London (1914), gaining international recognition, as well as evoking opposition. Following periods of military service with the Austrian Army in 1915–1917, he returned to teaching composition in Mödling, near Vienna, lectured on theory in Amsterdam (1920–1921), was married to Gertrud Kolisch in 1924, and in 1925 was appointed to a professorship at the Prussian Academy of Arts in Berlin. He held this post until his dismissal by the Nazi government in 1933 because of his Jewish descent. He then went to Paris, and from there to the United States in October 1933. After teaching at the Malkin Conservatory in Boston and at the University of California in Los Angeles, he accepted a professorship at the University of Southern California in 1936. He became a United States citizen in 1940. Although he retired in 1944, he continued to conduct classes privately. His *Style and Idea,* a collection of essays, was published in 1951.

Schönberg exerted a revolutionary influence on modern music by his abandonment of the traditional tonal system and his use of the 12-tone scale. His compositions, often discordant, raucous, and bewildering to the uninitiated, sometimes provoked audiences to storms of protest. At his death, however, few critics, whether sympathetic or hostile, would deny the significance of his contributions as composer, theorist, and teacher. Schönberg's principal works include:

CHAMBER MUSIC—*Verklärte Nacht,* sextet for strings (1899); string quartet in D minor (1907); *Kammersymphonie,* for 15 instruments (begun in 1906, performed in 1913); string quartet in F-sharp minor (1907); *Serenade* (1924); quintet for winds (1924); suite for seven instruments (1934); and two string quartets (1927 and 1936). ORCHESTRAL—*Peileas und Melisande* (1905); five pieces for orchestra: *Vorgefühl, Vergangenes, Der Wechselnde Akkord, Peripatetik,* and *Das Obligato Recitativ* (1912); *Pierrot Lunaire,* melodrama for recitation and chamber orchestra (1912); *Variations* (1928); concerto for string quartet and orchestra (1933); suite for string orchestra (1934); *Kammersymphonie,* for large orchestra (first performed in 1935, second work performed in 1940); concerto for violin and orchestra (1936); *Ode to Napoleon,* for reciting voice, piano, and string orchestra (1942); concerto for piano and orchestra (1942–1943); *Theme and Variations* (1943). OPERAS—*Erwartung,* monodrama (1909); *Die glückliche Hand,* drama with music (1913); *Von Heute auf Morgen,* one-act opera (1929). CHORAL MUSIC—*Gurre-Lieder* (1911); *A Survivor from Warsaw,* for narrator, male chorus, and orchestra (1947).

SCHONEBECK, shû'nĕ-bĕk (in full SCHÖNEBECK-BAD SALZELMEN), city, East Germany, on the Elbe River, is about ten miles south of Magdeburg and some 55 miles northwest of Leipzig on the rail line that connects those two cities. It falls within the boundaries of the state of Saxony-Anhalt. The present city limits were fixed in 1932 on the incorporation of the former commune of Frohse an der Elbe with the old towns of Schönebeck and Salzelmen. At that time the popular spa area known as Bad Salzelmen became part of the southwestern sector of the city. At the beginning of World War II, Schönebeck's industries included salt mining, metal works, and the manufacture of chemicals, explosives, and other strategic goods, all of these activities being served by an excellent harbor. Not surprisingly, the city became a major target of Allied bombers and suffered heavy damage. Pop. (1946) 44,578.

SCHONEFELD, shûn'ĕ-fĕlt, **Henry,** American musician: b. Milwaukee, Wisconsin, Oct. 4, 1857; d. Los Angeles, California, Aug. 4, 1936. He studied in Leipzig (1875–1878) and Weimar (1878–1879) before becoming engaged in teaching, composing, and conducting in Chicago and, after 1904, in Los Angeles. He was one of the first to use Indian folk melodies. His compositions include symphonies, an opera, and numerous works for strings, piano, and voice.

SCHONEMANN, shû'nĕ-män, **Anna Elisabeth,** German woman, celebrated by the poet Johann Wolfgang von Goethe under the name LILI: b. Frankfurt am Main, Germany, June 23, 1758; d. May 6, 1817. As a young man of 25, Goethe met Anna, the daughter of a wealthy banker's widow, at Frankfurt and became engaged to her early in 1775. His excellent love lyrics of that year were inspired by this girl, whose liveliness and beauty attracted him tremendously. A discordant note existed from the beginning, however, in the moody poet's discomfort when caught up in the gay, somewhat superficial social life of Frankfurt society, "Lili's" natural milieu. The engagement was broken sometime before Goethe's departure for Weimar in November of 1775. Anna later married a Strasbourg banker, Bernhard Friedrich von Türckheim.

SCHONER, shû'nĕr, **Johannes,** German mathematician and geographer; b. Karlstadt, Germany, 1477; d. Nürnberg, Jan. 16, 1547. He was a professor of mathematics at the University of Nürnberg but is best remembered as a maker of terrestrial globes. Only two of these are known, one made in 1515 and the other in 1520, but both showed a continent named America and the earlier globe may have been the first on which this name appeared. They also showed a strait at the southern end of the continent, probably a fortunate guess since Magellan's discovery occurred in the fall of 1520 and the account of his voyage could not have been reported to Schöner before 1522.

SCHONGAUER, shōn'gou-ĕr, **Martin** (also known as MARTIN SCHÖN and HIPSCH or HÜBSCH MARTIN), German engraver and painter:

b. Colmar, Alsace, 1445?; d. Breisach, 1491. The son of an Augsburg goldsmith, his earliest known works were two drawings, dated 1469. He was influenced by the Flemish painter, Roger van der Weyden, whose bright coloring and angular modeling are reflected in the few paintings which can, with any degree of certainty, he attributed to Schongauer. Among these are the renowned *Madonna of the Rosehedge* (Church of St. Martin, Colmar); *The Adoration of the Shepherds* (Berlin); and his representation of the Virgin and Child, Saint Anthony, and a donor in two wing panels of an altarpiece now at Berlin.

Schongauer is perhaps best remembered as an engraver, having been among the first to cut copper plates for reproduction. He always portrayed his religious subjects with remarkable minuteness of detail. The more than 100 engravings attributed to him include series on *The Wise and Foolish Virgins, The Passion,* and *The Death and Coronation of the Virgin.* Specific engravings such as *The Adoration of the Magi, The Death of the Virgin,* and the diabolical *Temptation of Saint Anthony* are considered masterpieces. He was famous in Germany and Italy during his lifetime and founded, at Colmar, a school of engraving which produced many gifted artists of the late Gothic period.

SCHONHAUSEN, shûn-hou'zĕn (also SCHÖNHAUSEN AN DER ELBE), village, East Germany, near the Elbe River, about 35 miles north of Magdeburg. It was formerly in the Prussian province of Saxony and is now in the *land* (state) of Saxony-Anhalt. It is renowned chiefly as the family seat and birthplace of Prince Otto von Bismarck. A village of considerable antiquity, it can boast a 13th century church. Pop. (1946) 3,281.

SCHONHERR, shûn'hĕr, **Karl,** Austrian dramatist: b. Axams, Tirol, Feb. 24, 1869; d. Vienna, March 16, 1942. A physician as well as a playwright, his plays are frequently concerned with medical and peasant people of the Tirol. At the age of 26 he turned from writing poetry and short stories in Tirolese dialect to the theater, his plays subsequently winning the Schiller Prize in 1908 and the Grillparzer Prize in 1911, 1917, and 1920. His works include *Die Bildschnitzer* (1895); *Judas von Tirol* (1897, revised in 1927); *Erde* (1907); *Glaube und Heimat* (1910, Eng. tr., *Faith and Home,* 1913–1915); *Der Weibsteufel* (1915); *Volk in Not* (1916); *Es* (1923); *Die Hungerblockade* (1925); *Der Armendoktor* (1927); *Herr Doktor, haben Sie zu essen* (1930).

SCHONINGEN, shû'nĭng-ĕn, town, Germany. About 30 miles west of Magdeburg in northwest Germany, it was formerly part of Brunswick and is now in Lower Saxony. It has salt, rubber, and machine works, a 14th century castle, and a Romanesque-Gothic church. There was already a settlement here in 747 A.D. Pop. (1950) 15,583.

SCHOOL DISTRICT. See DISTRICT.

SCHOOL FOR SCANDAL, The, by Richand Brinsley Sheridan (q.v.), was produced May 8, 1777, by the author himself as manager and part owner of Drury Lane Theatre, which he had taken over some time before from David Garrick. Unlike the earlier *The Rivals* the play was an instant success. It ran 20 nights the first season, 65 nights the second season, and has held the stage ever since.

The School for Scandal, the only play of later date to challenge comparison with William Congreve, may be studied as an index of dramatic tendencies since the Restoration. The movement for correcting the morals of the stage, traces of which were seen in *The Way of the World,* have now culminated in a definite brand of technique. Though scandal is spoken in the play none is actually seen in the action. The polite subterfuges demanded by modern English taste have begun. The tradesman has been introduced into comedy. Moreover, though Sheridan ridicules sentiment, the primary action of the play revolves around a sentimental motive. Joseph Surface is a false sentimental hero, while Charles Surface is a true sentimental hero. Oliver and Rowley are characters from sentimental comedy.

The School for Scandal is of the school of Congreve once removed. Whereas Congreve conventionalizes life, Sheridan conventionalizes the stage. With Congreve, wit is the specific; with Sheridan it is entertainment. *The School for Scandal* is a crowded fabric of "situations" derived from a broad reading of English comedy and an intimate acquaintance with the stage. Much worked over in composition out of scattered scenes and different plays, the central idea of a school for scandal goes back to the cabal nights of Lady Wishfort in *The Way of the World.* Action has become more important than speech, and events follow each other in rapid succession. There is little repartee. The brilliancy of give and take gives way to broken monologues. Dialogue serves not as a fencing of wits but as the rapid patter of characters, manipulated through a foreordained intrigue. To keep the conversation running rapidly is the first requirement. Therefore a spirit of raillery is maintained.

When these things are said it must be admitted on the other side that the play occupies a significant position. It was the last of the comedies of manners and the first of the modern plays of entertainment. The former were written for the discriminating; the latter for the crowd. The plot is regular and expert in the handling of a crowded action. In theatrical "effects" the play has been a storehouse of devices for a century of writers of comedy. On account of its adjustment of old materials to the requirements of the new day the play has maintained vitality unabated to this day.

SCHOOL SUPERINTENDENT, The. The office of superintendent of schools is a unique American institution, evolving from a need to meet certain demands. The United States was the first nation to attempt provision of universal public education. The size and scope of the task dictated forms and kinds of organization and administration which were not needed to the same degree by other nations. These demands upon organization and administration finally led to the establishment of the office of the superintendent of schools.

Growing Schools and Communities.—America in the 17th and the early part of the 18th century was sparse in population and almost entirely lacking in transportation and communication facilities. For the most part people lived in isolated communities and there were no large cities. Schools, therefore, were small, housed mostly in

one- and two-room buildings. The program of the school was simple, the teaching of the rudiments of learning being the main task. Then, with the rise of the immigration rate, the beginnings of the Industrial Revolution, and the resulting complexities of the economy, the trend developed for people to live together in more closely knit communities. Individual schools became larger and the demands made upon them were more diverse.

The Superintendent of Schools Emerges.—By 1850 many schools had 10 or more classrooms in a building. An increasing number of communities found it necessary to have several buildings in order to house the growing school population. These conditions led to the need for someone to help the heretofore self-sufficient teacher, and also to perform tasks which applied to the entire school rather than to the individual classroom. School boards, as a result, began to add to the school staff a person who was assigned these tasks. Sometimes called a head teacher, later a building principal, this position finally evolved into the office of superintendent of schools. Buffalo, N. Y., and Louisville, Ky., in 1837 were the first two cities to establish this office.

Schools and Governmental Structure.—To understand the office of school superintendent, one has to understand the framework of governmental structure in the United States which is based upon the concept of three levels of government. All are interrelated and at the same time are largely separate from one another; all have a concern for education. At the federal level, the top official is the commissioner of education. He is appointed by the president and has few executive functions. The duties of his office are, primarily, those of leadership, service, and research. In turn, each state has a superintendent of schools (sometimes called state commissioner of education). As education has been held to be a state function, this officer, in most states, has many important responsibilities for the maintenance and operation of schools. The first state to create this office was New York in 1812.

The superintendent's position at the state level evolved from the function of statistics-gathering and reporting to the leading educational place in a state. By legislative enactments, he is charged with general supervisory control of all public schools in the state. In addition, many specific responsibilities are placed upon him: for example (1) certification of teachers; (2) recommendation of needed school legislation; (3) approval of plans for new school buildings. In the first half of the 20th century, emphasis was given to the regulatory or law enforcement aspects of the office. Since World War II, increasing emphasis has been laid upon leadership and research.

Within the state there are two types of school units, county and local district. The county as a unit of school organization is commonly found throughout the United States. Ordinarily, it is an intermediate unit between the state and the local community. Most counties have an officer called county superintendent of schools. In a majority of these counties, this official does not actually manage or operate schools directly. However, in 12 states (mostly in the South) the county is the only local unit for the operation of schools.

The main type of school unit is the local or community school district. The chief administrator of these districts is called the superintendent of schools. (In a few states, the title used is supervising principal. In a few instances, the term superintendent of education is used.)

Requirements for the Office.—The state superintendent of schools attains his office in various ways. In the majority of the states, he is elected by the people of the state. In several states, he is appointed by the governor. In still others, he receives his appointment from the state board of education. The last method is receiving increasing favor; it is the method of selection advocated by students of school administration.

County superintendents of schools are most frequently selected by popular vote. The method recommended is selection by a county board of education, a method increasingly used. Various other methods of selection are found infrequently.

Local superintendents of schools are almost universally selected by local boards of education.

The salaries of superintendents are generally fixed by the appointing school board. However, at the state level the salary is frequently set by legislative enactment. The term of office ranges from fixed terms, usually one to five years, to indefinite tenure at the pleasure of the appointing board. In most cases, superintendents are not eligible for legal tenure.

Requirements for appointment range from almost none to advanced university graduate work and successful experience. The most frequent requirements are graduation from college, experience as a teacher, and completion of certain specified college courses. That a superintendent must hold a state certificate, usually of the highest grade, has become an almost universal requirement. In some states, special superintendents' certificates are required.

The school superintendency has grown rapidly in America from its humble beginnings in the second quarter of the 19th century. The office is now found universally in every state, every county, and in the vast majority of local school districts (practically all having six or more teachers). It has attained status and is accepted as an essential part of a school system. The evolution of the scope of the office is even more noteworthy than its quantitative growth.

Evolving Duties of the Superintendent.—The superintendency began in simple fashion. Most of the tasks were clerical and designed to relieve teachers from a growing burden. Another task was disciplinary in nature: the unruly had to be made to obey. Someone had to meet the parents and discuss school problems with them. Thus, the office was created and began to operate. As the job progressed, additional tasks were added, among them being the care of the building, selection and purchase of supplies, and advice to teachers who needed it.

The real development of the superintendency, however, began in the first quarter of the 20th century. It was in this period that colleges and universities began to offer specific preparation for the office of school superintendent. Students increasingly were attracted to the position, and hence undertook the preparation offered. School boards began to consider preparation for the office in their selection practices. Thus began the professionalization of the position and its acceptance in the list of essential jobs in a school system.

With the beginnings of preparation for the office, reconsideration was given to the value of the position and the tasks which should be performed. Studies were made to determine what

superintendents actually accomplished, and thought was given to what they should do. The results have had an important bearing on the preparation programs for the position. Since the early 1900's there have been various emphases which have closely paralleled similar ones for industrial management. Among them are: the superintendent's role as a technician (for example, preparation for financial accounting); his role as a manager (preparation for organizing and operating school bus transportation); and his role of community and school leadership (understanding of group dynamics).

Transition to Democratic Practices.—The role of leadership has received major attention since World War II. In the early era of school administration, the superintendent of schools tended to operate by fiat. He was an authoritarian, and his decisions were made with little participation of others. Undoubtedly the methods of Prussian schoolmasters influenced this practice. Since World War II it has been increasingly recognized that a leadership role in a free society should be in harmony with the concepts of the meaning of a free society. Equality and the right of participation of all concerned in a given enterprise led to a sharing in policy making and planning. The trend affected the work of school superintendents—their preparation and their methods.

It was not easy, however, to make the transition from authoritarian to democratic practice. Prodigious efforts were required. The American Association of School Administrators brought its influence and efforts into action. Professors of school administration founded the National Conference of Professors of Educational Administration and accepted as a major activity the translation of the preparation of school administrators primarily into a democratic leadership conception. The work of these groups and others led the W. K. Kellogg Foundation to provide a grant which totaled almost $5 million to assist in improving school administration. Starting with a five-year program, superintendents and faculty personnel of universities attacked the problem. Results show definite progress toward more democracy in administration and toward the assumption of a greater role for superintendents as community leaders. The role has shifted from *things* to *people*. At the same time, the higher education institutions preparing superintendents have shifted their emphasis from the superintendent as a manager and a technician to the superintendent as a person who must know how to get along with people. The stress is on leadership and how it works.

Functions of a Superintendent of Schools.—The functions of a superintendent of schools are many and diverse. The superintendent of schools has a dual relationship to the local school board. First, he is the professional adviser to the board, counseling it on policies it should consider and adopt. Secondly, he is the executive officer of the board and as such is given the responsibility for carrying out the policies which the board enacts.

To the teachers and employees of the school district, the superintendent of schools is a professional leader. He helps to determine the educational program, recommends competent personnel, and aids in the in-service preparation of the staff.

To the people of the school district, the superintendent is the interpreter of education. He helps citizens to understand educational problems and issues, and he provides information about all phases of the work of the schools.

The superintendent is also responsible for the business management of the schools. He not only prepares and recommends the annual school budget, but also administers it. He guides the school board and the community on school building issues, and administers the maintenance and operation of the plant. He recommends the purchase of materials and supplies, and when decisions have been made, purchases the materials and is responsible for their use.

Office of Superintendent in Other Countries.—While the office of superintendent of schools in America is unique largely because of the ideology of a particular kind of free society, similar offices are found in the educational systems of other lands. In authoritarian countries such as the Soviet Union, this officer dictates what is done. He represents the state and the state is supreme. In the democratic countries the picture is more complex. Since the free countries are striving to use education as a means of developing individuals in a free society, in the majority of them education has a place at the highest governmental level. A minister of education has equal status with the minister for foreign affairs, war, or finance. This official, then, is administratively responsible for schools and ordinarily he has broad administrative powers. As a result, in those countries there is a centralization of power at the top. Orders are issued to the local level, and consequently superintendents or their counterparts are concerned chiefly with carrying out orders and operating schools.

Great Britain, however, since passage of the Education Act of 1944, has moved to place greater authority for schools at the local level. In Canada the school official in the provincial government exercises the greatest power. Since 1945, many countries throughout the world have sought American missions on education and consultants on their educational problems. There are indications that, as a result of such work, there is a growing trend toward more local control of schools and some emphasis on a greater degree of democratic administration.

WALTER D. COCKING,
Editor, "The School Executive."

SCHOOLCRAFT, skōōl'kråft, **Henry Rowe,** American ethnologist and author: b. Watervliet, Albany County, N. Y., March 28, 1793; d. Washington, D.C., Dec. 10, 1864. He was educated at Middlebury and Union colleges, in 1820 was made geologist to an exploring expedition under Gen. Lewis Cass to the Lake Superior copper region and the upper Mississippi, and in 1822 became Indian agent for the northwestern frontier, with headquarters at first at Sault Sainte Marie and later at Michilimackinac (or Mackinac). From 1828 to 1832 he was a member of the Michigan territorial legislature. He commanded in 1832 the expedition which discovered the sources of the Mississippi, and in 1836 concluded with the Indians about the lakes a treaty by which cession of 16,000,000 acres of land was made to the United States. Soon afterward he received the appointment of acting superintendent of Indian affairs and disbursing agent for the northern department. In 1847 he began the preparation, under government ap-

pointment, of his elaborate work, *History and Statistical Information Respecting the History, Condition and Prospects of the Indian Tribes of the United States* (1851–1857). For the first five volumes an appropriation of nearly $30,000 per volume was made by Congress; the sixth and last was published at the expense of the War Department. The work was finely printed, and illustrated by 336 plates. It was the first means of introducing Indian legend and tradition to the general reader and gained a considerable reputation as a work of scholarship. Among Schoolcraft's other volumes are *Algic Researches* (1839); *Oneota; or Characteristics of the Red Race of America* (1844); *Personal Memoirs of a Residence of 30 Years with the Indian Tribes* (1851); and *Scenes and Adventures in the Semi-Alpine Regions of the Ozark Mountains* (1853).

SCHOOLEYS MOUNTAIN, skōō'lēz, village, New Jersey, in Morris County, on Schooleys (or Schooley) Mountain 17 miles west of Morristown. The mountain, for which the village is named, is about 1,000 feet high and is a flat topped ridge of the Appalachians. Pop. (1950) 250.

SCHOOLS, Supervision of. The supervisor in educational systems today is an expert consultant who, by applying democratic methods and procedures, attempts to secure improvement in the teaching and learning environment, and to facilitate the attainment of educational objectives. Even supervision as applied to personnel is reflecting the greater knowledge of basic principles of human relations, and the ability to apply them.

In many of the countries of the world, however, the process of inspection still prevails. Officials critically investigate schools to determine whether ministerial rules and regulations are being observed and educational laws enforced. In other countries, while the terms "inspection" and "inspector" are used, the trend, as may be observed in Canada and England, is in the direction of voluntary consultation on an observation, advisement, and assistance basis. The concept of inspection in the United States is limited to such matters as regulations governing receipt of state aid, school building construction, fire and health hazards, school lunch programs, length of school year, certification of educational personnel, and so on. The term "inspection" no longer is used with reference to the instructional program.

Inspection Under Totalitarianism.—The function of government in educational control under Germany's Nazi regime (1933–1945) was perfectly clear: it was the subordination of the individual to the state. The state merely became a convenient vehicle for the indoctrination of the individual in the ideology of the party. Under the Nazi regime inspection was rigid and included every phase of life. It extended from the Reich ministry to every school and educational medium in the country. Even the faculties of universities were subjected to inspection.

Thus, the content of textbooks was basically a presentation of party ideology. Youth organizations uniformly were subjected to party indoctrination. In fact, the system of inspection was so complete and rigid that education officers in the *Länder*, or states, and the subdivisions thereof merely carried out orders from above. This is the totalitarian formula wherever such a system exists.

The English System.—Prior to the adoption of the Education Act in 1944, the responsibility for education in England was in the hands of the board of education and the president of the board was the political head of the educational service. In 1944 the Rt. Hon. Richard A. Butler, the first minister of education, successfully piloted through Parliament the Education Act, which was to expand and improve the educational service. The minister has the authority to appoint a parliamentary secretary and their responsibilities, in addition to the administration of the Ministry of Education, comprise answering whatever questions may be addressed to them by members of Parliament, either on the floor of the House of Commons or otherwise. They also present legislation or regulations for action.

There is a staff of about 3,000, comprising three different types of personnel: (1) The administrative personnel is largely recruited from the civil service and represents men and women of high distinction who have chosen civil service as a career. (2) Her Majesty's inspectors are men and women who have been in the educational system or with the educational service. They represent personnel of high academic distinction who have entered the educational field in the service of local education authorities, universities, or independent schools. They are selected on the basis of merit for appointment to the inspectorial staff of the ministry. (3) Finally, there is the group known as nonprofessional personnel.

The most important principle on which the English system is based is the distribution of power. Inspection of schools is provided by the local as well as the central authority. William P. Alexander points out in his book *Education in England* (1953) that ". . . The best safeguard for democracy is to insure that a madman coming to power cannot ruin the people. It will be readily conceded that when Hitler came to power in Germany, the fact that he could determine what was taught in the schools of Germany was perhaps the most important factor in creating and consolidating the Nazi Regime."

Thus, while inspection is provided by the ministry, the distribution-of-power principle is the safeguard against autocratic control of the educational system by the central authority. Therefore, at the ministry level, the senior chief inspector heads the service. There are chief inspectors for different types of schools. Divisional inspectors are concerned with particular regions of the country. Staff inspectors and Her Majesty's inspectors of schools are concerned with a limited area, in many cases one local education authority. It is the responsibility of the inspectorate to satisfy the minister that schools are properly conducted in accordance with the statutory and regulative requirements. Her Majesty's inspectors are consultants and advisers available to teachers and local education authorities. They are ready

and willing to give advice, if such is sought. There is no requirement that such be accepted.

Provincial System in Canada.—Since the time of Confederation in Canada (1867), education has been a responsibility of the constituent provinces. As in the United States, where education is recognized as a state function, in Canada it is a provincial function. Within the 10 provinces are approximately 700 inspectors or superintendents of schools, their principal responsibility being supervision. About 10 per cent of the inspectors or superintendents are appointed by local boards of education in cities or large school systems. Ordinarily, however, provincial approval must be obtained for the appointment of these officers. Ninety per cent of the inspectors and superintendents are appointed by the provincial department of education and are employees of the department. Likewise the province and the officials therein determine what constitutes an acceptable minimum educational program. However, certain functions, as for example providing and operating the school plant and program, are delegated to the local education authority.

A generation ago much of the work of the inspector, as was the case in the United States, consisted of a visitation to each school in his area. He would satisfy himself that the school was in session, examine the school register, inspect buildings and grounds, and perhaps confer with the chairman or secretary of the school board. One of the basic responsibilities, however, was to see that the prescribed courses of study were followed and that school laws and regulations were observed. Inspection in this limited sense remains a part of the inspector's duties. However, improving the quality of education and ascertaining whether or not objectives are being met are the primary responsibility of supervision.

Supervision also is carried on through specialized personnel and through the office of the school principal. A knowledge of, and ability to apply, basic principles of human relationships and democratic leadership characterize the supervisory trend in Canada. Supervisors work with educational personnel. There is a mutual educational atmosphere in which teacher learns from supervisor and supervisor from teacher, and group procedures are becoming more and more evident in school supervision.

There are certain trends in supervision in the provinces. Among these are the following: (1) shifting emphasis from the teacher to the teaching-learning process and to the pupil; (2) leadership in developing better communication between schools and the public; and (3) the development of special provincial legislation, allocating authority and responsibility to local authorities to determine educational policy in the larger and wealthier cities. The increasing complexity of administrative problems has complicated the role of supervision. More and more the school principal is becoming an important part of the supervisory program, as well as the program of in-service teacher education. In Canada, then, the trend is toward cooperative effort and away from autocratic direction.

SUPERVISION IN THE UNITED STATES

The heart of an educational system is the educational program. Educational supervision in the United States increasingly has become a matter of contributing to the advancement of education through improvement of instruction and the teaching art by means of consultation and cooperation.

As previously indicated, in many states and local communities the term "supervisor" has been abandoned in favor of the title "consultant" or "curriculum coordinator." The matter of supervision as used in this connection, therefore, is a most important responsibility in every school system. Evaluation to ascertain whether or not educational objectives are being met is important. Understanding human development and the fundamental principles of human relations are basic in school supervisory programs. Helping the individual to become a more effective teacher and providing expertness in curriculum development are responsibilities of what we now call supervision.

While the state may provide general and specialized consulting service, the major responsibility for supervision is delegated to the local school system. The special supervisor in such fields as reading, art, and music will be found in the larger cities and in many larger administrative units. The general supervisor, as, for example, the supervisor of elementary or secondary education, may be part of the supervisory staff; or this responsibility, in many cases, becomes the role of the superintendent or school principal.

Federal Supervision.—A portion of the supervisory program, in small measure, is inspectional in nature. At the federal level, for example, there is little inspectional responsibility with respect to education. In vocational agriculture and other vocational areas for which federal funds are allocated to the state, state plans for these respective spheres must be approved by the United States Office of Education. Accounts are audited to see whether or not the funds are being spent for the purposes for which they were allocated. There may be occasional visits by regional and national representation to see whether or not the plan as presented is actually being carried out. In the case of the school lunch program, again the function of audit and inspection to ascertain whether or not the funds are being spent for the purposes indicated in the act, would be a responsibility of federal representatives, though each state involved in this program also would have a similar responsibility. This same inspectorial responsibility would be found at the national level in programs of rehabilitation, veterans educational programs, contractual relations between universities in this country and universities where these relationships involve federal funds either under technical assistance plans, or the Department of State, or such agency as would be concerned with foreign aid.

State Functions.—The inspectional responsibilities of the state are carried out largely through the state department of education. There are certain regulative responsibilities set forth in the statutes generally involving the establishment of standards with which the local community must comply. Among these inspectional functions are the following:

(1) The certification of teachers. Though the certification requirements for educational personnel generally represent minimum standards for admission to the profession, the local community is permitted and encouraged to go beyond these standards in the employment of the educational personnel. Much of the control element involved in certification could be removed if the various educational organizations for teachers and teacher

training institutions could agree nationally on a body of standards for admission to the profession. Standards vary from state to state. However, because of the critical shortage of teachers at this particular time (1956), there is a tendency to issue a temporary certificate until standards are met. There is also a trend toward reciprocity among the states, especially in New England and in the Middle Atlantic region.

(2) Building codes. In most of the states, a building code has been developed by the department of education, usually with the collaboration of organizations in that state. When a board of education desires to construct a new school building, it is necessary to meet the standards contained in the state code which usually include standards regarding the school site. These codes have gone beyond the safety factor alone and include other matters, such as the size of the classroom, width of corridors, and standards for special facilities, for example, shops, laboratories, and other facilities.

(3) Approval of degree-granting institutions. In many states the state board of education is charged with the responsibility of inspecting and evaluating institutions which seek the degree-granting privilege. The procedure varies from a department expert who reviews the petition, to state departments that bring in outside evaluators to study specific programs in the institution.

Such matters as (4) transportation, (5) the age at which a permit to work may be issued to a child, (6) the specification of the compulsory attendance period, and (7) the number of days schools must be in session—all require inspection on the part of the state though inspection in several instances may be delegated to the local community.

With respect to the educational program, there is an element of inspection still remaining in those areas which are mandated by state legislation; in other words, the state has the obligation to see that certain courses (such as conservation, the effects of alcohol and narcotics, citizenship training, and United States history) are included in the educational program by the local board of education. The government is also responsible for protecting such areas of life as health, natural resources, individual rights, and national security.

If legislation is enacted, the provision of the law should be stated in general terms, leaving to the individual school district the authority for developing the course of study and for deciding on the kind of training which will produce individual competence to live in this complex modern society. The trend toward the inclusion of specific mandates in the law with respect to what shall be taught in the educational system presents certain dangers. It could lead to control of the content of education by the state; also, statutory requirements might become so complex that little but these specifics might be offered by the board of education.

Local Supervision.—Supervision at the local level is the responsibility of the local board of education which provides personnel to carry out state-mandated responsibility. In earlier times the responsibility for ascertaining why students were not in the classroom, or who were absent for unusual periods, was vested in the truant officer. Later on school boards appointed attendance officers. The trend during recent years has been to place the responsibility in the hands of the school social worker. Inspection of school buildings for fire and accident hazards usually is a responsibility of the chief state fire marshal, but ordinarily such duty is carried out locally by the fire authority in the local community.

In many cases, inspectors from the state motor vehicle department provide for the inspection of school buses in areas having large transportation programs. The maintenance of standards of sanitation in cafeterias may be the responsibility of the local health authority; in instances where the board of education has its own health department, inspection may stem from there.

University Programs.—Many state universities employ a high school visitor. His function is to ascertain which schools shall be placed on the accredited list for purposes of admission to the university. Private universities and colleges also have such relationships with the secondary schools. Likewise, inspectional programs are maintained by sectarian organizations for those schools and institutions of higher education that come under their jurisdiction.

Nongovernmental Inspection Agencies.—Quite apart from governmental inspection programs, there are many organizations and agencies which inspect institutions that wish to be recorded among approved institutions and certified as having met the standards of the particular accrediting agency. One of the more difficult problems in the United States has been the multiplicity of accrediting agencies. Different agencies inspect and accredit schools of medicine, engineering, pharmacy, law, social work, and the like. In addition to the American Psychological Association, which approves courses in clinical psychology, there are other such agencies. More recently a movement has developed to consolidate some of these efforts and to secure greater coordination in the present segmented manner of accreditation of institutions.

In some states, as previously indicated, the state board of education or state department of education is legally authorized to inspect institutions for purposes of accreditation, and in many states a charter for the establishment of an institution cannot be granted without the approval of the state board of education and its recommendation to the legislature. Institutions may be inspected by the American Association of University Women to determine whether or not the standards and program of the institution qualify the graduates for membership in this organization.

While these national and regional accrediting agencies ordinarily have no legal authority to accredit an institution, a school which is not on the accredited list is at a disadvantage in that it does not enjoy the prestige of approval; should a graduate desire to continue his studies at a professional school, he is not likely to be accepted in institutions on the approved list.

ALONZO G. GRACE,
Associate Dean, School of Education, New York University.

SCHOOLS OF DRAMA, Modern. Drama is in a constant state of flux. Nothing begins and ends precisely. No other literary form is so sensitive to changing public tastes as the theater, and for that reason there are always new groups of playwrights forming, and older groups dissolving and blending into the new. A school is the name given to a group of playwrights who, through principles and procedures, fit loosely into

a pattern that can be distinguished from other patterns. Critics and historians have labeled these groupings for the sake of clarity and understanding.

Because Henrik Ibsen represented a distinct break with the past, and has influenced in some way almost every 20th century playwright, the works of Ibsen are considered as the beginning of modern drama. Ibsen was the leader of the school of realism. He explored realistically and honestly many of the controversial aspects of life in the last two decades of the 19th century. He wrote, to his way of thinking, without compromise with his audience or with the critics of the day. Among his important plays are *Peer Gynt, A Doll's House, Ghosts, An Enemy of the People, A Wild Duck, Hedda Gabler,* and *John Gabriel Borkman.*

Since no school rises independently of what has gone before, it is important to review some of the great theater movements which preceded Ibsen. The first great school of drama was the Greek which flourished during the 4th and 5th century B.C. The plays were highly stylized, followed semireligious forms, and limited themselves to traditional themes and situations. Among its remembered playwrights are Aeschylus, Sophocles, and Euripides in tragedy, and Aristophanes in comedy. The Roman school emerged in the middle of the 3d century B.C. and lasted until the middle of the 1st century A.D. Plautus and Terence (2d century B.C.) were the outstanding writers of comedy; Seneca (1st century A.D.) was the most important writer of tragedies.

Medieval schools of writing developed the mystery, the miracle, and the morality plays which grew out of the liturgy of the church itself. Beginning with the 9th century, these schools gradually blended with the literary and professional elements of the theater until, by the middle of the 16th century, the medieval qualities were absorbed by the Elizabethan dramatists.

The Commedia dell' arte (improvised comedy) was a significant force in the theater from the early 16th century to the middle of the 18th. Originating in Italy, it spread throughout Europe and England. The comedies possessed only a skeleton outline to be filled in by the originality and inventiveness of the actors. Neo-Classicism (Classic French school) has as its leading exponents Pierre Corneille, Jean Racine and Molière (Jean-Baptiste Poquelin). Playwrights of this school reached their heights during the last two thirds of the 17th century. They carried the Greek unities of time, place, and action to the extreme, and wrote for an intellectual and limited audience.

The Elizabethan school, which marked the late 16th and early 17th century in England, was perhaps the greatest creative period in the history of literature. The play itself was the great intellectual stimulus, and the works of Shakespeare overwhelmed all other works. While Elizabethan plays followed classical models, they exhibited flexibility of form and showed concern for human problems and conflicts.

The school of Restoration playwrights (1660–1710) was marked by wit, superficiality, and sophistication, John Dryden, Sir George Etherege, William Wycherley, Sir John Vanbrugh, William Congreve and George Farquhar were representative playwrights.

There were several schools of romantic playwrights. Spain experienced a dramatic revival contemporary with the Elizabethan drama, in which plays were molded to a romantic pattern in plot, dialogue, and action. Pedro Calderon de la Barca, Lope de Vega Carpio, and Miguel de Cervantes Saavedra were the notable playwrights. The first three quarters of the 19th century saw another romantic school arise in France. Victor Hugo was the most successful figure in that group.

In the last half of the 18th century, a Classic school arose in Germany, attracting such major literary figures as Gotthold Ephraim Lessing, Friedrich von Schiller, and Johann Wolfgang von Goethe. Eugène Scribe and Victorien Sardou were exponents of the well-made play in which ingenuity of craftsmanship was more important than characterization and meaning. This late 19th century movement had among its exponents in England Arthur Wing Pinero.

In the last quarter of the 19th century, throughout Europe and America, came an exciting, almost spontaneous awakening. The playwright seemed suddenly to realize his potentialities. In the face of public and critical disapproval, he refused to be bound by traditional dramatic conventions and dared to explore society and human nature. His new-found power gradually inspired a similar awakening throughout the theater world.

The naturalistic school of playwrights developed almost concurrently with the realistic. The naturalistic playwright defied the conventionality of the formalized theater and sought to express life as it was without comment and without compromise. Abnormality, crime, disease, economic exploitation of the working classes, and insanity, were among the subjects which preoccupied the playwrights. While there were naturalistic elements in August Strindberg (Sweden), Anton Chekhov, Maxim Gorky, Count Leo Tolstoi (Russia), Eugène Brieux (France), Hermann Sudermann and Gerhart Hauptmann (Germany) were the acknowledged leaders of this movement. It must be remembered that no modern school of playwriting dies out completely nor does it ever dominate. There is a cumulative effect with the immediate past always being felt, yet there is the constant pressure of the new and the changing. A modern school of playwriting will owe something to every trend since the realism of Ibsen. The pure naturalist may no longer exist, but the early exponents of naturalism opened the way for many more modern playwrights.

Symbolism was a reaction against realism and naturalism. The symbolists (playwrights, painters, and poets) elevated the concept of inner truth expressed by suggestion to much greater significance than the outward, physical action. Maurice Maeterlinck was the great leader of this movement.

Impressionism was a revolt against the realism of appearance. Through simplicity and selection of detail, larger implication was achieved. Impressionism was carried farther by the expressionists. The expressionists, through selection and impression, wrote what they felt to be basic truths of life. This expression, they felt, was desirable even though the audience did not follow it, and even if the results were brutal, shocking, abrupt, and extravagant. Frank Wedekind, Ernst Toller, Franz Werfel and Georg Kaiser were the chief exponents of expressionism in Europe. Elmer Rice's *The Adding Machine,* George Kaufman and Marc Connelly's *Beggar on Horseback,*

Eugene O'Neill's *Emperor Jones* are impressionistic-expressionistic. In differentiating impressionism and expressionism it is probably well to note that impressionism is concerned with the feeling of truth produced by the production of the play. It deals with sets, costumes, and properties that give the right tone or feeling—and in doing so affects the structure and the dialogue for the play. Expressionism is concerned with an inner feeling of truth within the play that may be produced by symbols, fantasies, and dialogue that have little resemblance to the actual world.

In Paris, boulevardism was a school whose best known exponents were Charles Maurice Donnay, Felix Henri Bataille, Paul Hervieu. It was preoccupied with the sex relationship of men and women without much regard for reality, but with considerable attention to the whims of the audiences that patronized the boulevard theaters. The Gallic attitude toward love often shocked or at least confused English and American audiences. Boulevardism flourished from the turn of the century to World War I, although elements of boulevardism continue in the French theater.

English drawing room comedy has had followers consistently from the middle of the 18th century to the present time. The intention is to be gay and witty; the production is easily staged; the opportunity for the actor is great; gowns and dinner jackets, tea and cocktails, estates and servants are essential. The plays are often popular for years in the college and community theater. Their charm, when sympathetically acted, is pervasive. While these plays are usually written with both eyes on the box office, they often have a literary value in the quality of the writing that lifts them above the average of general theater standards. Richard Brinsley Sheridan, Oscar Wilde, W. Somerset Maugham, Noel Coward, Alan A. Milne, Ivor Novello in England, and Philip Barry, John Van Druten and Samuel N. Behrman in America are among the best of the writers of drawing room comedy.

The playwrights interested in social dramas have been numerous, insistent, and talented. They are aggressively concerned with the exploitation of the weak, impoverished, or economically unfortunate; they often put the responsibility for social injustice on a capitalistic society; they deal with strikes, scenes of struggles and violence; they are concerned with the unjust treament of racial minorities. This school, a direct descendant of Ibsen, is sometimes called the School of Social Protest or Proletarian drama. George Bernard Shaw, John Galsworthy, Sean O'Casey, Clifford Odets, John Howard Lawson, Sidney Kingsley, Irwin Shaw, Marc Blitzstein, and Lillian Hellman are among those writing plays that have explored social issues.

Folk, regional, and rural drama are all somewhat in the same grouping since they rely strongly on the influence of environment on the lives and actions of the characters. Rural drama in the 19th and early 20th century portrayed, usually with comic emphasis, the problems of country types often in conflict with the unprincipled exploiter from the city, with the rural characters possessing an unusual shrewdness that made them the ultimate victors. The rural drama gave us such types as the Yankee in the 19th century and the vaudeville rubes in the 20th. As rural drama gained realism and authenticity, it was called folk drama. It dealt with simple, illiterate, remote people with increasing insight, poetry, and understanding. Folk drama had its roots in the 19th century but playwrights like Percy Mackaye, Paul Green, Lynn Riggs, and Marc Connelly gave it beauty, interpretation, and a secure position in the American theater. Regionalism is the larger term that encompasses folk and rural drama because regionalism is the school of drama in which the region, area, and environment, is the dominant force in the creation, interpretation, and production of the play. Regionalism had its expression in England with the Birmingham Repertory Company, in Ireland with the Abbey Theatre and the Irish Players, in the United States with the Carolina Playmakers. Regionalism is now a part of the contemporary theater tradition, though until the 1930's, it was thought of as the particular preoccupation of the "little" and experimental theaters.

Surrealism is that school of writing which presents the subconscious with no necessity for form or meaning other than the dreamlike association of ideas. The playwright may or may not have a meaning grasped by the audience, but if he creates an emotion, that is enough. Surrealism is more likely to be an element in the theater rather than the entire play. It lends itself most easily to the one-act form.

The psychological play appears in various forms. Elmer Rice's *Dream Girl* and Moss Hart's *Lady in the Dark* explore the problems of psychoanalysis. The psychological horror play, exemplified by *Laura, Rebecca, Night Must Fall, Blind Alley, The Two Mrs. Carrolls,* shocks the audience. Its purpose is to present in a plausible, well-motivated manner a terrifying situation. It usually involves murder based on a psychological aberration.

Two schools of farce have appeared in America with such definite characteristics that one is noted as the play with the George Abbott touch; the other the play with the George Kaufman touch. The Abbott farce is fast paced, wisecracking, with rapid-fire gags and dialogue. It is superficial in characterization but never lacking in humor. The humor is observant and ingenious rather than satiric and penetrating. Each play seems indelibly stamped with the personality of George Abbott. Some of the plays which carry the imprint of his technique are *Room Service, Brother Rat, Three Men on a Horse, What a Life,* and *Kiss and Tell.*

George Kaufman has had many collaborators yet all of his plays have a style that is defined as the Kaufman touch. His farces are sharp, cruel, penetrating, freely associative. They are satiric and show psychological insight into human affairs. *Dulcy, Once in a Lifetime, Of Thee I Sing, June Moon, Beggar on Horseback, The Man Who Came to Dinner* are popular examples of this school.

The Federal Theater set up by the United States government during the depression of the 1930's as a relief measure for professional theater people, prompted some of the very important experimental activities of the 20th century. Several of the Federal Theater units, particularly those in New York, Chicago, San Francisco and Los Angeles, had hundreds of trained performers on their rolls. This abundance of personnel made it possible for the Federal Theater to stage spectacles involving myriads of performers. The writers would take a problem like housing in New York and explain, by the use of motion pictures, slides, music, dance, speeches, episodes

of a realistic, or expressionistic, or surrealistic nature, the significant implications of the modern housing problems. The projection of a problem was the first necessity. Any device known to the theater could be used to interpret a social or an economic problem in a realistic, informative way. This provocative and significant movement established the dramatic form known as the living newspaper.

Existentialism, a post-World War II movement, is rooted in 19th century philosophy. Related to expressionism, symbolism, and surrealism, its basis is a belief that the important quality in man is his uniqueness. Social pressures threaten the real, the lonely man. His importance, however, is existence itself. Anything but man's real existence is false. Modern man has allowed himself to act as if he were the sum total of social and environmental pressures with his identity forced upon him from without rather than from within. Existentialism asks that a man act from within, from an inner core of being rather than from superimposed ideas. Since each man is unique and each man is changing, he can only act in terms of that inner uniqueness, that inner loneliness. He is, then, not to be concerned with relationships of father, mother, child, society. He is concerned only with being. Jean Paul Sartre is one of the most important exponents of existentialism.

Many important playwrights cannot readily be classified in schools.

Maxwell Anderson, for example, has written many successful plays in verse form; *Winterset, Elizabeth the Queen, High Tor, Knickerbocker Holiday.* Yet, except for T. S. Eliot's *Murder in the Cathedral,* there have been few poetic plays produced. Many exist in book form and in manuscript.

George Bernard Shaw has written plays or scenes in plays that can be fitted into the drama of social protest, impressionism, expressionism, or drawing room comedy. But Shaw has his own characteristic way of looking at the world, so that one speaks of Shavian drama as a school, though Shaw is its only member. Shavian drama is witty, quixotic, penetrating, wise, and concerned with ethical values on a broad scale that transcends national boundaries.

In America, Eugene O'Neill is another writer who defies classification. He is a regionalist in *Beyond the Horizon* and *Desire Under the Elms;* an impressionist in *Emperor Jones;* an expressionist in *Lazarus Laughed, Dynamo, The Hairy Ape;* a symbolist in *The Great God Brown;* a realist in *Anna Christie;* and an experimentalist in his own right in such things as *Mourning Becomes Electra* and *Strange Interlude.*

Schools of drama have always been influenced by the past. With the 20th century came a multiplication of the forms of dramatic expression that influenced theater. To flesh and blood actors in a theater was added the drama of radio, television, motion pictures. These forms give variety and fluidity to dramatic expression and, while they borrow and take their existence from legitimate theater, they also contribute to theater. Dramatic expression in the 20th century has a wider audience and greater global implications than it has had in any previous period in the history of the world. Within this complex and provocative world, the playwright has leaders and schools to follow, but he also has the latitude of further individual growth and experimentation.

Associate Professor of English, University of Washington.

SCHOONAERDE, skōn'är-dĕ, Belgium, in East Flanders on the Scheldt River, in the arrondisement of Termonde. The town is a center for milling and chemical industries, also handmade lace. There are coal mines in the neighborhood. Pop. about 2,215.

SCHOONER. See SAILING VESSELS; SHIP.

SCHOONER RIG, the rigging of a fore-and-aft-rigged vessel. This type of rigging enables a vessel to sail closer to the wind than can a square-rigged ship. Schooner-rigged vessels are also more easily maneuverable and can be handled with smaller crews. The typical schooner of the 18th and early 19th century which engaged in the American coasting trade and, to a lesser extent, in transoceanic trade, was a two-masted vessel, with foresail, mainsail, topsails, staysail and one or more jibs. When a schooner is rigged with a square fore-topsail and topgallant sail, it is called a topsail schooner. About 1840, larger vessels of three or more masts came into use. Since then, down to the early years of the 20th century, American shipbuilders rivaled in the construction of ever larger schooners with more masts and consequently greater area of canvas. Schooners built in the 1880's and 1890's were often of large size, of 2,000 or 3,000-ton burden, and four, five, or even six masts. These schooners were generally constructed for the foreign trade. The only 7-master was the *Thomas Lawson,* 368 feet in length and of 5,200 tons, built at Fore River, Mass., in 1902. Her sails were raised by a donkey engine, making it possible to sail her with a relatively small crew. Few large schooners were built after the first decade of the century. The schooner has always been a favorite and distinctive American rig; but in the 19th century French and English shipyards built schooners. The fishing fleets sailing out of Massachusetts ports were schooners until, in the 20th century, steam replaced sail. The first American yacht to gain fame as a racer was the 65-foot schooner *Wave,* built by John C. Stevens at Hoboken, N. J. in 1832. The *America,* which won the Royal Yacht Squadron race at Cowes in 1851, initiating international yacht races, was also a schooner.

SCHOORLE, SKŌ'RĔL, **SCOREL,** or **SCHOREL, Jan van,** Dutch painter: b. Schoorl, near Alkmaar, Aug. 1, 1495; d. Utrecht, Dec. 6, 1562. At 14 he was placed with the painter Willem Cornelis. Three years later he traveled to Amsterdam, and spent some years in the studio of Jakob Cornelis, one of the most celebrated painters and engravers on wood of that period. He next became a pupil of John of Mabuse, in Utrecht, and subsequently visited

many cities, including Cologne and Spires, where he studied architecture and perspective. He was received kindly by Dürer in Nuremberg. At 22 he passed through Carinthia to Venice, and thence to Palestine. For three years he remained within the walls of Jerusalem sketching views of the city and surrounding country. On his return he spent some time at Rhodes, and afterward at Rome, studying the works of Raphael, Michelangelo and Giulio, till Adrian VI, a native of Utrecht, ascended the papal chair in 1522, and committed to him the superintendence of the Belvedere. The death of Adrian the following year induced Schoorl to return home, which he did by way of France. He now executed many splendid pieces in Utrecht, afterward in Haarlem and from time to time in other cities in the Netherlands. He has been compared with Jan van Eyck, whom he equaled in splendor and truth of coloring, in expression, in warmth of representation; and, at the most, was inferior to him only in the execution of particular parts. Unhappily the rage of the fanatics in a subsequent age for destroying pictures was fatal to many of his most valuable works. Consult Toman, 'Studien über Jan van Scorel' (1889).

SCHOPENHAUER, shō'pĕn-how-ĕr, **Arthur,** German philosopher and man of letters: b. Dantzig, 22 Feb. 1788; d. Frankfort-on-the Main, 21 Sept. 1860. He was of Dutch ancestry on both sides. His father, Heinrich Schopenhauer, was a rich merchant, whose love of freedom was so great that he removed to Hamburg in 1793, when his native city, Dantzig, lost its independence and became a part of Prussia. Schopenhauer's mother, whose maiden name was Johanna Troisner, was a woman of artistic temperament and literary aspirations, some 20 years younger than her husband. After his death in 1805, she removed to Weimar, becoming a member of the literary coterie there, and gaining a reputation as a popular novelist. Heinrich Schopenhauer, proud of his position as an independent merchant, determined that his son should succeed him as the head of the business which he had established. With this object in view, he had him instructed in modern languages, especially in French and English, and took the boy with him on extensive trips through England, France, Holland and Germany, in order to give him a knowledge of the world. When Schopenhauer was 17 his father placed him in a business house in Hamburg. The work was distasteful to him and after his father's death, when he had vainly attempted to accommodate himself to a business career, he decided to follow his bent and devote himself to study. After receiving the necessary preliminary training at Gotha and Weimar, he entered the university at Göttingen in 1809, registering as a student in medicine. Later he studied in Berlin, where he heard lectures from Fichte and Schleiermacher, and finally received the degree of doctor of philosophy from the University of Jena in 1813, on subm tting a thesis on "The Fourfold Root of the Principle of Sufficient Reason." After a residence of several years in Dresden, where he wrote his chief work, 'The World as Will and Idea' (Die Welt als Wille und Vorstellung, 1818), and a visit to Italy, he qualified as private lecturer (*Privat Docent*) in the University of Berlin. He came there with the most extravagant estimate of the importance of his own views, and with the greatest contempt for the prevailing idealistic philosophy, of which Hegel, then at the height of his popularity at Berlin, was the chief representative. Schopenhauer announced lectures at the same hour when Hegel's principal course was given. As a result, his audience was very small; and to make matters worse, his style of lecturing was not popular; his audience fell off and the lectures had to be discontinued before the end of the semester. This embittered him still more, and he imagined that he was the victim of a deliberate plot on the part of various "school philosophers" who had conspired to prevent his views from obtaining a hearing. He made a second visit to Italy, lasting almost three years, but returned to Berlin in 1825, residing here, until 1831, when the epidemic of cholera that carried off Hegel drove him to Frankfort. Here (with the exception of a short stay at Mannheim) he continued until his death. Toward the close of his life his philosophy began to attract popular attention, and Schopenhauer eagerly received the admiration and recognition of a circle of devoted disciples. His old age was the most happy and serene period of his life, though his estimate of his own work was so high that it was not possible to satisfy his demands for recognition and adulation.

Schopenhauer maintains that philosophy cannot be a science; that is, a body of truths derived through logical processes and open to anyone to learn with more or less trouble; but true philosophy is art, a revelation dependent on the intuitive insight of the man of genius. As in the case of a picture or musical composition, one will only perceive in a system of philosophy what one has the capacity to perceive. "There is no one philosophy," says Schopenhauer, "existing or acceptable for everybody. The difference in grades of intelligence is too great for that. The true philosophy, when it makes its appearance, will only command the attention of a few heads of the first order." To the circle of men of genius, then, Schopenhauer confidently claims to belong, and he expresses his contempt for the procedure of the savants who vainly seek philosophical truth by logical processes and accumulations of erudition. For Plato and Kant, Schopenhauer has the greatest admiration and his own thoughts are constantly connected with their ideas. In Plato what attracted him especially was the doctrine of an ideal world and its contrast with the unreality of the world of sensible phenomena. Kant maintained the same contrast and Schopenhauer always claims to be the true successor of Kant, although he replaces the latter's table of 12 categories with the single principle of "sufficient reason," which appears in a fourfold form. With regard to Kant's doctrine that we cannot know the true nature of reality, Schopenhauer also differs from his master. Science is, indeed, limited to the world of phenomena. But we can know the nature of reality by a more direct and intimate method than that which science pursues. In the immediate consciousness of myself I know myself as will; this is the side, the true reality of what appears objectively as body. After the analogy with ourselves everything is to be interpreted: in ourselves,

we have the key that enables us to understand the world. The universe is in itself will. Like the individual, it has its phenomenal side, which can be known by the objective sciences. But its ultimate nature is will, blind, unconscious striving toward existence. The essence of each thing is found in its will. This essence manifests itself in various ways, and with varying degrees of consciousness, from the anconscious manifestations of inorganic forces like gravitation, to the conscious volitions of men.

Though the will is the ultimate source of reality, it creates for itself an external or phenomenal order. This is the order of the intellect, known in terms of the idea, and appearing as an external order of events in space and time which are connected by the principle of cause and effect. So far as the world of phenomena is concerned Schopenhauer is there in fundamental agreement with Kant. That is the realm of scientific knowledge of law and of intelligibility. But behind this as its source and centre is the reality of the irrational will.

The doctrine that the essence of all things is will, is the basis of Schopenhauer's Pessimism (q.v.), just as Hegel's view that reason is the ultimate ground of all things is the foundation of his optimism. Will, for Schopenhauer, is essentially and radically irrational. Under the concept of will he includes all desires, strivings and impulses, all tendencies to change. These, Schopenhauer declares, are all manifestations of dissatisfaction and pain. Our life itself is essentially painful. Pleasure is merely negative, being nothing but the relief arising from the temporary cessation of our pain and desires. Since the will, both in us and in nature, is irrational in its inmost nature, there is no hope of things becoming better. Pessimism necessarily results from insight into the ultimate nature of things. Schopenhauer dwells with extraordinary eloquence on the unspeakable misery of life and upon the aimless striving and irrationality that is everywhere manifested in the world process. But yet, in a way, this insight into the worthlessness of existence brings with it a means of escape. Relief is possible only when the will is stilled and the desires and appetites are silent. Such redemption one can attain in the contemplation of works of art or in listening to music. In this artistic enjoyment our wants cease to exist, the attitude of will is canceled. This relief, from its very nature, can only be transitory. Final redemption from the will must come through ethics. We must perceive that all willing is vain and pleasure unattainable, and also that since individual existence is untrue and only phenomenal, all individuals are at bottom identical in essence, that is, all are manifestations of the one world will. This is to some extent effected through sympathy. There is, however, a higher and more complete virtue than sympathy. It is found in the complete negation of the individual will, the denial of the will to live, based on insight into the nothingness of finite existence. Of this negation of the will we have examples in Christian and Oriental asceticism. This denial of the will is holiness and blessedness in one. It is from the point of view of knowledge Nirvana, nothingness, yet in it the soul finds its highest peace and truest reality.

Bibliography.— A complete edition of Schopenhauer's works, edited by Frauenstadt, appeared in 6 vols. (1873–74; 2d ed., 1877); by J. Giseback (1890); and by Steiner in 13 vols. (1894). His 'Fourfold Root of the Principle of Sufficient Reason' is translated by Hillebrand in the Bohn Library (1894), together with his essay, 'On the Will in Nature.' 'The World as Will and Idea' has been translated by Haldane and Kemp (3 vols., 1884–86). 'The Two Fundamental Problems of Ethics,' translation in Bohn Library by B. Bax; 'The Art of Controversy,' translated by Saunders (1896). Consult also Zimmer, 'Schopenhauer, His Life and Philosophy' (1876); Wallace, 'Life of Arthur Schopenhauer' (1896); Caldwell, 'Schopenhauer's System in Its Philosophical Significance' (1896); Fischer, Kuno, 'Arthur Schepenheuer' (1893); Sully, 'Pessimism' (1891); McGill, V. J., 'Schopenhauer, Pessimist and Pagan' (1931).

JAMES E. CREIGHTON,
Late Professor of Philosophy, Cornell University.

SCHOULER, skoo'lėr, **James,** American lawyer and historian: b. Arlington, Mass., 3 March 1839; d. 16 April 1920. He was graduated from Harvard in 1859, admitted to the bar in 1862, but was obliged to give up his large practice in 1870 because of deafness, caused by service in the Civil War. He then devoted himself to literature almost exclusively until 1884, when he engaged successfully as a lecturer. He was lecturer and professor at the Boston University Law School and at the National University Law School at Washington and in 1891 was appointed lecturer on constitutional law and history at Johns Hopkins, serving until 1908. His publications include 'The Law of Domestic Relations' (1870); 'The Law of Bailments'; 'The Law of Personal Property'; 'The Law of Husband and Wife'; 'Eighty Years of Union' (1904); 'Executors and Administrators' (1883); 'Wills' (1887); 'History of the United States under the Constitution, 1783–1877' (7 vols., 1880–1913); 'Life of Thomas Jefferson' (1897); 'Alexander Hamilton' (1901); 'Americans of 1776' (1906); 'Ideals of the Republic' (1908).

SCHOUTEN, skou'tĕn, **Willem Cornelis,** Dutch navigator: b. Hoorn, c. 1567; d. Madagascar, 1625. For several years previous to 1610 he was in the employ of the Dutch East India Company. He then determined to discover a new route to the Indies and with Jakob Lemaire of Hoorn began the formation of a company with 200,000 florins capital, Schouten's share being one eighth. He sailed in command of an expedition, June 14, 1615, was the first to round the cape which he called Cape Horn and crossed the Pacific to Batavia. Here he was arrested for infringement of the East India Company's privileges; but on his return was acquitted, while the company was fined. He discovered Schouten Islands off the northern coast of New Guinea.

SCHRADER, shrä'dėr, **Frederick Franklin,** American journalist and dramatist, son of an American citizen: b. Hamburg, Germany, Oct. 27, 1857. Author of plays, *The Man from Texas, The Modern Lady Godiva, At the*

French Ball,' 'Nicolette,' comic opera, music by Irenée Bergé, translated into Bohemian and produced in New York, 25 Dec. 1915; 'Corsica,' music drama in one act, music by Irenée Bergé, produced in 1910; lyrist of 'Baron Trenck,' produced in London 1911 and New York 1912. Translator of Max Nordau's, 'Freie Liebe' ('Paris Sketches'), and 'José,' novel, by Otto Ruppius. Assistant and Acting Secretary, Republican Congressional Committee, 1896–1900; author of Republican Text Book 1898. Dramatic editor Washington *Post* 1901–06; on literary staff, David Belasco 1906–09; dramatic editor New York *Globe,* 1909–10; editor New York *Dramatic Mirror* and president publishing company, 19 Aug. 1912 to 9 Sept. 1916. Co-founder with George S. Viereck of *The Fatherland,* August 1914; editor of *Issues and Events.*

SCHRADER, Julius, German painter: b. Berlin, 16 June 1815; d. Lichterfelde, 16 Feb. 1900. He studied at the Berlin Academy and at Düsseldorf under Schadow, 1837–45. Subsequently he traveled in Italy, England, Holland and Belgium and in the last country fell under the influence of the colorists Gallait and Biefoe. In 1851 he became professor at the Berlin Academy. Among his chief works are 'Surrender of Calais to Edward III' (1847); 'Frederick the Great after the Battle of Kolin' (1849); 'Death of Leonardo da Vinci' (1851); 'Milton and His Daughters' (1855); 'Cromwell at the Death-Bed of His Daughter' (1859). In fresco he painted 'First Twelve Christian Monarchs' in the Royal Chapel, and 'Consecration of the Church of Saint Sophia, Constantinople' in the New Museum, Berlin. Among his portraits are those of Humboldt and Ranke, the historian.

SCHREIBER, shrī'bĕr, **Sir Collingwood,** Canadian railway engineer: b. Essex, England, 1831; d. 1918. He settled in Canada in 1852 and engaged in engineering at Toronto. He was assistant engineer of the Toronto and Hamilton Railway in 1852–56; superintending engineer of the Northern Railway in 1860–62; division engineer for the Nova Scotia government in 1863–67; and in 1867–73 he had charge of the surveys of the Intercolonial Railway and was chief engineer of the government railways in operation. He was appointed chief engineer of the Canadian Pacific in 1880; became chief engineer and Deputy Minister of the Department of Railways and Canals, Ottawa; and in 1905 he was appointed consulting engineer to the Canadian government and chief engineer of the western division of the National Trans-Continental Railway. He was knighted in 1916.

SCHREINER, shrīnĕr, **Olive** (better known by name of Olive Schreiner Cronwright), pseudonym "Ralph Iron," South African author: b. Basutoland 1862; d. 1920. In 1883 appeared "Ralph Iron's" first work, 'The Story of an African Farm,' a book of much interest with simple yet forceful pictures, from the Boer country. Further publications are 'Dreams' (5th ed., 1893); 'Dream Life and Real Life' (1893); 'Trooper Peter Halket of Mashonaland' (1897); and 'An English South African's View of the Situation' (1899); a critique on the Transvaal difficulty from the pro-Boer position. She was married in 1894 to S. C. Cronwright. Her posthumous novel, 'From Man to Man,' was published in 1927.

SCHREINER, Oswald, American agricultural chemist: b. Nassau, Germany, 29 May 1875. He was graduated at the Baltimore Polytechnic Institute in 1892, the Maryland College of Pharmacy in 1894, and later studied at Johns Hopkins University and at the University of Wisconsin. He was United States Pharmacopœia Research Fellow in 1895–96, and in 1903 was appointed chemist of the United States Bureau of Soils. From 1906 he was chief of the Division of Soil Fertility Investigation; and in 1914 he was appointed consulting professor of chemistry at the American University. He has prepared many of the bulletins of his department and is also author of 'The Sesquiterpenes' (1904); 'Chemistry of Soil Organic Matter' (1910); 'The Nitrogenous Soil Constituents' (1913), etc.

SCHREYER, shrī'ĕr, **Adolf,** German artist: b. Frankfort-on-the-Main, 9 May 1828; d. Kronberg, Prussia, 29 July 1899. He studied at the Städel Institut, Frankfort, then at Stuttgart, Munich and Düsseldorf and supplemented this school instruction by wide travels in Europe and the East. In 1862 he became court-painter to the Grand Duke of Mecklenburg-Schwerin. He was a member of the academies of Antwerp and Rotterdam. Before 1870 he lived much at Paris; but after that year lived alternately there and at Kronberg. He was an animal painter, especially choosing the horse for his model and depicting it in vigorous action or, when held in rein, with pawing feet and distended nostril. He was, also, a follower of Fromentian in his love of Eastern subjects, particularly mounted Arabs dressed in brilliantly colored clothes, surrounded by a heated palpitating atmosphere. Some of his pictures are 'Artillery attacked by Prussian Hussars' (1854); 'Wallachian Transportation Train in Rainy Weather,' at Hamburg; 'Charge of Artillery of the Imperial Guard' (1865); 'Horses of the Irregular Cossacks' (1864) at Paris. His 'Battle near Waghensel, in 1849' (1858); 'Battle of Komorn,' 'An Attack of Cavalry,' and 'Prince Thurn and Taxis wounded at Temisvár' are among his best-known pictures, but are lodged in private galleries in Europe. Many canvases by Schreyer are to be found in the private collections of the United States, such as the Walters, the Vanderbilt, the Astor and the Huntington galleries. 'The Watering Place' is at the Corcoran Gallery at Washington.

SCHROEDER, shrē'dĕr, **Seaton,** American rear-admiral: b. Washington, D. C., 17 Aug. 1849. He was graduated at the United States Naval Academy in 1868, and accompanied Commodore Rodgers' expedition against the Korean forts in 1871. He was on special duty supervising the construction of the dynamite cruiser *Vesuvius* in 1888–90, and was in command of that ship in 1890–93. He was executive officer of the *Massachusetts* in 1897–99, and was advanced three points in rank for his services in the Spanish-American War. He was naval governor of the island of Guam and commander of the *Yosemite* in 1900–03; attained rank as rear-admiral in 1908, and was in charge of a division of the Atlantic fleet in 1908–09. From March 1909 until June 1911 he

was commander-in-chief of the Atlantic fleet. He then served on the General Board until 17 Aug. 1911, when he was retired upon reaching the age limit. He was retained on special service with the navy in 1911–14; and in 1917 was appointed hydrographer. Author of many essays and of 'Fall of Maximilian's Empire' (1887). Died Washington, D. C., 19 Oct. 1922.

SCHUBART, shoo'bärt, **Christian Friedrich Daniel,** German poet: b. Obersontheim, Swabia, 26 March 1739; d. Stuttgart, Germany, 10 Oct. 1791. He studied theology at Jena where he lived a dissipated life, and became musical director at Ludwigsburg in 1758, but was banished because of his dissolute conduct. After years of wandering he founded his *Deutsche Chronik* at Augsburg in 1774, but was driven thence in 1777 and removed his *Chronik* to Ulm. He there published a false report of the death of Maria Theresa and was imprisoned for 10 years when he was released at the demand of Frederick the Great in 1787. He then became musical and theatre director in Stuttgart and continued the publication of his paper under the title *Vaterlands-Chronik.* He wrote 'Gedichte aus dem Kerker' (1785); 'Hymnus auf Friedrich den Grossen' (1786), etc. His 'Gesammelte Schrifte und Schicksale' was published in eight volumes (1839–40). Consult Strauss, 'Schubart's Leben in seinen Briefen' (1849).

SCHUBERT, shoo'bĕrt, **Franz Peter,** Austrian composer: b. Vienna, 31 Jan. 1797; d. there, 19 Nov. 1828. His extraordinary musical gifts were displayed at a very early age, and his talents were so pronounced that his teachers had little else to do but kindle the ever-present though dormant spark.

Before he was 11 years old he was the leading soprano in the Lichtenthal choir, and he also played the violin solos in the services, besides composing songs and pieces for strings and piano. In his 12th year he entered the Imperial Convent, or school for educating choristers for the court chapel. His first piano composition, dated 8 April–1 May 1810, appears to have been a four-hand Fantasia, containing a dozen or more movements. While at the "Convent" he composed his first symphony, in D, in connection with the celebration of the birthday of Dr. Lang, the director of the school. His voice breaking, he returned home about the end of October 1812, in which year his mother died. He then joined his father in school work and for three years taught the primary class. Apart from his school duties he naturally devoted himself to composition, especially in the direction of setting words to music, to which he gave himself up with tremendous enthusiasm. His melodies seemed to be endless, his songs sprang into existence and poets could scarcely write down their verses before Schubert had them set to music. In the intervals snatched from his regular duties he found time to write eight operas, four masses and other sacred works, besides a great number of songs. In 1817 he was enabled to throw off the fetters of his school work through the generosity of his friend Schober. From this time till his death there was only one brief decade, but the number of his compositions during that time is stupendous. He composed with the greatest ease and rapidity, and it is said that he could readily keep up a conversation while writing even his best pieces. He never hesitated, and seldom revised anything he wrote. His compositions included more than 70 part songs, some 18 works for the stage, 8 sacred pieces, 20 string quartets, 10 symphonies, and 24 pianoforte sonatas, but after all it was not through these that Schubert's name was immortalized, but through his songs, the titles of nearly 500 of which are recorded. They were full of dramatic intensity, poetry and pathos, and full of music of infinite beauty set to long, complex poems, to which he arranged accompaniments of complete fitness and endless variety.

His engagement as teacher of music in the family of Count Esterhazy during the summer of 1818, at Zselész, was the source of his first regular income. There were two daughters in the Esterhazy family, Marie and Caroline, and a little boy of five. The congenial occupation of teaching them was renewed later, in 1824, at which time he composed his 'Grand Duo' (opus 140), full of individualism and truly a symphonic work in its fullest sense. During that summer he also composed his sonata in B flat, the variations in A flat, and a number of other pieces, presumably for use in the musical education of the Count's children.

To attempt to even mention any considerable number of Schubert's compositions here is manifestly impossible, but very complete lists of his works, arranged both alphabetically and also in the order of their composition, may be found in Grove's 'Dictionary of Music.'

One of Schubert's closest friends was Vogl, the tenor, through whose influence the attention of theatrical managers was attracted toward him. He had already written a comic operetta, the 'Zwillingsbrüder,' for the Kärntnerthor theatre, and not long after he was commissioned by a rival theatre to write the music for the 'Zauberharfe,' or 'Magic Harp,' which he is said to have completed in two weeks, and which was first performed on 19 Aug. 1820 in the Theater an-der-Wien. During this year, too, he wrote several of his best songs, including the famous 'Im Walde' or 'Waldesnacht.'

In the following February, when Schubert was entering his 25th year, his talents began to receive recognition, and the publication of his songs was at last within sight. The 'Erl King' was chosen first and was published (on commission) on 1 April 1821, enough money having been subscribed at one of the Gundelhoff concerts to defray the cost of printing, engraving, and still leave something over for future publications. Seven more songs (constituting op. 3 and 4) were published on 29 May, op. 5 on 9 July, op. 6 on 23 August and op. 7 on 27 November. The next appeared on 9 May 1822, as "the property of the publishers," who now stopped publication by commission realizing that they could assume the responsibility without risk.

In August 1821 he began his symphony in E, which, although he did not complete the writing of it, is remarkable for the rapidity with which it was composed. It is said that he probably did not occupy himself with it for more than a few hours, and yet it filled 167 pages. A month or two later he wrote two acts of 'Alfonso and Estrella,' the words being

supplied by Schober. The third act was finished in February 1822, but no public performance of it was given until 26 years after Schubert's death, one cause of this delay being that the original accompaniments proved impossible for a band to play. During 1823 Schubert paid special attention to operatic music but without marked success, perhaps because the librettos were unsuitable. On this point Liszt regarded it as extraordinary that one who had been brought up to love the finest poetry should accept the absurd and impracticable librettos which were offered him, and which resulted in so much of his brilliant music being practically lost to the world. It was in this same year that his famous «Müller-lieder» were composed, consisting of musical settings to Wilhelm Müller's poems, a copy of which he had borrowed from his friend Randhartinger when visiting him.

The rejection of his opera 'Fierabras' in 1824 filled him with distress, from which however he was aroused by the quiet joys of his second stay with the family of Count Esterhazy at Zselész. During these happy days he probably wrote his lovely string quartet in A minor and the 'Divertissement à la Hongroise' for four hands, as well as several other pieces already mentioned.

Some of his best compositions in 1826 were the string quartet in D minor and G, the 'Rondeau brilliant,' as well as the sonata in G major, which Schumann regarded as his «most perfect work both in form and composition.» The number of pieces published in that year was very large, showing that a popular demand for his music had arisen, but nevertheless Schubert was always poor, partly because his profits were so small, and partly because he allowed himself to be imposed upon by his friends.

The year of 1827 was notable as the one in which Beethoven died. He and Schubert had not been intimate, and the latter's visit to Beethoven in 1822 had ended disastrously, for on looking over the 'Variations' Beethoven had pointed out something which astonished him, whereupon Schubert is said to have lost his self-control and to have rushed from the room. In April of this year was written the beautiful 'Nachtgesang im Walde' for four men's voices and four horns, and a spring song for men's voices. In this year he was elected a member of the Musical Society of Vienna, which gave him considerable satisfaction.

The last year of Schubert's life, 1828, was remarkable for the number of his compositions, among which, writes Grove, were «his greatest known symphony (in C), his greatest and longest Mass, his first Oratorio, his finest piece of chamber music, three noble pianoforte sonatas, and some astonishingly fine songs.» On 26 March he gave his first evening concert in the hall of the Musik-Verein. The program was very attractive and the applause great. In the month before he died he wrote a new 'Benedictus' to one of his Masses, wind-accompaniments to his 'Hymn to the Holy Ghost,' a long scena for a soprano voice, and a song entitled 'Die Taubenpost,' which is thought to have been his last composition. He was buried, in accordance with his dying wishes, in the Ortsfriedhof in the village of Währing, and in a grave only separated by two others from the one which held the remains of Beethoven.

Schubert's most prominent characteristics were truthfulness, honesty, good-humor and a cheerful, contented disposition. With his intimates he was entirely at ease, genial and even boisterous at times, but at a fashionable gathering he was shy and silent. Of his musical genius no better description can be given than in the words of Liszt: «He was the most poetical musician that ever was; and the main characteristics of his music will always be its vivid personality, fullness and poetry. In the case of other great composers, the mechanical skill and ingenuity, the very ease and absence of effort with which many of their effects are produced, or their pieces constructed, is a great element in the pleasure produced by their music. Not so with Schubert. In listening to him one is never betrayed into exclaiming 'how clever'; but very often, 'how poetical, how beautiful. how intensely Schubert.'» Consult Ferris, 'The Great German Composers' (1878); Kreissle von Hellborn, 'Franz Schubert, eine biographische Skizze' (1861–65; Eng. trans. 1869); Reissmann, 'Franz Schubert, sein Leben und seine verse' (1873); Barbedette, 'Franz Schubert, Sa vie, ses œuvres, son temps' (1866); Frost, 'Schubert' (1888).

SCHUCHERT, shŭk'ĕrt, **Charles,** American palaeontologist: b. Cincinnati, Ohio, 3 July 1858. He received a common school education, but possessing a natural aptitude for scientific investigation he early began a collection of fossils and the study of palaeontology. He was assistant to different experts in 1885–91; and in 1891–92 assisted in the geological survey of Minnesota. He was preparator of fossils with Dr. C. E. Beecher at Yale in 1892–93; served on the United States Geological Survey in 1893–94; and from 1904 to 1923 he was professor of palaeontology and Yale professor of the history of geology at Sheffield Scientific School, and curator of the geological collections at Peabody Institute. Author of 'Textbook of Geology'; 'Historical Geological Paleograph of North America'; 'Revision of Paleozoic Stelleroida, with Special Reference to North American Asteroida' (1915). Died, 21 Nov. 1942.

SCHULMAN, shool'man, **Samuel,** American rabbi: b. Russia, 14 Feb. 1864. He came to America as a child, was graduated at the College of the City of New York in 1885 and studied at the University of Berlin in 1885–89. He was rabbi at Helena, Mont., in 1890–93; at Kansas City, Mo., 1893–99; 1899–1927 rabbi of Temple Beth-El (now Emanu-El), New York. He was a member of the board of editors for the English translation of the Bible for the Synagogue; a contributor to the 'Jewish Encyclopedia'; and is author of articles on religious topics.

SCHULTZ, shŭlts, Sir **John Christian,** Canadian administrator: b. Amherstburg, Ontario, 1 Jan. 1840; d. Winnipeg, 13 April 1896. He was educated at Oberlin College, Ohio; Queen's University, Kingston; and at Victoria University, Cobourg, taking his M.D. in 1860. He then engaged in practice at Winnipeg (then Fort Garry), also becoming interested in the fur trade and editing the *Nor'wester,* the first newspaper of the region. He led the Canadian

party at the time of Louis Riel's first uprising (1869–1870), was taken prisoner, and sentenced to death by Riel. Having escaped, he continued his political career, became a member of the North West Council (1872), a member of the Dominion Parliament (1871–1882), a Dominion senator (1882–1888), and from 1888 to 1895 lieutenant governor of Manitoba. In 1895 he was knighted.

He was interested in railway and telegraphic development and in colonization, and was for many years a member of the Dominion Board of Health for Manitoba.

SCHULTZ LAKE, lake, Northwest Territories, Canada, in the central Keewatin District, is 35 miles long and 11 miles wide, with an area of 110 square miles. It is drained by the Thelon River, which flows into Baker Lake.

SCHULTZE, shŏŏlts, **Carl Emil** (pseudonym BUNNY), American cartoonist: b. Lexington, Ky., May 25, 1886; d. New York, N. Y., Jan. 18, 1939. He was educated at Lexington and at Cassel, Germany, began drawing for newspapers, and under the name of "Bunny" created the popular *Foxy Grandpa* series of comic pictures published in the New York *Herald* (1900–1902) and the New York *American* (from 1902). Most of them were republished in a series of *Foxy Grandpa* books. From 1923 to 1927 he was president of the International Feature Service of the New York *Evening Journal.* He is the author of *Vaudevilles and Other Things* (1900) and *The Adventures of Foxy Grandpa* (1900).

SCHULTZE, shŏŏl'tsĕ, **Max Johann Sigismund,** German anatomist: b. Freiburg, Germany, March 25, 1825; d. Bonn, Jan. 16, 1874. A professor at Halle University (1854), Schultze became in 1859 director of the anatomical institute at Bonn. His research was mainly in the microscopic examination of protoplasm, protozoa, and cells, and in the nerve endings of eye, ear, and nose. His discoveries contributed to a new understanding of the structure and functioning of the cell. With others, he was a founder in 1865 of *Archiv für Mikroskopische Anatomie.*

SCHULTZE-NAUMBURG, -noum'bŏŏrĸ, **Paul,** German architect and writer: b. Naumburg, Germany, June 10, 1869. After studying at the Kunstakademie in Karlsruhe, Schultze-Naumburg went to teach art in Weimar (1893), where he became one of the new Secessionists (q.v.), an advanced group in art. He wrote *Studium und Ziele der Malerei* (*The Study and Aims of Painting,* 1900) to explain the movement, but he was never considered a true Secessionist. He turned to painting his own Thuringian countryside attempting to make an imaginative reconstruction rather than an exact reproduction. Twilight was his favorite painting light. Next he became interested in applied art, and was in the forefront of his time. He wrote *Häusliche Kunstpflege* (*The Study of Domestic Art,* 1902), explaining that articles for domestic use were artistic if they perfectly expressed their function. His next phase was his most famous. He became a decorative artist, making all his pictures part of the decorative treatment of a room.

SCHULZ or **SCHULTZ,** shŏŏlts, **Johann Abraham Peter,** German organist, conductor, and composer: b. Lüneburg, Germany, March 31, 1747; d. Schwedt, June 10, 1800. At 15 Schulz left home to study with Johann Philipp Kirnberger in Berlin. As accompanist and music instructor to the Polish Princess Sapieha, he traveled through Europe in 1768, returning to Berlin in 1773. From 1776 to 1778 he was orchestral conductor in the French theater in Berlin, and for seven years (1780–1787) in the private theater of Prince Henry of Prussia. The king of Denmark liked his incidental music to Jean Baptiste Racine's *Athalie* so much that he invited Schulz to be court conductor at Copenhagen (1787–1795). He wrote not only operas, oratorios, music for plays, and large numbers of songs, but also a book on musical theory. It is his settings to contemporary poems that are considered of lasting value.

SCHULZ, Leo, American cellist: b. Posen, Germany, March 28, 1865; d. La Crescenta, Calif., Aug. 12, 1944. His musical education was at the Berlin Hochschule. He gave his first public recital at the age of five and appeared as a professional performer in 1876. By 1885 he was first cellist in the Berlin Philharmonic Orchestra and in 1886–1889 in the Gewandhaus Orchestra at Leipzig. He was a member of the Boston Symphony Orchestra in 1889, thereafter of the New York Philharmonic Society for many years, during which he also taught at the National Conservatory and conducted its orchestra. From 1904 to 1915 he was a member of the Margulies Trio. Among his compositions were chamber music, a cello concerto and other pieces for cello, a cantata, and songs.

SCHULZE-DELITZSCH, shŏŏl'tsĕ dā'-lĭch, **Hermann** (in full FRANZ HERMANN SCHULZE-DELITZSCH), German lawyer, politician, and economist: b. Delitzsch, Germany, Aug. 29, 1808; d. Potsdam, April 29, 1883. After legal courses at Leipzig and Halle, he entered the Prussian public service, and, except for a period of 10 years, was a member of the Prussian legislature from 1848 until his death. His energies were devoted, among other things, to bettering the lot of laborers, artisans, and small tradesmen. Toward this end he organized mercantile and consumers' cooperatives and founded the "people's banks," in which the members elected the managerial boards and received credit and dividends in proportion to their deposits. In 1859 more than 200 such banks were centrally organized under the direction of Schulze-Delitzsch, and at the time of his death there were in Germany alone 3,500 branches, with more than $100 million in deposits. The system spread widely in Europe.

SCHULZE-GAVERNITZ, Hermann Johann Friedrich von, German legal scholar: b. Jena, Germany, Sept. 23, 1824; d. Heidelberg, Oct. 28, 1888. Appointed professor at Jena in 1850, he transferred to Breslau seven years later, and taught at Heidelberg from 1878. His most important works were *System des deutschen Staatsrechts* (1865) and *Das preussische Staatsrecht . . .*, 2 vols. (1872–1877). He was ennobled in 1888.

GERHART VON SCHULZE-GÄVERNITZ (1864–1943), his son, was professor of economics at Freiburg from 1893 to 1926, and sat in the Reichstag as a member of the Progressive People's Party (1912–1920, 1922). He was the author of a number of works on English economic and social history.

SCHUMACHER, shōō'mȧ-kĕr, **Fritz,** German architect and city planner: b. Bremen, Germany, Nov. 4, 1869; d. Hamburg, 1947. Schumacher lived abroad with his family until 1884, when they returned to Bremen. He studied at the Munich and Berlin technical schools. From 1895 to 1899 he was an architect for Leipzig; then professor of architecture at Dresden Technical High School (1899–1909); and director of city planning in Hamburg (1909; 1924–1939), which he made into a modern city. Brick construction was his distinctive form. He was responsible for city planning in most of the great German cities, and designed schools, parks, and municipal buildings. He wrote *Das Wesen des neuzeitliche Backsteinbaus* (1920); *Strömungen in deutscher Baukunst seit 1800* (1935); and *Der Geist der Baukunst* (1938).

SCHUMACHER, Heinrich Christian, Danish astronomer: b. Bramstedt, Holstein, then a part of Denmark, Sept. 3, 1780; d. Altona, Dec. 28, 1850. Schumacher studied law at the universities of Kiel and Göttingen and taught at Dorpat, but a change of interest took him to Göttingen again to study astronomy. In 1810 he was given a teaching post at Copenhagen, in 1813 became a director of the Mannheim Observatory, and in 1815 was made professor of astronomy and director of the observatory at Copenhagen. But most of his time was given to the observatory the king had built for him (1823) at Altona, near Hamburg. Though he accomplished a good deal of distinguished work in astronomy during his lifetime, he is best known today for the important scientific periodical *Astronomische Nachrichten,* which he launched in 1821 and which still has an international circulation.

SCHUMACHER, Hermann, German economist: b. Bremen, Germany, March 6, 1868. The brother of Fritz Schumacher (q.v.), he also lived abroad, and received his early education in New York City; but he went to the Bremen Gymnasium and the universities of Freiburg, Munich, Vienna, and Berlin. The Imperial Chancery made him a grant to study the American cereal trade, and he published a book on the subject (1895). He was sent on a commission to study industrial conditions in Asia; in 1899 he became professor at the University of Kiel; in 1901 director of the Cologne School of Commerce; in 1904 professor at Bonn; and in 1917 at Berlin. Among his works are books on the tariff, on industry, American finance, socialism, international trade, and international problems. He was the first German exchange professor at Columbia University (1906).

SCHUMACHER, Kurt Ernst Karl, German politician: b. Kulm (now Chelmno, Poland), Pomerania, West Prussia, Oct. 13, 1895; d. Bonn, Germany, Aug. 20, 1952. A student in law at Münster when World War I broke out, Schumacher served only six months before losing his right arm. He continued to study for a doctorate at Munich while working at the ministry of labor in the Weimar Republic. He organized disabled veterans and became the leader of the Social Democratic Party (SPD), editing its paper, *Schwäbischen Tagwacht.* From 1924 to 1931 he was a member of the Prussian Diet, and from 1930 to 1933 deputy from Württemberg to the Reichstag.

His opposition to the Nazis put him in a concentration camp in 1933, where he stayed until 1942, released because of ill-health. When the war ended he was well enough to continue his political activities, and obtained permission from the British West Zone officials to revive the Social Democratic Party. It soon became the second political group in West Germany. In 1946 he was chosen party chairman. He agitated for a unified Germany free from any foreign entanglements, and lost the elections in 1949 by a very small margin. In 1948 his leg was amputated, as a result of his treatment in the prison camp.

SCHUMACHER, shōō'măk-ŭr, town, Ontario, Canada, in the northeastern part of the province, two miles east of Timmins. It is in a gold-mining region. Pop. (1951) 3,002.

SCHUMAN, shōō'măn, **Frederick Lewis,** American political scientist and writer: b. Chicago, Ill., Feb. 22, 1904. After serving as instructor (1927–1932) and as assistant professor (1932–1936) of political science at the University of Chicago, Schuman became professor of political science at Williams College in 1936 and Woodrow Wilson professor of government in 1938. He has been visiting professor at many universities, a lecturer and contributor to magazines, foreign broadcaster for the Federal Communications Commission (1942–1943), and a fellow of the Foundation for World Government (1950–1951). Among his published works are *International Politics* (1933; 5th ed. 1953); *The Nazi Dictatorship* (1935); *Night Over Europe* (1941); *Soviet Politics* (1946); and *The Commonwealth of Man* (1952).

SCHUMAN, shōō'măn, **Robert,** French statesman: b. Luxembourg, Grand Duchy of Luxembourg, June 29, 1886. He spent his early years in Lorraine, then a province of Germany, attended German universities, and began the practice of law in Metz. Because he refused to serve in the German Army in World War I, he spent the war years in a German prison. In 1919, when Lorraine was returned to France, he was elected a deputy from Moselle to the French Chamber. In 1940 the Vichy government made him under secretary of state for refugees, but he was arrested by the Gestapo in September. He managed to escape. One of the founders of the MRP (Mouvement Républicaine Populaire), he was elected deputy for the party in 1945. He became finance minister in 1946 and again in 1947, and in November of that year was chosen premier. Strikes were settled in a few weeks, but he lost power in July 1948 over his military budget. In August he again became premier—to serve until September. He next headed the French delegation to the United Nations General Assembly. From 1948 to 1952 he was foreign minister in all cabinets, but refused to serve in the cabinet of Pierre Mendès-France because of the chamber's refusal to ratify EDC (European Defense Community), which he ardently supported. In 1950, while foreign minister, he sanctioned the European Coal and Steel Community (q.v.), unofficially called the Schuman Plan. In February 1955 he became minister of justice in the cabinet of Edgar Faure.

SCHUMAN, William, American composer and teacher: b. New York, N. Y., Aug. 4, 1910. Schuman was graduated from Columbia University in 1935, and after studying with the American teachers Charles Haubiel, Max Persin, and Roy Harris, went to Salzburg to the Mozarteum Academy. Upon his return he taught at Columbia in the summer session (1936) and at Sarah Lawrence

College (1935–1944). He was awarded two Guggenheim Fellowships for composition (1939–1940; 1940–1941); the first Pulitzer Music Prize (1943) for his *Secular Cantata No. 2, A Free Song* (1942); the first Town Hall-League of Composers Award (1942) for *Spring Quartet No. 3*, and numerous other awards. *American Festival Overture* (1939) was given its first performance by the Boston Symphony Orchestra; *Prayer in Time of War* (1943), a first performance by the Pittsburgh Symphony Orchestra; *William Billings Overture* (1943) by the New York Philharmonic Orchestra. His ballet *Undertow* was performed by the Ballet Theatre Company at the New York Metropolitan Opera (1945). In 1945 he became president of the Juilliard School of Music.

Consult Schreiber, F. R., and Persichetti, V., *William Schuman* (New York 1954).

SCHUMAN PLAN, The. See EUROPEAN COAL AND STEEL COMMUNITY.

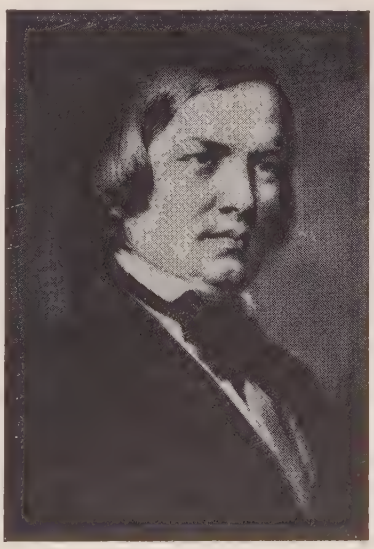
SCHUMANN, shōō'män, **Clara Josephine** (nee WIECK), German pianist and composer: b. Leipzig, Germany, Sept. 13, 1819; d. Frankfurt am Main, May 20, 1896. The daughter of the pianist Friedrich Wieck, from whom she received instruction for 15 years, she took part in a public concert for the first time in her ninth year. Her musical development was furthered by a concert tour with her father through the musical centers of Germany and France (1831–1832). She was the first to bring Frédéric Chopin's works to the notice of the German public. In 1840 she married Robert Schumann (q.v.), and shared his work and European successes until his death in 1856. Thereafter she pursued her public career alone, devoting much of her effort to furthering recognition of his genius. In 1878 she was appointed principal teacher of the pianoforte in the conservatory at Frankfurt am Main, where she remained until her retirement (1892).

SCHUMANN, Georg (Alfred), German composer, violinist, organist, and conductor: b. Königstein on Elbe, Germany, Oct. 25, 1866; d. Berlin, May 23, 1952. His father and grandfather, musicians also, taught him to play the violin and the organ, on both of which he performed as a child. From 1881 to 1888 he studied at the Leipzig Conservatory. He was conductor of a choral society at Danzig (1891–1896); director of the Philharmonic Orchestra and choir at Bremen (1896–1899); professor and head of the Berlin Singakademie (1900); head of the composition school of the Academy of Arts (1913). His choral works include *Amor und Psyche, Totenklage,* and *Sehnsucht;* his *Symphony in B minor* won a prize, and his oratorio *Ruth* was given at the Sheffield Festival in 1911. He also composed chamber music and works for orchestra, piano, and organ.

SCHUMANN, Maurice (pseudonym ANDRÉ SIDOBRE), French journalist and political leader: b. Paris, France, April 10, 1911. Between 1932 and 1940 Schumann was with the Havas News Agency in London. At the beginning of World War II he became a broadcaster for the British Broadcasting Company's French service, and from D-Day 1944 until the liberation of Paris he was liaison officer with the Allied Expeditionary Forces. Chosen a member of the French Provisional Consultative Assembly of November 1944–July 1945, he served in the Constituent Assembly in 1945 and in 1946. He was chairman of the Mouvement Républicain Populaire (MRP), deputy in the National Assembly (1951), and secretary for foreign affairs. A contributor of editorials to *L'Aube*, the Paris daily, he also published *Le germanisme en marche* (1938); *Mussolini* (1939); *Honneur et Patrie* (1946).

SCHUMANN, Robert, German composer: b. Zwickau, Saxony, Germany, June 8, 1810; d. Endenich, near Bonn, July 29, 1856. His father, who encouraged him in his career, was a bookseller and an author of some note. Robert engaged in a desultory study of law at Leipzig and Heidelberg, and by the age of 16 had finished a novel. But the youth who had written for the orchestra at the age of 12 and had turned out numerous compositions thereafter, including songs written to his own words, could now thwart his genius no longer. At 20 he began serious study of the piano under Friedrich Wieck, who already had instructed him, and Heinrich Dorn. An unwisely chosen method of his own, intended to free the fourth finger, resulted in the crippling of one of the fingers of his right hand. He had to give up any idea of becoming a pianist, and thenceforward devoted himself to composition. In 1834 he assisted in founding, and until 1844 edited, a musical journal, *Die Neue Zeitschrift für Musik*, for advancing the art and emancipating it from old-fashioned methods and from French and Italian influences. Convinced that German art had not yet reached its full development, he said: "Consciously or unconsciously, a new and as yet undeveloped school is being founded on the basis of the Beethoven-Schubert romanticism, a school which we may venture to expect will mark a special epoch in the history of art."

Meanwhile Schumann was busy composing in a variety of forms. In 1833 he published his first *Impromptus* (Op. 5). In this year, too, he began his *Sonata No. 1 in F minor* (Op. 11). A turning point was reached in his life in October 1835 when Felix Mendelssohn and he met at a musical gathering at Wieck's. A strong intimacy seems to have grown up between them. Schumann declared that Mendelssohn was the greatest living musician and that he seemed like a "high mountain peak." Mendelssohn saw in Schumann only the literary man and art critic, but it is significant that when, in 1843, Mendelssohn established the Leipzig Conservatorium, Schu-



Robert Schumann.

mann was appointed teacher of playing from score. While there he introduced the use of the piano with pedals as a preparation for playing the organ.

Schumann's marriage in 1840 to Clara Wieck, daughter of his old teacher, was apparently a very happy one, and the fact that he soon afterward began to compose love songs does not weaken this belief. At the same time his wife regarded it as her greatest privilege to interpret his compositions faithfully to the public, nor was it long before she became the leading woman pianist of Germany. In the year after his marriage he paid more special attention to symphonic work, composing three entire numbers, only one of which, however — in B♭ — was published at that time. He also wrote the first movement of the 'Pianoforte Concerto in A minor.' In 1842 Schumann accompanied his wife on a concert tour to Hamburg. The latter proceeded alone from there to Copenhagen, while he returned to Leipzig. Later they visited Bohemia and met Prince Metternich, at whose invitation they went to Vienna. In 1844 they traveled to Russia, Madame Schumann giving concerts in several of the large cities; but Schumann, who loved the quiet of domestic life, was always impatient to return home.

The style of Schumann's compositions underwent a decided change in 1843, the principal work of the year being 'Paradise and the Peri,' for solo voices, chorus and orchestra. It was first performed on 4 December, and was conducted by Schumann in person. He also composed his popular 'Variations' for two pianos (op. 46), and from this time his reputation in Germany was firmly established. Thus encouraged he began in the following year the second of his two most famous choral works consisting of a musical setting to Goethe's 'Faust.' About this time he gave up the editorship of his paper and changed his residence to Dresden, where he at first lived in seclusion on account of his nervous condition, resulting doubtless from overwork. In 1845–46 he composed his 'Studies' and 'Sketches' for the pedal-piano, as well as his famous 'C major Symphony,' first produced by Mendelssohn at the Gewandhaus in Leipzig, 5 Nov. 1846. In Dresden he met Richard Wagner, for whose work he expressed great admiration, but on account of their very different natures they were never in close sympathy. The former was high-spirited and talkative, while Schumann, always reserved, was growing more and more silent. The idea of the improvement of German operatic music, long a favorite subject with Schumann, now led him to write an opera. He chose as his subject the legend of Saint Geneviève, but only after long and irritating delays was the first performance of 'Genoveva' arranged. This took place on 25 June 1850 under Schumann's own direction. The criticisms of this first attempt at dramatic work were on the whole unfavorable, and it is said that he derived far more gratification from the reception accorded to his music of 'Faust.' He also wrote an excellent musical setting for Byron's 'Manfred,' which had its first performance in Weimar 13 June 1852.

While living in Dresden he undertook the direction of the Liedertafel, and in 1848 he established a choral society. Two years later he accepted the position of municipal director of music at Düsseldorf. Here he had the direction of a vocal organization and an orchestra. His duties were sufficiently light, however, to leave him ample time for social enjoyment, in which he took great pleasure. His generous nature was manifested by his arrangement of a series of concerts, some of which were devoted wholly to the works of other living composers. This was in line with his desire to aid in advancing the interests of those less famous than himself. As a conductor Schumann was not regarded as a success. His lack of presence of mind and of sympathy with the players was conspicuous and contributed largely to his unpopularity as a leader. This unfortunate condition of things, combined with the return of a brain affection, symptoms of which had been first manifested as far back as 1833, at length made it necessary for him to resign his post, which he did in 1853. During his residence in Düsseldorf the number of his compositions was very great, including the celebrated 'E♭ Symphony,' which, it is believed, was intended to convey by musical expression the impressions he received during a visit to Cologne. It was first performed on 6 Feb. 1851, almost exactly three years before that sad day when, in a state of utter mental distraction, he sought to end his life by jumping into the Rhine. He was saved by some boatmen, but unmistakable signs of insanity soon appeared, although for a brief period later his mind became wonderfully calm and clear, and with it returned his old love of work. His mental powers were shattered, however, and the last two years of his life were spent in an asylum at Endenich. He was buried at Bonn. A monument over his grave was unveiled on 2 May 1880.

Schumann's works present a rare combination of passion and tenderness. He did much for the development of piano-playing and his numerous songs reveal the grandeur and depth of his unselfish nature. His compositions consist of orchestral works, vocal works with orchestral accompaniment, choruses, a large number of songs, chamber music and also many pieces for the organ and piano. Striking features of Schumann as a composer are his originality and his cautious approach to the more difficult classes of work. At the outset of his career he chose simple forms, building several together for his longer pieces. From this method, however, resulted no unevenness or inharmoniousness, a fact which bears strong witness to the greatness of his creative abilities. In the composition of songs Schumann must be conceded to take rank with such composers as Schubert and Mendelssohn. As one of his biographers writes: "Schubert shows the greatest wealth of melody, Mendelssohn the most perfect roundness of form; but Schumann is by far the most profoundly and intellectually suggestive."

Until Schumann reached his 30th year he wrote almost entirely for the piano, and his method of treating the instrument must be regarded as strictly original. He followed none of the methods of the older composers, although he was evidently familiar with their work. His earlier compositions strike the hearer as the result of sudden impulses and, therefore, contain much that is apparently at variance with the established laws of art, but this in no wise detracts from, but rather adds

to, the freshness and originality of their conception.

His symphonies are generally regarded as the most important contributions of this class since the time of Beethoven, whom he approached quite nearly at times, and whose works occasionally served as his models. His love for sacred music was developed only a few years before his death. In writing to a friend in 1851 he said: «It must always be the artist's highest aim to apply his powers to sacred music. But in youth we are firmly rooted to the earth by all our joys and sorrows; it is only with advancing age that the branches stretch higher, and so I hope that the period of my higher efforts is no longer distant.» Several compositions of this class are recorded, one of the most famous being op. 71, an Advent hymn for solo, chorus and orchestra; op. 93, a motet for men's voices; op. 144, a New Year's hymn for chorus and orchestra; his 'Mass,' op. 147, and a 'Requiem,' op. 148. These, while not counted among his greatest works, nevertheless were grandly conceived. For list of Schumann's works see catalogue of Schuberth & Co., 1860–61, and supplement to 'Musikalisches Wochenblatt' (Leipzig 1875). R. I. GEARE,
National Museum, Washington, D. C.

SCHUMANN-HEINK, Mme. Ernestine, nee **Rössler,** opera and concert singer: b. Lieben, near Prague, Bohemia, 15 June 1861; d. Hollywood, Calif., 17 Nov. 1936. Her father was an Austrian army officer; her mother, an Italian. She was educated at the Ursuline Convent, Prague; sang in the convent choir at 11; studied under Marietta von Leclair at Graz, 1874; appeared as soloist with the Academischer Gesangverein, 1876; later studied with Krebs-Michalesi and Franz Wüllner, Dresden; made operatic debut there, 1878; sang in Berlin, 1887; sang at all performances of the 'Ring' at Bayreuth, 1896–1906 (except 1904); joined Berlin Opera, 1898, with permission to sing in America during the winters; made American debut at Chicago, 7 Nov. 1898; and New York debut with the Metropolitan Opera Co., 9 Jan. 1899, her success being so great she purchased the release of her Berlin contract. First extended American concert tour made, 1903–04; sang in concert and opera in Europe, 1908–09; created role of Clytemnestra in Strauss' 'Elektra' at Dresden. After retiring from the Metropolitan, she devoted most of her time to concert work for many years, giving about 100 recitals annually. Her operatic répertoire included about 150 roles. Late in life she was frequently heard over the radio. She was regarded as the greatest contralto of her time, and was a noble character. She was thrice married. During the World War she had sons fighting in both the German and American armies. One was killed on each side. She became an American citizen in 1905.

SCHURMAN, shoor'man, **Jacob Gould,** American educator and diplomat: b. Freetown, Prince Edward Island, 22 May 1854. He was descended from a Dutch family which, in the 17th century, settled in New Holland, now New York, where his grandfather was born. Educated in the provinces, he received the Dominion Gilchrist Scholarship in 1875 and studied later at London and Edinburgh universities. He was elected to the Hibbert traveling fellowship in 1878 and spent two years at Heidelberg, Berlin and Göttingen, mainly occupied with the study of philosophy. In 1880 he became professor of philosophy and English literature at Acadia College, Nova Scotia, and in 1882 removed to a similar post at Dalhousie College. In 1886 he became professor of philosophy at Cornell University; in 1890 he was made dean of the Sage School of Philosophy there; and from 1892 until he resigned in 1920 he was president of the university. President McKinley appointed him to head the first United States Philippine Commission, and he was joint author of its report (4 vols. 1900). He was Minister to Greece and Montenegro, 1912–13; first vice-president of the New York State Constitutional Convention, 1915; Minister to China, 1921–25; and Ambassador to Germany, 1925–30. He wrote 'Kantian Ethics and the Ethics of Evolution' (1881); 'The Ethical Import of Darwinism' (1888); 'Agnosticism and Religion' (1896); 'A Generation of Cornell' (1898); 'Philippine Affairs—A Retrospect and Outlook' (1902); 'The Balkan Wars' (1912–13); 'Why America is in the War' (1917). He held honorary degrees from various universities. Died, New York City, 12 Aug. 1942.

SCHURZ, shoorts, **Carl,** German-American publicist, editor and author: b. Liblar, near Cologne, Prussia, 2 March 1829; d. New York City, 14 May 1906. He studied at the University of Bonn, in 1848 with others published a revolutionary journal, in 1849 escaped to the Palatinate upon the failure of an insurrection which he promoted at Bonn, took part in the defense of Rastadt and upon its surrender fled to Switzerland. In 1850 he returned to Germany, going thence to Scotland and to Paris, where he was a correspondent for the German press, and, after a year in London, came to the United States (1852), where until 1855 he resided in Philadelphia. Having then removed to Madison, Wis., he identified himself with the Republican party, and by his speeches made himself an important factor in determining the German element of the State against slavery. He participated in the Lincoln-Douglas senatorial canvass in Illinois, entered legal practice at Milwaukee, was a member of the National Republican Convention of 1860 and assisted largely in the framing of its platform. During the ensuing campaign he spoke much in both German and English. He was appointed by Lincoln Minister to Spain, but in December 1861 resigned to enter the army, receiving a commission as brigadier-general of volunteers. He distinguished himself at the second Bull Run (Manassas), was promoted major-general, 14 March 1863, commanded a division at Chancellorsville, held temporary command of the 11th corps at Gettysburg and took part at Chattanooga. After the war he returned to professional practice, in 1865–66 was Washington correspondent of the New York *Tribune,* and was made by President Johnson a special commissioner to report on the workings of the Freedmen's Bureau. In 1868 he was temporary chairman of the convention that nominated Grant, whom he actively supported in campaign. In 1869–75 he was senator from Missouri. He vigorously opposed many of the leading measures of the Grant administration, in 1872 helped to organize the «Liberal» party and presided over the Cincinnati convention which nominated Greeley, but in 1876 supported Hayes, by whom he was made Secretary of the Interior. He introduced competitive examinations for posts

in the civil service, and provided for forest protection on public domains. From the close of the administration to 1884 he was editor of the New York *Evening Post*. His speeches and contributions to periodicals were numerous and able. A statue of him has been erected on Morningside Drive at 116th street, New York City.

SCHUTZSTAFFEL (SS), a body of German troops which grew out of the Adolph Hitler headquarters guard called Sturmabteilung (SA), a group of professional hoodlums and bouncers organized in 1923. The Schutzstaffel, which, literally translated means "protective echelon," was more familiarly known during World War II as the Elite Guard. It began its real expansion in 1929 under the leadership of Heinrich Himmler, who defined its purpose "to find out, to fight, and to destroy all open and secret enemies of the führer, the National Socialist movement, and our racial resurrection."

Himmler's aim was to restrict enlistments to perfect physical specimens of pure Aryan stock traced back for 200 years. These were to have become "the fathers of the new Germany."

In 1933 the Schutzstaffel was divided into three groups, one of which, the SS-Verfugungstruppe (SS-VT), developed into the Waffen-SS. These were the fighting SS: organized into regular army divisions with the finest equipment available, given the most intensive and detailed training, and placed in the line for only specialized assignments. Their arrogance and superior attitude led to ill-feeling with Wehrmacht troops, and their allegiance to Himmler resulted in disunity of command in many sectors.

They fought with ruthless fanaticism and eventually won the fear and hatred of even their own people. Upon acceptance into the Schutzstaffel, a man was tatooed on the under side of the upper arm with the lightning SS insignia. This identified them to Allied troops as war criminals and accounted in part for their reluctance to surrender.

At least five SS divisions were fully trained by the time Poland was invaded in 1939, and by 1942 an estimated 750,000 men had been enlisted by the SS.

SCHUVALOFF, shoo-vä'lŏf, **Peter Andreievitch,** COUNT, Russian diplomat: b. Saint Petersburg, Russia, July 15, 1827; d. there, March 22, 1889. He entered the army, and rose to the rank of general at 30. He was head of a department in the Ministry of the Interior in 1862, governor of the Baltic provinces in 1864–1866, and in the latter year was appointed chief of the secret service. He was sent to London in 1873 as special ambassador and arranged the marriage between the daughter of Alexander II and the duke of Edinburgh. In 1878, he was a representative at the Congress of Berlin. As ambassador to England, he was instrumental in preserving friendly relations between Great Britain and Russia after the Russo-Turkish War of 1877–1878. Prince Gortschakoff was displeased with his concessions and recalled him from London. Thereafter he took no part in public affairs.

SCHUYLER, Eugene, American diplomat: b. Ithaca, N. Y., Feb. 26, 1840; d. Cairo, Egypt, July 18, 1890. He was graduated from Yale in 1859 and from Columbia Law School in 1863. After practicing law, he entered the diplomatic service in 1866, was consul at Moscow and Reval and secretary of legation at Saint Petersburg, 1870–1876. In 1876, he was transferred to Constantinople and that year, after careful investigations, rendered an important report on the Turkish massacres in Bulgaria. In 1878, he was consul at Birmingham; the next year, consul general at Rome; and in 1880, chargé d'affaires and consul general at Bucharest. In 1881, the United States government authorized him to arrange and sign the commercial and consular treaties with Rumania and Serbia, and in the following year he assumed toward those two countries and Greece the post of minister-resident and consul general.

SCHUYLER, Louisa Lee, American social worker, great-granddaughter of Gen. Philip Schuyler and of Alexander Hamilton: b. about 1838; d. Highland Falls, N. Y., Oct. 10, 1926. She was a member of the United States Sanitary Commission in the Civil War and one of the organizers and an officer of the New York State Charities Aid Association, founded in 1873. In 1874, she originated the first American training school for nurses at Bellevue Hospital against the protest of a considerable share of the management, which grudgingly allotted six wards for its practice field. In 1907 she was appointed a trustee of the Russell Sage Foundation. She received in 1915 an honorary LL.D. from Columbia University in recognition of her great public service.

SCHUYLER, Philip John, American soldier: b. Albany, N. Y., Nov. 20, 1733; d. there, Nov. 18, 1804. He was the second son of John Schuyler, owner of a large estate near Albany. He served in the French and Indian War in two campaigns (1755 and 1758), first as captain and afterward as commissary with the rank of major. In 1761, he went to England to settle the colonial claims. Returning in 1763, he successfully engaged in the lumber business at Saratoga. He built the first flax mill in America. In 1764, he acted as a boundary commissioner to determine the line between New York and Massachusetts and later helped settle the New Hampshire boundary. In 1768, he was chosen as Albany's representative in the colonial assembly where he earnestly defended the side of the colonists. In 1775, he was a delegate to the Continental Congress and served on the committee to frame rules and regulations for the Continental Army. He was appointed major general June 19, 1775 and placed in command of the department of northern New York, with headquarters at Albany. He planned to invade Canada and proceeded as far as Lake Champlain, where he left Gen. Richard Montgomery in command of Fort Ticonderoga, while he returned to Albany to raise more troops and forward supplies. Early in 1776, he led an expedition to Johnstown, N. Y., where he captured the military stores of the British. Owing to a clash with Gen. Horatio Gates he offered his resignation (Sept. 14, 1776), which Congress would not accept. In 1777, he was appointed chief of the Pennsylvania militia and in June was again placed in command in northern New York. On July 4, 1777 Ticonderoga was evacuated by Gen.

Arthur St. Clair. Despite a masterful retreat, Schuyler was superseded by Gates on August 4. At his own insistence, General Schuyler was tried by court-martial for alleged neglect of duty in permitting the capture of Fort Ticonderoga. He was acquitted and completely vindicated in 1778. The following year he resigned from the army but remained on the Board of Indian Commissioners. In 1779–1780 he was again a delegate to the Continental Congress and in 1780 he also was chairman of a committee at Washington's headquarters concerned with reorganizing staff departments of the army and unifying forces with the French. He entered the New York State senate in September 1780 and held public office continuously until 1798. Schuyler actively supported the successful campaign of the Federalists to secure New York State ratification of the Constitution in 1788. With Rufus King (q.v.), he represented New York in the first United States senate in 1789–1791 and was re-elected in 1797 to serve until his retirement due to ill health in 1798. He married Catherine Van Rensselaer September 17, 1775 and had eight surviving children. His daughter Elizabeth became the wife of Alexander Hamilton.

Consult B. J. Lossing, *The Life and Times of Philip Schuyler* (1860–1873) and Bayard Tuckerman, *The Life of General Philip Schuyler* (1903).

SCHUYLERVILLE, skī'lēr-vĭl, N. Y., village in Saratoga County; altitude 139 feet; about 32 miles north of Albany; on the Saratoga and Schuylerville Railroad. It is a tourist resort, with many historical associations and monuments in and near it. Its original name, Saratoga, is retained in the name of Saratoga Springs, famous resort ten miles to the west. The first settlement on the site, made in 1689, was burned in an Indian raid, in 1745. The restored village was incorporated under its modern name in 1831, and was named in honor of Gen. Philip Schuyler (q.v.), who planned the campaign against Burgoyne. Located on the direct line of traffic from the Hudson to Lake Champlain and Canada, this region was at the center of a field of vital action in the early years of the revolution. The Battle of Saratoga is commemorated by a lofty monument housing collections of revolutionary relics. A niche on each face of its square base preserves the memory of an American of the time: those of Generals Schuyler and Gates and Colonel Daniel Morgan (q.v.) with statues, and that of Benedict Arnold with an empty space. The battlefield site, about eight miles south of the village, was set apart in 1948 as Saratoga National Historical Park. Pop. (1950) 1,314.

SCHUYLKILL, skōōl'kĭl (from the Dutch word *schuilkil* meaning "hidden channel"), a river in Pennsylvania which has its rise in Schuylkill County, flows southeast and enters the Delaware River at Philadelphia. The total length is about 131 miles. Philadelphia obtains a large part of its water supply from the Schuylkill. The industrial cities of Pottsville, Reading, Pottstown, and Norristown developed along its banks.

SCHUYLKILL HAVEN, Pa., borough in Schuylkill County; altitude 526 feet; on the Schuylkill River; 5 miles south of Pottsville; on the Pennsylvania, Lehigh, and Reading railroads. Manufactures shoes and textiles. Pop. (1940) 6,518; (1950) 6,597.

SCHWAB (shwŏb), **Charles Michael,** American industrialist: b. Williamsburg, Pa., Feb. 18, 1862; d. New York City, Sept. 18, 1939. His father moved to Loretto, Pa., in 1867, and there Charles Schwab grew up, attended the village school and later St. Francis College. There also he first drove a mail coach to Cresson, Pa., then worked in a grocery store in Braddock, Pa., before he started out as a stake driver in the engineering corps of the Edgar Thompson Steel Works, part of the growing properties of the Carnegie Brothers, later to become part of the Carnegie Steel Company, Ltd. In 1881 he was made chief engineer and assistant manager of the plan. In 1887 he was made superintendent of the Homestead Steel Works, another Carnegie property, and in 1889 he returned to the Thompson Works as general superintendent. In 1892 he was made general superintendent also of the Homestead Works, and in 1897 was made president of the Carnegie Company. Four years later, when the Carnegie properties were combined with the Morgan interests to form the United States Steel Corporation, he was made president of the new company. In 1903 he resigned and shortly after became head of the Bethlehem Steel Corporation which he developed into one of the great industrial concerns of the world. In 1913 he became chairman of the board. In 1918 he served as director general of shipbuilding, United States Shipping Board, Emergency Fleet Corporation. After the armistice he returned to the directorship of Bethlehem Steel, a position which he held until his death in 1939. He also was a director of the Metropolitan Life Insurance Company and president of the American Iron and Steel Institute. Mrs. Schwab, the former Miss Emma Eurana Dinkey of Loretto, died in January 1939.

SCHWAB (shväp), **Gustav,** German writer: b. June 19, 1792 at Stuttgart; d. there, Nov. 4, 1850. With Uhland and Werner he was a leading disciple of the Swabian school of poetry. His light poetry, romances and life of Schiller (1840) are memorable. Aside from anthologies of German prose and lyric poetry, his published works include a book of verse entitled *Der Bodensee* (1827); *Die Schönsten Sagen des Klassischen Altertums* (3 vols. 1838–1840); and *Die Deutsche Volksbucher,* 3 vols. (1836 ff.).

SCHWANN, shvän, **Theodor,** German physiologist: b. Neuss, Dec. 7, 1810; d. Cologne, Jan. 11, 1882. He studied at Cologne, Bonn, and Würzburg and graduated in medicine at Berlin in 1834. There he became the assistant of Johannes Müller (q.v.) and in this capacity discovered pepsin (q.v.) about 1836. He also demonstrated important researches on putrefaction and fermentation which influenced the work of Pasteur and Lister. Muscular contraction and nerve fibers were two of his other fields. In 1838 Schwann became professor of anatomy at Louvain, and in 1848 at Liége. His most important work was the origin of the cell theory later developed by Rudolf Virchow (q.v.). In 1839 he published his celebrated *Microscopic Investigations on the Accordance in the Structure and Growth of Plants and Animals,* translated into English in 1847. Here he points out that both animals and plants are made up of elementary units, the cells. See also Cell.

SCHWANTHALER, shvän'tä-lēr, **Ludwig**

von, German sculptor: b. Munich, Aug. 26, 1802; d. there, Nov. 14, 1848. He studied in Munich and in Italy. After returning to Munich from his first trip to Rome in 1826 he set up a studio, and began executing statues and bas-reliefs for royal palaces and museums built by King Ludwig I of Bavaria. Early in his career he did decorative work for the gallery facing the glyptotheca, and 25 marbles commemorating painters for the Old Pinakothek. From 1832 on he received numerous commissions and in 1835 he was appointed professor in the Munich Art Academy. He executed 12 gilded, bronze figures 10 feet high of Bavarian princes for the throne room in the palace at Munich. His work for the Hall of Fame (Ruhmeshalle) included the colossal, 60-foot figure of *Bavaria* and ninety-two metopes. For the Walhalla in Regensburg he executed pediment groups. Notable among his portrait statues are *Shakespeare* in the Munich theater, *Goethe* in Frankfurt am Main, *Mozart in Salzburg,* and the *Emperor Rudolf* in the cathedral at Spires. Starting out as a neo-classicist, he later developed into a romanticist. The Schwanthaler Museum in Munich contains his models and studies which he willed to the Munich Art Academy.

SCHWARTZE, Teresa, Dutch painter: b. Amsterdam, Dec. 20, 1852; d. there, Dec. 23, 1918. She studied first under her father, Johan Georg Schwartze (1814–1874) and then in Munich and Paris. She excelled in portrait painting, her work being memorable for its fine character drawing, strong handling, and rich coloring. Two of her best pictures, a portrait of Piet J. Joubert and a genre painting entitled *Three Inmates of the Orphanage at Amsterdam,* are in the Ryks Museum in Amsterdam. Also notable is *The Orphan* in the Boyman Museum, Rotterdam.

SCHWARZ, shvärts, **Karl,** German Protestant theologian: b. on Isle of Rügen in the Baltic, Nov. 19, 1812; d. March 25, 1885. He studied theology and philosophy at Halle, Bonn, and Berlin. His advanced political opinions interrupted the progress of his career several times. In 1837 he spent six months in prison and in 1845 he was suspended from lecturing at Halle. However, he later advanced with such honors as the appointments of professor extraordinarius at Halle in 1849 and chief court preacher in 1858. Schwarz was one of the founders and leaders of the German Protestant Union and a champion of liberal theology. His writings include *Das Wesen der Religion* (1847) in which may be observed the influence of Hegel and Friedrich Schleiermacher, and an important source for the history of theology in Germany entitled *Zur Geschichte der neuesten Theologie* (1856, 4th ed., 1869).

SCHWARZENBERG, von, fŏn shvär'tsĕnbĕrĸ, princely Austrian family including:

Prince Felix, Statesman, b. Krumlov, Bohemia, Oct. 2, 1800; d. Vienna, April 5, 1852. After aiding in the suppression of popular uprisings in Italy in 1848, he became prime minister of a reactionary Austrian government, 1848–1852. He forced the abdication of Ferdinand and put Francis Joseph on the throne as emperor. Shortly after, in 1849, he dissolved the Kremsier Reichstag and the same year suppressed popular insurgents in Hungary. In 1850 Schwarzenberg restored the old federal diet, a diplomatic triumph for Austria at the expense of Prussia. He also caused Francis Joseph to suspend what remained of the constitution in 1851.

Prince Karl Philipp, Austrian prince and soldier: b. Vienna, April 15, 1771; d. Leipzig, Germany, Oct. 15, 1820. He began his military career in the imperial cavalry in 1788, and later served with distinction in the battles of Hohenlinden (1800), Ulm (1805), and Wagram (1809). After the Peace of Vienna he was Austrian ambassador to Paris where he made negotiations for the marriage of Napoleon to the archduchess Maria Louisa in 1810. At Napoleon's request he commanded the Austrian contingent in Russia in 1812, and was created a field marshal. However, when Austria joined Russia and Prussia, Prince Schwarzenberg commanded the allied forces, gained the battle of Leipzig in 1813 and led the victorious armies into Paris.

Consult Prokesch-Osten, *Denkwürdigkeiten aus dem Leben des Feldmarschall's Fürsten Schwarzenberg* (1823) and Berger, *Das Fürstenhaus Schwartzenberg* (1866).

SCHWATKA, shwŏt'kà, **Frederick,** American Arctic explorer: b. Galena, Ill., Sept. 29, 1849; d. Portland, Oreg., Nov. 2, 1892. He was graduated from West Point in 1871, and, while serving as a second lieutenant at army posts in the United States, he studied both medicine and law. From 1878–1880 he and William Henry Gilder, of the New York *Herald,* headed an expedition to King William Island, Northwest Territories, in search of records and remains of Sir John Franklin's Arctic exploring party. During their search they made a sledge journey of 3,251 miles, the longest then on record. They succeeded in locating many graves and some wreckage of the lost expedition and also established the fact that Franklin's records were undoubtedly lost. Schwatka next explored the course of the Yukon River in Alaska, 1883–1884. The following year he resigned his army commission to devote himself to exploring, writing, and lecturing. He headed the New York *Times'* Alaskan expedition of 1886 and later went to Chihuahua in northern Mexico where he investigated the Tarahumarí Indians. He was the author of *Along Alaska's Great River* (1885); *Nimrod in the North* (1885); *The Children of the Cold* (1886); and *In the Land of Cave and Cliff Dweller* (1893).

Consult W. H. Gilder, *Schwatka's Search* (1881).

SCHWEINFURT, shvīn'fo͝ort, German city in Lower Franconia, Bavaria, on the Main, 66 miles east of Frankfurt am Main. First mentioned in 791, it was made an imperial city in 1282. The city has a Gothic church with a tower and a 16th century Renaissance town hall. Aside from being a river port and agricultural trading center, it manufactures ball bearings, chemical products, dyes and soap. During World War II it was heavily bombed by Allied planes before being taken by American forces on April 12, 1945. Pop. (1939) 49,560.

SCHWEINFURTH, shvīn'fo͝ort, **Georg August,** German traveler in Africa: b. Riga, Dec. 29, 1836; d. Berlin, Sept. 20, 1925. He was educated at Heidelberg, Munich, and Berlin. From 1863–1866 he circled the Red Sea, is said to have traversed the region between the Red Sea and the Nile, from thence journeyed to

Khartoum, and finally returned to Europe. In 1869 he started on an expedition through the interior of East Africa, exploring the countries inhabited by the Bongo, Dinka, Diur (Dyoor), Niam-Niam, and Mangbettu (Monbuttu) peoples. His discovery of the Akka Dwarf proved the existence of pygmies in Africa. In 1870 he discovered the Uele (Welle) River in the Belgian Congo. His next expedition (1873–1874) took him into the Libyan Desert with Gerhard Rohlfs. The following year he settled in Cairo to devote himself to his African studies, and at intervals, from 1876 to 1888, he explored the Arabian Desert. Among his published works are *The Heart of Africa* (Eng. ed., 1873) and *Artes Africanae; Illustrations and Descriptions of Productions of the Industrial Arts of Central African Tribes* (1875).

SCHWEINITZ, shwī'nĭts, **George Edmund de**, American ophthalmologist: b. Philadelphia, Pa., Oct. 26, 1858; d. there, Aug. 22, 1938. After graduation from Moravian College in 1876 he took his M.D. at the University of Pennsylvania in 1881, and was professor of ophthalmology at that university from 1902 until 1924; in 1922–1923 he was president of the American Medical Association. Schweinitz is known for his work on the prevention of blindness. Among his books is *Diseases of the Eye* (1892, 10th ed. 1924).

SCHWEINITZ, Lewis David von (or de), American Moravian clergyman and botanist: b. Bethlehem, Pa., Feb. 13, 1780; d. there, Feb. 8, 1834. In 1798 he went to Germany where he studied theology and entered the Moravian ministry. He returned to the United States in 1812 as general agent of the Moravian Church at Salem, N. C., and in 1821 he was appointed administrator of the church's northern province with headquarters at Bethlehem, Pa. An enthusiastic botanist, he added about 1,200 new species to the catalogue of American flora. His valuable collection of plants he left to the Philadelphia Academy of Natural Sciences. He published, among other studies, *The Fungi of North Carolina* (1818) and *A Synopsis of North American Fungi* (1831). His son, Edmund Alexander de Schweinitz (1825–1887), was a Moravian bishop and historian; a grandson, Emil Alexander de Schweinitz (1866–1904), was a noted biochemist.

SCHWEITZER, shvī'tsĕr, **Albert**, Alsatian medical missionary, philosopher, Protestant theologian, and musician: b. Kaysersberg, Alsace, Jan. 14, 1875. His father, a Lutheran minister, moved the family to the Alsatian village of Günsbach where Albert attended the local school. After completing his secondary schooling in Münster and the gymnasium at Mulhouse, he went to Paris in the summer of 1893 to take lessons from the eminent organist Charles Marie Widor, with whom he later edited (1912–1914) J. S. Bach's organ music. From the autumn of 1893 to 1899 Schweitzer studied theology and philosophy at the universities of Strasbourg, Paris (Sorbonne), and Berlin. He then became a preacher in the Church of St. Nicholas, Strasbourg, while working for his licentiate in theology which he received in 1900. In 1903 he was appointed principal of the university's theological college, and in 1905 he published his authoritative biography of *Johann Sebastian Bach* in French (Eng. ed., 1911), which was soon followed by *The Quest of the Historical Jesus* (1906, Eng. trans. 1910), the book which first brought him international regard.

At the age of 30, he decided to devote himself to "the direct service of humanity" and accordingly he took up the study of medicine at the University of Strasbourg in 1905. In 1911 he received his medical degree and two years later sailed for Gabon, French Equatorial Africa, to set up a native hospital at Lambaréné. His wife, the former Hélène Bresslau, whom he married in 1912, accompanied him as a nurse. Before they were interned as enemy aliens in 1914, the Schweitzers treated some 2,000 native patients during their first nine months in Africa. During his internment Schweitzer worked on his book, *The Mysticism of Paul the Apostle,* published in 1930 (Eng. ed., 1931; rev. ed., 1953). The next few years he toured Europe giving concerts and lectures to support his humanitarian work at Lambaréné. In 1923 the first two volumes of his philosophical work were brought out: *The Decay and Restoration of Civilization* and *Civilization and Ethics;* later published in one volume in a revised American edition as *Philosophy of Civilization* (New York 1949). This work, starting with a theoretical pessimism in attempts to find a scientific explanation of the world, develops his own ethical optimism or "reference of life." After 1924 Schweitzer divided his time between work at Lambaréné, building up his hospital units and native practice, and intermittent European lecture tours.

In 1928 he received the Goethe Prize of ten thousand marks from the city of Frankfurt, Germany. The 1952 Nobel Peace Prize was awarded to him on Oct. 30, 1953.

Other books of his, most of them translated into English, include *The Religious Philosophy of Kant* (1899); *Psychiatric Study of Jesus* (1913; Eng. trans. 1948); *Paul and His Interpreters* (1911; Eng. ed., 1912); *On the Edge of the Primeval Forest* (1921; Eng. ed., 1922); *Memoirs of Childhood and Youth* (1924); *Out of My Life and Thought* (1931; Eng. trans. 1933; rev. ed. 1949); *Indian Thought and its Development* (1935; Eng. ed., 1936); *From My African Notebook* (1939); *Goethe: Four Studies* (1949); *Animal World: Jungle Insights into Reference for Life* (1950).

Charles Rhind Joy edited in 1947 *Albert Schweitzer: An Anthology* (rev. ed. London 1952), followed by *Wit and Wisdom of Albert Schweitzer* (Boston 1949), and *Music in the Life of Albert Schweitzer* (Boston 1951).

Consult Seaver, George, *Albert Schweitzer: Christian Revolutionary* (New York 1944); Hagedorn, H., *Prophet in the Wilderness* (New York 1947); Kraus, Oskar, *Albert Schweitzer: His Work and His Philosophy* (New York 1947); Seaver, George, *Albert Schweitzer: The Man and His Mind* (New York 1947); Joy, C. R. and Arnold, M., *The Africa of Albert Schweitzer* (Boston 1948); Ratter, M. C., *Albert Schweitzer: Life and Message,* rev. American ed. (Boston 1950); and Mozley, E. N., *Theology of Albert Schweitzer* (New York 1951).

SCHWELLENBACH, shwĕl'ĕn-bäk, **Lewis B(axter)**, American public official: b. Superior, Wis., Sept. 20, 1894; d. Washington, D.C., June 10, 1948. Admitted to the Washington state bar in 1919, he began practice in Seattle where he became partner of a law firm in 1925. In 1935 he was elected to the United States Senate from the State of Washington, and in 1940 he resigned to become United States district judge of the Eastern District of Washington. Judge Schwellenbach succeeded Frances Perkins as secretary of labor in President Harry S. Truman's cabinet in 1945.

SCHWENKFELD, shvĕngk'fĕlt, **Kaspar von,** German Protestant theologian and Silesian nobleman: b. Silesia, 1489; d. Ulm, Dec. 10, 1561. He entered the service of the duke of Liegnitz and was influential in spreading the principles of the Reformation in Silesia. However, he differed from Luther on several points of theology, chiefly on the sacrament of the Eucharist, and was opposed by both Protestants and Catholics. After the publication of a book in 1539, which set forth his distinctive doctrine of the deification of Christ's humanity, he was actively persecuted by the Lutherans. The following year he published an enlarged statement of his views in a book entitled *Grosse Confession.* After Schwenkfeld's death in 1561, a sect called the Schwenkfeldians perpetuated his views, including the rejection of Lutheran sacraments. His followers were subjected to greater or less persecution and finally in 1720, when a commission of Jesuits was sent into Silesia to convert them, many fled to Holland, England, and North America. In 1734 a group emigrated to Philadelphia, Pa., and formed a community known as Schwenkfelders which still exists in Pennsylvania today. They maintain a few small churches which appear to resemble those of the Society of Friends.

SCHWENKFELDIANS. See RELIGIOUS SECTS.

SCHWERIN, shvâ-rēn', Germany, capital of the former state of Mecklenburg, picturesquely situated on the southwest shore of Lake Schwerin, 20 miles south of the Baltic and 129 miles by rail northwest of Berlin. It is a railroad junction and has an airport. In addition to Lake Schwerin, which is 14 miles long and three wide, a number of smaller lakes surround the town. Among other notable structures, it contains a former grand ducal castle, French Renaissance in style, built in 1844–1857 on a small island; a Gothic cathedral which dates for the most part from the 15th century; a library; an arsenal; and a museum. It manufactures lacquered wares, machinery, cloth, tobacco and beer. The town was first mentioned in 1018 and received civic rights in 1166. Pop. (1939) 64,639.

SCHWIND, shvĭnt, **Moritz von,** German painter: b. Vienna, 1804; d. Munich, 1871. Starting out with little formal training in his youth, Schwind went to Munich in 1827 and in 1834 he received a commission to decorate a room in King Ludwig II's new palace, later known as the Tieck room. In 1844 he moved to Frankfurt am Main where he painted the *Singer's Contest in the Wartburg* two years later. He became a professor at the Munich Art Academy in 1847. Among his other works are a series of wall paintings for the Hohen-Schwangau Castle in the Bavarian Tirol, another series for the Wartburg Castle, and three great water color cycles. His illustrations of Goethe and other poets brought him much popularity. Part of his genius lies in his sense of humor and deep sensitivity to beauty. Schwind is considered a master of the German late-romantic school.

SCHWYZ, shvēts, Switzerland, capital of the canton of Schwyz; altitude 1,706 feet; three miles from Brunnen, its port on the Lake of Lucerne. Included among points of interest in this picturesque Swiss town are the 16th century town hall, a handsome 18th century parish church and some interesting old houses. The town is chiefly a tourist center and its inhabitants are German-speaking. Pop. (1930) 8,256.

SCIACCA, shäk'kä, Italy, a seaport town and bishop's see in southwest Sicily, in the province of Agrigento, 30 miles northwest of Agrigento. Walls built about 1550 still surround the town which has two ruined castles, medieval and 18th century palaces, several interesting churches, and a convent. Hot sulfur and ferruginous springs are located nearby. Pop. 22,713.

SCIAENIDAE, sī-ĕn'ĭ-dē, a family of percomorphous, spiny-rayed teleostomous fishes, in which the body is usually slightly compressed and elongated and covered with thin, slightly ctenoid scales. The head is scaly and its superficial bones are remarkable for the extensive development in them of passages for the mucous canals. The fins are well developed and there are not more than two spines. The air bladder is generally a specialized structure; it is by forcing air through this organ that the peculiar grunting and rumbling sounds produced by these fishes are caused. Most of the species are marine and littoral, but a few are fresh-water. Most of them feed upon other fish but some upon crustaceans and mollusks. The family is an extensive one represented by a variety of species with world-wide distribution. They are especially numerous along the sandy shores of warm seas, and many of them are good food and game fish. Weakfish, drumfish, croakers, kingfish and spot belong to this family.

SCIATICA, sī-ăt'ĭ-kạ, a painful neuritis of the sciatic nerve, which is the chief nerve of the back of the thigh and leg. It is characterized by extreme pain, often excruciating and occurring in paroxysms, and increased by any change of temperature and moisture; there is stiffness and generally swelling of the limb at the beginning of the disease, but after repeated attacks the limb seems to shrink, owing to the wasting of the muscles. In some cases the articulation of the hip seems affected, and permanent immobility of the limb takes place. Mild attacks are often called neuralgia of the sciatic. In all cases very careful examination of the pelvis and the bones of the lower part of the spinal column should be made, and all causes for chronic poisoning sought for. It is a very chronic condition. See NEURALGIA; NEURITIS.

SCIDMORE, sĭd'mōr, **Eliza Ruhamah,** American traveler and author: b. Madison, Wis., Oct. 14, 1856; d. Nov. 3, 1928. She joined the National Geographic Society in Washington, D.C. in 1890, and later became its corresponding secretary, associate editor, foreign secretary and member of the board of managers. She traveled widely through Europe and the Orient. Her published works include *Alaska: Its Southern Coast and the Sitkan Archipelago* (1885); *Jinrikisha Days in Japan* (1891); *Java: the Garden of the East* (1897); *China, the Long-Lived Empire* (1900); *Winter India* (1903) and *As The Hague Ordains* (1907).

SCIENCE, History of.—If one defines science as systematized positive knowledge (or what has been taken as such at different ages and in different places), then the history of science is the description and explanation of the development of that knowledge. For example, considering all that we know today in astronomy, how did we obtain that knowledge? It is a very long story which takes us back to prehistoric times when men began to observe the sun, moon, stars, planets—and wondered. Our knowledge of today has been reached only after taking an infinity of steps and false steps.

If one bears in mind that the acquisition and systematization of positive knowledge is the only human activity which is truly cumulative and progressive, one realizes at once the importance of these studies. Should one wish to account for the progress of mankind, one must focus one's explanation upon that activity, and the history of science in this broad sense becomes the keystone of all historical investigations.

Brief Outline.—The definition will be clarified if we illustrate it with an outline of the way the scientific experience of mankind was gradually developed until it reached its present depth and complexity. The reader must be warned, however, that this is not a history of science but simply a general view of it, enough to give him some awareness of the many kinds of investigations which are involved.

Any history must begin with an account of the dawn of science. This is a part of anthropology and prehistory. How did early men invent and fashion their tools? How did they domesticate animals and learn the tricks of husbandry? How did they obtain the rudiments of arithmetic, geometry, astronomy? How did they find the best foods for health and the best drugs for sickness? How did they learn to navigate the waters, to hunt and fish, to lift and transport heavy stones, to dig for ores and smelt them, to make bronze implements and later iron ones? How did they discover the ways of social life in families and tribes, the methods of economy and government? How did they develop a language and means of recording it? Did they achieve a kind of social or historical consciousness, and if so, how did they gratify it? How were artistic and religious needs awakened in them and what did they do to obey them?

These are but a few of the innumerable questions which must be answered in order to understand the level of knowledge which man had attained before the curtain of recorded history rises. The earliest cultures represented by written documents occurred in Egypt, Mesopotamia, India, and China, and an account of these cultures cannot be given without the collaboration of orientalists able to decipher and to interpret those documents. Historians of science must manage to extract from the studies of orientalists all the data pertinent to their own quest and to explain them.

After many vicissitudes and the violent upheaval caused by the discovery and use of iron weapons, a gifted nation, the Greeks, tried to explain the universe and themselves in a deeper way. The earliest of those Greeks were settled along the western coast of Asia Minor, in Sicily and south Italy. We owe them the elements of mathematics, astronomy, mechanics, physics, geography, medicine. Few of their writings have been preserved and what we know is derived from fragments and indirect quotations.

The golden age of Greek science coincided with the golden age of Greek literature and art. Its main center was Athens; the language, Greek; the time, 5th and 4th centuries B.C. The 5th century witnessed great philosophers such as Democritus and Leucippus, who invented the atomic theory, mathematicians like Hippocrates of Chios, astronomers like Philolaus, and physicians like Hippocrates of Cos, "the father of medicine." That golden century was brought to a close by the political murder of Socrates in 399 B.C.

The 4th century was even richer in scientific achievements and it was dominated by two philosophers, two of the greatest personalities of their kind in the whole past: the first half of the century was dominated by Plato, founder of the Academy of Athens; the second half by Aristotle, founder of the Lyceum in the same city. So far-reaching was the influence of these men that to this day every thinking man, every scientist, may be said to be either a Platonist or an Aristotelian.

The political ruin of Greece caused such deep changes all around that scholars are agreed in using a new name to designate the new culture which developed chiefly from the 3d century B.C. on. The center was no longer in Athens but in Alexandria and other Greek cities outside of Europe. The new culture was no longer called Hellenic but Hellenistic. It is immortalized by the deeds of 3d century anatomists like Herophilus and Erasistratus and of mathematicians and astronomers like Euclid, Aristarchus, Archimedes, Eratosthenes and Apollonius, the last three flourishing in the second half of that century, and Hipparchus in the late 2d century B.C. The end of the Hellenistic age merged with the Roman age because Rome had become the political master of the Greek world just before the Christian era began. Roman science was but a reflection of the Greek; a few scientific books were written in Latin, however, by Lucretius, and Cicero, in the 1st century B.C., and in the succeeding 1st century A.D. by Celsus, Pliny, and Frontinus. Yet, until the 7th century, all the outstanding names are Greek, the two greatest of all being the 2d century astronomer and geographer Ptolemy and the physician Galen—two giants dominating the golden age of the Roman Empire with Greek writings. Later appear more mathematicians and astronomers like Diophantus and Pappus (3d century), Theon of Alexandria in the 4th, and in the 5th his daughter Hypatia, and Proclus; philosophers like Philoponus and Simplicius (6th century); physicians like Oribasius (4th century), Aetios and Alexander of Tralles in the 6th, and Paulus Aegineta in the 7th century. This has brought us to the time of the Moslem conquest of a great part of the Mediterranean world.

It is impossible to describe here even in briefest manner all the vicissitudes of medieval history. From the 9th century to the 11th, all of Greek knowledge was translated into Arabic and the best new scientific books were written in Arabic. After the 11th century, the whole was gradually retranslated into Latin, and to a smaller extent into Hebrew. The greatest physician of the early Middle Ages was the 11th century ibn-Sina (Avicenna) and the most original scientist was his contemporary al-Biruni. The leading mathematicians and astronomers of that period (9th to 11th century) were all writing in Arabic—al-Khwarizmi, al-Farghani, and al-Battani in the 9th century, Abul-Wefa in the 10th, Omar Khay-

yám and al Zarqali in the 11th—as were the leading philosophers, the 9th century al-Kindi, al-Farabi (10th), and ibn-Sina and al-Ghazzali, both 11th century. Arabic culture was international, extending from the far west (Spain and Morocco) to India; it was interracial and interreligious, for it included not only Moslems but also Jews and Christians. The common features were the Arabic language and the Islamic culture it served to express.

Later medieval thought was dominated by three giants, the Moslem ibn-Rushd (Averroes), the Jew Maimonides (both 12th century), and the 13th century Christian, St. Thomas Aquinas.

The greatest events of the 15th century were the invention of typography about the middle of it and the geographical discoveries initiated by Henry the Navigator and reaching a climax at the end of the century with Columbus and others. These geographical discoveries continued during the 16th century and increased immeasurably human experience in many directions.

The discovery of printing did not mean simply a far greater diffusion of ideas than had been possible before, but also the production of *standard* texts and a little later *standard* illustrations. For the first time the progress of knowledge could be registered forever as soon as it was made, standardized and transmitted to every corner of the civilized world. Until that period East and West had worked together, but the Moslem East, increasingly inhibited by religious obscurantism, rejected printing and ceased to cooperate with the Western world.

The discovery of printing was so pregnant that it is well to consider it the beginning of a new period, the so-called Renaissance, almost exclusively Western (as far as science is concerned). If we define the Renaissance as the period 1450 to 1600, we find that one of its main characteristics was the recovery of the texts of the Greek classics, most of which had been known only through Latin translations of Arabic translations. In other respects the Renaissance was essentially the continuation of the Middle Ages. There were a few giants like Leonardo da Vinci, Nicolaus Copernicus and Andreas Vesalius, Vannoccio Biringuccio and Rodolphus Agricola, Ambroise Paré and Pierre Belon, Konrad von Gesner, Tycho Brahe, William Gilbert and Simon Stevin, and rebels like Philippus Aureolus Paracelsus and Bernard Palissy, but modern science cannot be said to begin in earnest until the 17th century with such men as Francis Bacon, Galileo Galilei, Johannes Kepler, and René Descartes.

During the Renaissance printing shops had become very numerous and the number of printed books had increased immeasurably. The steady accumulation of knowledge was guaranteed. Another powerful means of controlling and recording the progress of science was the establishment of academies. The first academies of science date from the 17th century, the Accademia dei Lincei in Rome (1603–1630), the Accademia del Cimento in Florence (1657–1667), the Royal Society in London (1662), the Academie des Sciences in Paris (1666). The books and journals sponsored by those academies and a few other journals such as the *Journal des savants* of Paris (1665) and the *Acta eruditorum* of Leipzig (1682) guided the activities of men of science wherever they were working.

Almost all the leading scientists were fellows of at least one of these academies, and it would be possible to describe the development of science in innumerable directions on the basis of the academic publications. The main monuments of modern science, however, are the great treatises such as the *Principia mathematica* of Sir Isaac Newton (1687) (see PRINCIPIA), the *Traité de la lumière* of Christian Huygens (1690) and a great many others, too many to be listed.

In the 17th and 18th centuries the number of distinguished men of science is so great that an enumeration of them would be impossible. It is more interesting to point out that they were distributed all over Europe. It became clearer than ever that scientific activities are international; the history of science in any one country, however great, is very incomplete, because some of the essential work was done in other countries. Even such a small country as Switzerland produced its full share of scientific heroes: Paracelsus, Gesner, the Bernoullis, Albrecht von Haller, Leonhard Euler, Lambert, Steiner, and others. Young America started making her own gifts with Benjamin Franklin, John Winthrop, Benjamin Thompson (Count Rumford).

During the 19th century, science developed so fast and in so many directions, with almost incredible luxuriance, and yet with so much steadiness that even the best observers were deceived and became a little too optimistic. They believed that science was approaching a stage of perfection. Further progress would simply consist in obtaining an infinity of new data to complete the schemes of the naturalists, or in making physical measurements with greater precision and expressing results with more decimals. That peaceful and optimistic climate was upset toward the end of the century, when there began a series of inventions which changed radically the material conditions of life and caused the 20th century to be so completely different from the preceding ones that the whole past tends to be unified in our remembrance. Many people seem to believe that an entirely new world began in the 20th century, and they are not quite wrong.

Many of these fundamental inventions were not fully developed until the end of the 19th century, but then their growth was so rapid and their diffusion so intense that they have become essential parts of 20th century environment: dynamos, electric motors, telegraphs and telephones, internal combustion engines, phonographs, aviation, cinema, wireless, radio, television, methods of refrigeration, plastics (each of these words could easily be amplified into many volumes). The purely scientific discoveries have been equally revolutionary; they have upset many sciences as deeply as inventions have upset the ways of life. It will suffice to refer to the discovery of X-rays (Wilhelm Konrad Roentgen, 1895), radioactivity (Antoine Henri Becquerel, 1896), and psychoanalysis (Sigmund Freud, 1900 and after), to the rediscovery of Mendelism (1900), to the discovery of the theory of quanta (Max Karl Ernst Planck, 1901), theory of mutations (Hugo De Vries, 1901–1903), radium (Pierre and Marie Curie, 1903), special and general theories of relativity (Albert Einstein, 1905, 1916), and disintegration of the atom (Lord Ernest Rutherford, 1919).

History of Science and Science.—Men of science and technicians want to know the latest results; they consider previous ones as obsolete and disregard them. The historian of science, however, is interested not only in the newest

results but in the whole evolution which has led to them and made them possible. The latest results are like the new fruits of a tree; the fruits serve our immediate needs, yet without the tree the fruits could not come into being. The historian of science wants to know the tree of knowledge with all its roots and branches; he appreciates the fruits of today but not more so than those of the past and the future.

History of Science and History.—Since the 18th century at least, that is, since the time of Giovanni Battista Vico, Montesquieu, and Voltaire, the concept of history has become more and more comprehensive. At first, historians were concerned mainly with political and military history; they learned gradually to attach more attention to arts and letters, religion, and economics. Thus the old political history was transformed into something much broader which might be called the history of culture.

The historical field was extended also in a geographical way. Early historians (like the Jewish ones) were concerned only with the history of their own people; under Greek and Roman influence the geographical field was increased; but a great many centuries were to elapse before historians obtained a sufficient knowledge of all the nations (East and West) and included all of them in their conception of mankind or the scope of their own studies.

It was only in relatively recent times that the importance and centrality of the history of science was realized, and even today the great majority of historians do not realize it fully. There were a few pioneers beginning with the end of the 17th century (not to go back any further). Witness such men as the Swiss, Daniel LeClerc (1652–1722) and Albrecht von Haller (1708–1777); the Germans, J. C. Barkhausen (1666–1723), J. C. Heilbronner (1706–c.1747), Johann Beckmann (1739–1811), A. F. Hecker (1795–1850), Abraham Gotthelf Kästner (1719–1800), Johann Friedrich Gmelin (1748–1804); the English, John Freind (1675–1728), Joseph Priestley (1733–1804), Adam Smith (1723–1790); the Swedish, Olaf Celsius (1670–1756); the French, Jean Etienne Montucla (1725–1799) and Jean Sylvain Bailly (1736–1793).

But the first man to introduce this theme in a broader context and to increase its circulation was the French philosopher, Auguste Comte, who developed it in his *Cours de philosophie positive* (1830–1842). His views were discussed by another French philosopher, Antoine Augustin Cournot in 1861, but the real inheritor of Comte's thought and the first great teacher of the history of science was Paul Tannery (1843–1904). During the 20th century his example has been followed by many scholars in the leading countries. The history of science has become a full fledged discipline; yet the number of men who can devote their whole time to it is still very small.

History of Science and Philosophy.—One would expect philosophers to be specially interested in the history of science, because the philosophical implications of scientific work are not clear until one considers science in its growth. In order to understand a function, it does not suffice to consider only the last points in the curve which represents it; one must take into account the whole curve. On the other hand, the historian of science cannot accomplish his task satisfactorily unless he understands the philosophical implications of science. Many men of science were primarily inventors and technicians, avoiding philosophy; yet none grew up in a philosophical vacuum. Every scientist is influenced by the religious and philosophical conceptions of his time, whether he is aware of it or not.

Methods of Study.—The methods which the historian of science uses are necessarily the same as those used by other historians, but as they must be applied to scientific facts and theories, the historians of science must receive a scientific preparation as well as a purely historical one. It is impossible to understand and to appreciate scientific documents without adequate scientific knowledge. All the difficulties of the history of science stem from the necessity of a double education. Much bad work has been done by historians who did not know science and also by men of science who had no idea of historical methods, and did not even realize that such methods existed.

The main point is that knowledge of any kind is worthless unless it be as accurate as conditions permit. It is here that the conflict of methods appears. A physicist fully aware of all the difficulties of physical measurements may be trusted to do his best to overcome these difficulties; the same man is not aware of historical difficulties and of the need of historical precision.

The historian like the scientist must try to be as accurate as possible, yet must remember that the same degree of precision is not required in every case. For example, when the length of an object is mentioned, the unit varies with the needs; it may be expressed in microns, millimeters, yards, or miles; in the same way, it may be necessary to give the time and date of an event very exactly, say 9 A.M., March 21, 1591 (Gregorian); in other cases, it may suffice to say March 1591, or 1591, or "toward the end of the 16th century." All those expressions are accurate, though their degrees of accuracy vary considerably. To use a higher degree of precision than the circumstances warrant is a form of pedantry. On the other hand, when the historian is investigating any subject he should note the dates and other facts with as much precision as possible; it will be easy enough to diminish the precision in his account if needed, while the reverse procedure is impossible.

Historical methods are on the whole less tangible and more delicate than physical methods, and therefore more difficult to set forth. This is due to the fact that the subject matter of history is human and therefore capricious, even when we are dealing with the development of science. The reactions of a man of science are infinitely more complex than those of the objects he is studying. The methods required to investigate ancient, medieval, or oriental science are, of course, more complex than those needed to explain modern events. In the case of contemporary events, described in our own language, it is hardly necessary to study the background, which we know well enough, or to consider linguistic difficulties. On the other hand, when one tries to appreciate the trigonometrical facts included in Arabic books written in Baghdad in the 9th century, one must be able to evoke the culture of that place and period, understand the Arabic language and Islamic religion, and so forth. That kind of work is not simply historical but philological. The basis of it is always what the philologists call "the establishment of the text." That is (in this case), one must determine as exactly as possible what was written by al-Khwarizmi, by Habash

al-Hasib, by al-Battani; one must establish the text of their very words (either as written by themselves or quoted by others), and it is only after that has been done that their trigonometry ideas can be safely investigated. To assume that al-Battani may have written this or that is worthless and perverse.

The establishment of a text implies a very special and complex training. Philological and historical methods can be learned only through personal experience in their use, and that process of learning is never completed.

Teaching of the History of Science.—As the history of science is a new discipline, the teaching of it is very recent. The first professorship was established at the Collège de France in 1892, but the appointment of unqualified professors defeated the grand aim. Today, over 60 years later, in the writer's opinion university administrators have yet to appreciate (1) the importance of such studies; (2) the need of entrusting them to competent scholars equipped with the necessary training (scientific, historical, philosophical); (3) that such work, being difficult and still in the experimental stage, must be a full time occupation. Too often that teaching has been entrusted, as a kind of side job, to men who, however eminent in other science fields, were not qualified to teach the history of science.

The teaching of the history of science is organized fairly well, though in different ways, in various European and Asiatic universities, as London, Paris, Frankfurt-am-Main, Moscow, and Ankara, and in a few American universities as Harvard, Wisconsin, Cornell, Yale, Johns Hopkins, and Brown. It is possible in those universities to continue these studies up to the degree of Ph.D. Professional historians of science are still exceedingly rare.

History of Science vs. History of Particular Sciences.—It should be noted that the history of science as defined by Comte, Tannery, and the author of this article is essentially different from the history of particular sciences or of particular techniques. To consider technology first, the explanation of its development implies a large amount of economic or sociologic research. Inventions are made to answer definite needs, and each new invention of any importance creates new needs and causes an endless chain of other inventions. For example, the discovery of the first steam engine opened up an enormous branch of technology. Not only were those engines and their accessories gradually improved but their availability suggested new technical departures, such as railways, steamships, and an infinity of other machines. The historian of any branch of technology must be familiar with patent literature and with all kinds of industrial and commercial ramifications, even with legal problems with which the historian of science would hardly concern himself.

On the other hand, the historian of science must try to take into account every branch of science, and investigate their interrelationships which are frequent and complex. Indeed, his main purpose is to explain the development of the whole tree of science, a tree which never ceases to grow in its roots, trunk, and innumerable branches and twigs. He must explain how the progress of one science affected the progress of other branches. For example, the development of microscopes and telescopes implied the solution of physical and chemical problems and other technical difficulties; better microscopes influenced the progress of natural sciences, better telescopes accelerated astronomical progress and enabled us to conceive a universe (or universes) immeasurably larger than the universe of our ancestors.

As the historian of science is writing for scientists and learned men of every kind, he can never assume that the scientific knowledge of his readers is sufficient to understand the intricacies of any problem, and therefore his account should never be too technical. The historian of chemistry expects his readers to know chemical technicalities, but the historian of science cannot entertain the same expectations, for the majority of his readers are not chemists but physicians or physicists, naturalists, astronomers or mathematicians, philosophers or sociologists.

A general treatise on the history of science is thus less technical than one on medical or geological history, but what it loses on that side, it regains on another, because it is far broader. The historian of chemistry is more of a technician, the historian of science is more of a humanist; he is in the fullest sense the historian of mankind.

Diversity of Points of View.—The history of science being a field of endless complexity and incredible size, it would be very foolish to say "This is the way to study it or to teach it, and there is no other." There are many ways, many points of view, each of which is acceptable and useful, none of which is exclusive of the others. Some of the points of view have already been indicated. There is the point of view of the historian who wishes to understand as fully as possible the culture of a nation or of a period; the point of view of a professional man of science who would explore the origin and development of his own knowledge; the point of view of a man of letters who would include science in his survey, either because great men of science are, might, or should be distinguished authors, or because no writer can help having some kind of scientific background; the point of view of the philosopher whose main concern is to show the complex relationship between science and philosophy (how much either influenced the other). There are at least three other points of view also, the logical, psychological and sociological, which deserve to be examined more carefully.

Logical Point of View.—Logicians may be tempted to unravel the logical concatenation of scientific facts and to give a logical interpretation of discoveries. They are bound to be surprised by the results of their inquiries, for the chronological order of discoveries is often very different from the logical one. In science as in art "the wind bloweth where it listeth." What some people call the logic of science is largely casual and retrospective; it is nevertheless useful to bring it out. Discoveries are not always made in logical order, but it is worthwhile and helpful to explain them in that order.

The methods of teaching, which are logical enough, are almost the reverse of the methods of discovery. The teachers of a vast subject, say inorganic chemistry or theoretical mechanics, must put the fundamental notions first in spite of the fact that these notions may have been the very last to be discovered. The teachers are not concerned with the historical order; their main purpose is to explain science as simply and clearly as possible.

Psychological Point of View.—Another set of historians is interested in the individual aspects of scientific work, and ask themselves questions like the following: How did it happen that John Doe made such or such a discovery? Is it to be explained in rational or emotional terms? How does he compare with other scientists as a man, or with other men? How was his temper affected by work, rest or play, by success or failure? How was he influenced by his social environment, and how did he influence it? How did he express and reveal himself, or fail to reveal himself? What was the quality of his spirit? His love of truth, his love of beauty, his love of justice, his religion, to what extent were they developed? Or was he indifferent to the world around him, blind to everything except the narrow field of his research? Not only the psychologist but the humanist tries to answer such questions, and innumerable others.

Social Point of View.—Instead of considering men of science individually and trying to find the individual roots of their activities, one may consider them as members of a social group and investigate the social pressures to which they may have been submitted. According to the official Soviet philosophy, "dialectical materialism" (or "diamat" as it is called in eastern Europe), science is explained primarily, if not exclusively, in social and economic terms. There is a core of truth in such explanations, for science does not develop in a social vacuum and men of science are citizens, whom the state or their employers can use and abuse in many ways. Every man of science needs a modicum of food and other comforts in order to do his work; if called to arms and killed in battle, his activities come to an end; if he is a physicist or astronomer, his opportunities will depend upon the laboratory or observatory to which he has been admitted and his freedom will be limited by the good or bad will of administrators or fellow workers. Yet nobody can completely control his spirit; he may be helped or inhibited, but his scientific ideas are not determined by social factors. Honest men of science have often continued activities detrimental to their material interests. Historians of science should describe such conflicts as carefully as possible, thereby helping us to understand various forms of society and the psychology of exceptional men.

A vast literature devoted to the problems of the impact of society on science and of science on society may be classified under the general heading "Science and Society." A number of books *ad hoc* are listed in the present writer's *Horus* (pp. 94-97), but that list is incomplete and more books appear every day. Sociologists are tempted to restrict their interest in the history of science to these problems and their endless implications.

Theoretical and Practical Uses of the History of Science.—There are obviously many theoretical motives for studying the history of science. A man of science would study that history in order to throw light upon his own task and to increase his enjoyment of it; a philosopher, in order to relate science to philosophy and account for some variations of the latter; a psychologist, to explore the peculiarities and possibilities of the human mind; a sociologist, better to understand the many relationships between scientists and the social groups to which they belong.

The people who study a subject for theoretical reasons are probably exceptional; most students submit themselves to definite training for practical reasons. They wish to qualify themselves for a trade or profession. Looking at it from their angle, the study of the history of science will complete the training of scientific teachers (to teach well one needs a kind of perspective which can be obtained only by historical inquiries); it will improve the qualifications of students for many parascientific positions, such as those of librarians, editors, curators of museums, administrators, and other men having to deal directly or indirectly with scientific pursuits.

Bibliography.—There is no elaborate textbook covering the whole history of science from its prehistoric beginnings up to now. On the other hand, there are innumerable books dealing more or less completely with one branch of science, with one period, with one kind of people, or with one country. The best guide in that labyrinth is provided by Sarton, George, *Horus. A Guide to the History of Science* (Waltham, Mass., 1952).

A general account of the history of science as much as it can be put in one volume may be found in Singer, Charles, *Short History of Science to the Nineteenth Century,* to mid-19th century (Oxford 1941); Dampier, Sir William C., *History of Science,* 4th ed. (Cambridge, Eng., 1949).

Much more elaborate accounts are Thorndike, Lynn, *History of Magic and Experimental Science,* from the 1st to the 16th century, 6 vols. (New York 1923–41); Sarton, George. *Introduction to the History of Science,* from Homer to end of the 14th century, 3 vols. in 5 (Baltimore 1927–48); Sarton, George, *History of Science,* from prehistoric times to the end of the 4th century B.C., vol. 1 (Cambridge, Mass., 1952); Wolf, Abraham, *History of Science, Technology and Philosophy in the Sixteenth and Seventeenth Centuries* (new ed., New York and London 1951); id., *History of Science, Technology and Philosophy in the Eighteenth Century* (New York and London 1952).

Science has developed in so many directions and with such incredible exuberance in the 19th and 20th centuries that it has become almost impossible to cover it. Yet, see Darmstaedter, Ludwig, *Handbuch zur Geschichte der Naturwissenschaft und der Technik* (Berlin 1908), a list of discoveries in chronological order which requires 273 pages to cover the period 3500 B.C., to 1799, and 800 pages to cover the years 1800 to 1908; Lark-Horovitz, K., and Carmichael, Eleanor, *Chronology of Scientific Development, 1848–1948* (Washington, D.C., 1948), very short yet useful. The difficulties of writing the history of contemporary science are discussed by Sarton, George, "Remarks Concerning the History of Twentieth Century Science" *Isis,* vol. 26, pp. 53-62 (1936).

GEORGE SARTON,
Honorary President of the History of Science Society.

SCIENTIFIC MANAGEMENT. Definition.—The term *scientific management* characterizes that form of organization and procedure in purposive collective effort which rests on principles or laws derived by the process of scientific investigation, experiment and analysis, instead of on tradition or on policies determined empirically and casually by the process of trial and error. The principal phases of scientific management are: (1) Exhaustive investigation of the elements usable in collective effort—manual and machine processes, materials, tools and equipment, physical and psychological operating conditions—and their reactions in all possible relations, in order to determine the combination which for any specific purpose is most economical in technical energy—human and material; the formulation of the results of such investigation in principles and laws, and the establishment on the basis of such principles and laws of standards of procedure and result; (2) the development and maintenance of such precise and automatic coordination and control of the collective effort as to accomplish, in accordance with the established standards of procedure and result, with

economy of energy and time, any purpose of the collective effort; (3) organization of the personnel, processes, materials and equipment in such functional cooperative relations as to bring to bear in the collective effort the highest available and developable technical skill in planning, supervision and execution. See also INDUSTRIAL ENGINEERING; INDUSTRIAL ORGANIZATION AND ADMINISTRATION.

SCIENTIFIC METHOD, an investigative procedure which involves the application of principles of logic to the solution of scientific problems. In its ease of adaptability to all of the sciences, logic becomes the common denominator and reasoning tool of scientific method, with observation and experiment the means of verification of the theories thus advanced.

The Scope of Scientific Method.—The expression "scientific method" may be regarded in one or other of two different areas of interpretation, namely: (1) In a restricted sense, it is the term applied to various modes of investigation by means of which specialized knowledge is acquired in fields of research concerned with physical or natural processes (for example: physics, chemistry, astronomy, geology, meteorology); (2) In a more general sense, the term scientific method may be applied to processes of establishing the truth of widely diverse propositions of seemingly nonscientific nature (for example: in the fields of sociology, business, economics, philosophy, or law) by resort to the demonstrative and deductive methods of science. In general, scientific method entails those processes of logical reasoning by which the aggregate of all truth is rigorously established.

Experimental Science and Logic Compared.—Experimental science as a whole is concerned with methods of measurement, qualitative and quantitative; the devising of conditions under which an unknown quantity may be most accurately and expediently observed. It furnishes the auxiliary tool, the instrumentality for setting up the conditions of an investigation and observing the resultant action. Hence experiment alone does not constitute an end, but only a means to discovering the end. It supplies the data which logic subsequently construes and evaluates. The empirical method renders possible final conclusions but does not in itself propound theories. Logic is the process of drawing inferences from the phenomena scientifically observed. The methods of logic are the same for all of the sciences. And since the ultimate aim of the scientist is to establish conclusions and from these to deduce scientific laws, the principles of logic become indispensable in the evaluation of causal relationships.

Theories of Causality.—In a vast simplification of the metaphysical concepts of Aristotelianism (q.v.) or the classic theories of David Hume and John Stuart Mill (qq.v.) regarding causal origins, modern scientific method allows for but two basic interpretations of causality:

The Common Sense or Activity View of Causality.—The causal relationships here formulated follow very closely the dictates of common sense which say "every event in Nature has a natural, definable cause." This concept divides naturally into two parts, namely:

(1) If a thing has not changed for a finite length of time, it does not suddenly begin to change, unless some extraneous force or action causes it to change; in short, every change is necessitated.

This principle is admirably brought out by Sir Isaac Newton's First Law of Motion, which states: "A body in motion tends to remain in motion in a straight line with uniform velocity unless acted upon by some exterior force; a body at rest tends to remain at rest unless acted upon by some external force."

The sudden explosion of formerly quiescent chemicals is another example of this principle, since some factor such as varying temperature or pressure must have necessitated the sudden change and produced it accordingly.

(2) The common sense view of causality also subscribes to the proposition: "An identical cause produces an identical effect." In other words, given the effect of a certain cause, and repeating the experiment under exactly the same conditions, the same effect must result.

The Regularity or Uniformity View of Causality.—This viewpoint may be summarized in the two statements:

(1) There are causal laws. These laws, if exact, may be reduced to a symbolic or mathematical representation.

(2) Every event that occurs in Nature is connected with other events, occurring either prior to or simultaneously with the first, by one or more causal laws. If enough of these laws are known, the occurrence of the event may be predicted with absolute certainty.

The uniformity view thus also identifies causation with regularity.

A representative example of a causal relation easily translatable into equation form is that found in the law of falling bodies, $s = \frac{1}{2}gt^2$, which is used to predict the position of any body falling from rest under the influence of gravity alone. Under such circumstances, when the body is free from any initial propulsion, it falls with systematic regularity under uniform acceleration, and hence its position at any time t is predictable with absolute certainty. Corrections may be added to account for retardation of the body due to air resistance.

Kepler's Third Law of Planetary Motions is another excellent example of a causal relationship expressible in simple mathematical terms, namely: $P_1^2/P_2^2 \propto Ca_1^3/a_2^3$ or, in words, the squares of the periods of revolution of the planets about the sun are proportional to the cubes of the mean distances of the planets from the sun. Gravitation is again the causal factor. C is a gravitational constant which insures uniform units throughout the equation. This is the so-called "harmonic law" expressing close regularity in the solar system (q.v.).

Scientific Law and Predictability.—A scientific law is only a law when it is capable of predicting a given phenomenon with certainty and is applicable to 100 per cent of the cases involved. The almost universally designated Bode's Law (q.v.) which in astronomy expresses the distances of the planets from the sun according to a simple arithmetic and geometric progression of numbers is actually not a true scientific law. It might better be called a rule, implying only the usual course of action for the majority of cases, since it breaks down completely for the outer planets Neptune and Pluto, and does not provide a consistent geometrical series in the case of Mercury. Similarly, Sir Isaac Newton's universal law of gravitation, although remarkably without major

proven exception, finds occasional needed reinforcement from the concepts of relativity (q.v.). Gravitational theory alone fails to explain the observed motion in the perihelion of the planet Mercury, while the General Theory of Relativity accounts precisely for the residual error. Without being regarded as a replacement for the law of gravitation, Einstein's relativistic theory may be thought of as a higher approximation of accuracy thereto—or in the light of Einstein's attempts, the two theories may eventually be encompassed in a new and generalized law involving all forms of energy. Another important example of incompleteness in a scientific law exists in the dual nature of light as particle and wave (see LIGHT—*Nature of Light*). Scientific law is always subject to emendation as further facts are discovered or exceptions are found to exist.

In this requirement for absolute predictability, scientific laws may perhaps find their greatest looseness in the fields of social science. Wherever the human element is involved, a vast concomitance of individual uncertainty arises. Economic, sociological, and population-sampling laws, while entirely adequate to predict trends and indicate the expected, normal, or majority action with fair assurance, are not absolutely infallible. Even the economic law of supply and demand, while inevitable in its consequences, can be altered by unpredictable events. Inductive reasoning (see *infra*) is barred from the study of economics; the methods of deduction alone are compatible.

The pattern of mores, social codes, and ethical practices which govern human behavior can likewise be influenced by unusual circumstances. In the field of biological science, the human body is known to contain 24 chromosomes with an almost infinite possibility of genetic combinations thereof, giving rise to an incalculable number of divergent personalities. This protean complexity of the human genetic structure results in the multiplicity of traits, characteristics, qualities, attributes, idiosyncrasies and proclivities which make up the individual. Faced by this range of variables in the human behavior pattern, plus environmental circumstances, scientific method is often hard put to follow a truly representative line of investigation. But singularly enough, scientific method is especially strong in the biological sciences where unrelated variables occur in great number.

In dealing with many phases of socio-economic investigations, as in numerous instances of complex physical processes, it becomes necessary to segregate from among the vast welter of possible factors for study those items which will be of value in the establishment of meaningful conclusions. The principles of scientific method underlying the organization of facts out of apparently chaotic masses of evidence are outlined below.

DISCIPLINES OF SCIENTIFIC METHOD

Observation.—The scientific procedure of comprehending things and events, quantities, qualities, and relationships. Observation may be purely visual in nature, or achieved with the aid of suitable research instruments.

Refractory or Uncontrolled Investigation.—The observation of phenomena under conditions beyond the control of the observer. The observation of the solar corona at the time of a total solar eclipse is an example of uncontrolled investigation, since the astronomer must sometimes travel many thousands of miles to set up his apparatus in the limited geographical region of the eclipse and likewise has no control over the fleeting instants of totality. (See ECLIPSE.)

Experimental or Controlled Investigation.—In this category, the observer must be able to control all aspects of the investigation and exercise command over the variable factors concerned. He must be able to determine the time and place of the experiment. In direct contrast with the preceding example, the use of the *coronagraph* at the Harvard College Observatory-University of Colorado high-altitude station at Climax, Colorado, and similar equipment at other mountaintop observatories throughout the world provide an excellent illustration. Over extended periods of observation which are limited only by the seasonal occurrence of clouds and weather at this high altitude (11,500 feet), the sun's features may be studied instrumentally and by means of permanent equipment at any instant the sun is above the horizon and the sky is clear. By the cooperation of similar research stations around the world, and in both hemispheres, the sun may be placed under observation almost continuously 24 hours a day.

The experimental method makes possible a more reliable analysis, in that the observer may repeat the experiment over and over again at will and thus greatly lessen the probable error of his determinations. Similarly, the investigation may be more or less easily divided into parts, thus facilitating the research and making possible more accurate inference as to the connection between various phases of the experiment. The controlled investigation may be carried out under a variety of conditions and circumstances, each of which may be important to a true understanding of the problem.

Analysis and Synthesis.—These are correlative concepts, one being always the complement of the other. Analysis is an investigative approach to a problem by the resolution or separation of the whole into its constituent parts; synthesis is the process of building up a theory, or a coordinated system, by the combination of individually related facts. Figuratively, if the quantities *a, b, c, d,* are the analysis of *s,* then *s* is the synthesis of the quantities *a, b, c, d.* The two procedures bear a close relationship to the reasoning processes of induction and deduction, respectively. Two distinct types of analysis exist, which are equally applicable to the process of synthesis:

Partitive or Quantitative Analysis.—The physical division of a spatial whole. This method consists in the exhibition of a given entity as a union of material parts. A watch is analyzed partitively when it is divided into its physical components, such as mainspring, dial, and gear wheels. The chemist pursues quantitative analysis when, by the method of electrolysis, he physically separates proportionate quantities of the components of which water is made, namely two parts of hydrogen and one part of oxygen. Here the observer is concerned with the *amount* and not the *kind* of the chemical components. So long as he interests himself solely with the quantitative division of a given compound or substance into its constituent elements or stable radicals, he employs the partitive method. Should he investigate the chemical properties of the substance, however, he bridges the gap to the method of qualitative analysis. Because of their close in-

terrelationship in chemistry, the two actions are often concomitant. Quantitative analysis may be subdivided into two further classifications or criteria:

(1) Homogeneous—The analysis is homogeneous if the components are identical in nature with the substance analyzed. This is precisely a physical partition. The components need not be of the same size or shape, however, and one fact alone is important in the definition: Although the size, shape, physical properties and surfaces of the original substance may be destroyed, the intrinsic properties of the original substance are preserved and remain in the secondary portions no matter to what degree the partition is carried out. The division of a cube of sugar into smaller parts or the physical division of a gallon of water into quarts and pints are typical examples.

(2) Heterogeneous—The analysis is heterogeneous when the individual components do not belong to, or possess the same intrinsic properties as the whole. The division of a watch into mainspring, dial, and other component parts, or the physical decomposition of water into proportional quantities of hydrogen and oxygen by electrolysis are previously quoted examples of this type.

Qualitative Analysis.—The determination of the basic and functional properties of any substance or object. If, instead of listing the parts of a watch, one were to describe the characteristic appearance, composition, and qualities of the watch—that it is circular, made of metal, records the time, and so on, he has entered the field of qualitative analysis. The decomposition of sugar into its chemical elements carbon, hydrogen, and oxygen by the addition of sulphuric acid belongs to the method of qualitative analysis, which includes many chemical investigations. Qualitative analysis is the descriptive as opposed to the mensural.

Supposition and Hypothesis.—Active interrogation to discover the cause of a given event in Nature often makes resort to a preliminary supposition or hypothesis, which is proposed as an unverified conjecture in an effort to explain the basis of the unknown phenomenon, subject to ensuing proof. The working hypothesis is initially assumed to be true, as a point from which to start, but remains barren until it is successful in explaining all the facts. Without such preliminary hypotheses, all research investigations would be aimless. Therefore, any hypothesis whatsoever until put to the test is better than none. If it stands the tests, it becomes "fruitful" and no longer may be spoken of as barren. Hypotheses require great imagination and considerable familiarity with the subject concerned. In practice, there are two laws which govern the development and expression of the hypothesis:

(1) The hypothesis must contain nothing inconsistent with known facts and principles.

(2) The hypothesis must not contain postulates which are not subject to verification by empirical test.

One of the best examples of a truly fruitful hypothesis is that of the discovery of Neptune after the hypothesis had been ventured that the observed discrepancies between the calculated and observed orbits of the planet Uranus might be due to the gravitational attraction of another planet still farther out in space than Uranus. In the year 1846 this outer planet, Neptune, was actually discovered, thus completely verifying the hypothesis originally proposed. (See NEPTUNE.)

Analogy and Comparison.—Analogy is the utilization of any respect in which two or more objects agree in order to explain an unknown object or its action by reference to that whose properties are known. Scientifically, the process of analogy may be extended to the determination of the possible cause of an unknown phenomenon by its similarity to one or more other occurrences whose cause is known. The role of analogy is therefore frequently important in the formulation of a working hypothesis. True analogy is discoverable, however, only by a careful comparison of all elements involved rather than a cursory examination of a few random or isolated cases of agreement. The procedure is subject to many pitfalls where extrinsic rather than intrinsic variables are selected for comparison. As an example, the inverse square laws expressing the variation of attracting force with distance in the case of (1) magnetism and (2) gravitation are almost exactly similar. But to reason by pure analogy that the two forces are identical in nature is fallacious. This concept was once regarded as true.

Inference.—Inference is the process of deriving propositions on the evidence of other propositions whose truth is known to be established. Inference may be of two types:

Deductive.—Deductive inference is reasoning from general premises to specific derived instances thereof. The procedure involved may be summarized in the simple hypothesis "if proposition p is true, then proposition q is likewise true." As an example, "If it rains, the streets are wet." (If p, then q.) The method of deduction proceeds in the following fashion: (1) The general principle or premise, which must be true, is stated; (2) A special case is adduced as an instance of the general principle (and hence must fall under the coverage of this principle); (3) The inference, conclusion, proof, or demonstration results therefrom.

Inductive.—Inductive inference is concerned with the derivation of general propositions from the evidence of specific cases which come under the induced generalization. As reasoning from specific to general, inductive inference is exactly opposite to deductive inference.

The formal statement of the method is as follows: (1) Many particular instances with common characteristics point to the formulation of certain conclusions, in the form of general laws or principles; (2) These characteristics must be common to all instances and, theoretically, an infinite number of cases must be taken as examples and proof; (3) Accordingly, in most cases under this method of investigation, the conclusion drawn is only a probability, whose accuracy increases as the number of cases represented increases.

Idealization and Abstraction.—Since the human capacity for understanding is duly limited by the complexity of a problem which confronts it, the intricacies of many difficult problems make it necessary to simplify the aspects these present. In that process, certain of the investigation's phases must be disregarded, and the method resorted to takes the form of abstraction.

The so-called "economic man" is an abstraction. Herein, man's purely economic motives are involved, all others being forgotten. The economic man always buys the cheaper of two commodities of the same quality offered for sale; he always buys the best one of two objects at the

same price. In abstracting man's complex personal motives, the method obviously becomes one of idealization. Frictionless motion which is sometimes assumed in mechanics and physics likewise involves the principle of idealization and abstraction. In order to derive practical laws of motion, the fact is ignored that all bodies on the earth actually move in a surrounding medium, air. Where celestial bodies revolve freely in outer space, unimpaired by frictional retardation, an idealization is, in fact, the existing rule. The "frictionless" motion of Timken bearings is an idealization, for it is impossible completely to eliminate the retarding effect of friction on a rotating body.

Classification.—Classification is the activity of organizing objects unified by a common attribute or property into certain useful groupings. The process of classification is an artifice often resorted to in order to simplify the approach to a given problem by narrowing its broader elements and ramifications on the basis of categorical distinctions. The method is especially valuable in the field of biological sciences.

Proper care must be exercised in the evaluation of these distinctions. Errors in classification resulting from the consideration of superficial rather than fundamental distinctions are of widespread popular occurrence. Thus the frequent classification of whales as fish under the theory that they bear a superficial resemblance—namely that each swims in the ocean—is erroneous. Herein fundamental differences are ignored and camouflaged by environmental similarity. The whale is a mammal. Coal is often loosely defined as a mineral rather than by its true description as a fossilized carbonaceous material of vegetal origin, because of its superficial resemblance to known minerals—again the subordination of fundamental issues before more obvious ones. The sea-anemone (q.v.) and sea-cucumber (see HOLOTHURIA) were once regarded as plants, totally ignoring their basic distinction as marine animals. Breathing, combustion, and erosion are all processes of oxidation and yet cannot with proper evaluation be brought under the same classification. It is apparent that whatever quality is used as a basis for classification must form a distinct and fundamental criterion in the objects being classified.

Such are the basic evaluative processes and techniques of scientific method, the application of which has led to new discoveries in many fields of knowledge. The same investigative principles are also effectively used in criminology, law, and numerous related aspects of argumentative discourse, polemics, and debate. See also ARGUMENTATION; CAUSE; CLASSIFICATION; DEDUCTION; DETERMINISM; HYPOTHESIS; INDUCTION; KNOWLEDGE; LOGIC.

FERGUS J. WOOD,
Science Editor, "The Encyclopedia Americana."

SCILLA, sĭl'ä, town and commune, Italy, in the Province of Rizzio di Calabria, on the Strait of Messina. It is the center of a large citrus fruit and olive region. In 1783 and again in 1908 it was severely damaged by earthquakes. Opposite Scilla, near Punta del Faro, is the Garofalo whirlpool, the supposed Charybdis of ancient legend (see SCYLLA AND CHARYBDIS). Pop. (1946) of commune 4,608.

SCILLA, headland. See SCYLLA AND CHARYBDIS.

SCILLA, a genus of bulbous-rooted plants of the lily family (Liliaceae) with linear radical leaves, spreading perianth, and a leafless scape of blue, rose, or purple flowers. Cultivated species are the Siberian squill (*S. sibirica*), the Cuban lily (*S. peruviana*); the English bluebell or wood hyacinth (*S. nonscripta*).

SCILLY ISLAND, atoll, South Pacific Ocean, one of the most westerly of the Society Islands and uninhabited. It is also called Fenura Ura.

SCILLY ISLES or **ISLANDS,** sĭl'i, an archipelago, 6.3 square miles in area in the Atlantic Ocean, 28 miles from Cornwall, of which it is a part. The derivation of the name Scilly is obscure. There are some 140 islets and rocks with an area of 4,041 acres in the group; five of them, St. Mary's (the largest), Tresco, Saint Martin's, Saint Agnes, and Bryher, are inhabited. The estimated population (1954) was 1,864 (1951 census, 1,740).

Generally identified with the Cassiterides (tin islands) of the Phoenicians, the Scilly Isles are composed of granite, most of which is coarse and porphyritic, and contain a few metalliferrous veins, but little tin. The Atlantic has hollowed out caves in the cliffs, and reefs and shoals make navigation perilous in rough weather. Bishop Rock lighthouse, built in 1858 and rebuilt 30 years later, is situated on an outlying rock to the southwest, and there are lighthouses on Round Island and at Peninnis Head (Saint Mary's). The climate of the group is mild and equable, giving rise to an early flower- and vegetable-growing industry for the London market; there is also a small fishing industry. The chief town, Hugh Town, on Saint Mary's is connected with Penzance by a steamer service, and with Saint Just by air. Radio telephone and telegraph communication is maintained with the mainland. Hugh Town is also a tourist resort, and Star Castle, built in 1593, at which Prince Charles stopped in 1645 on his flight to Jersey, is now a hotel. On Tresco are King Charles' and Oliver Cromwell's castles, the ruins of a 10th century abbey, and the residence, with its famous tropical gardens, of Augustus Smith, proprietor of the islands from 1834 to 1872. Bronze Age burial mounds and prehistoric remains are found on a number of the islands, and Samson is the scene of Besant's *Armorel of Lyonesse;* Annet is a bird-breeding ground. From the time of Athelstan's gift of the islands to a group of monks in 936, the islands remained in private hands until they were handed over to the Crown in 1933.

Consult Bowley, E. L., *The Fortunate Islands* (St. Mary's 1945); Grigson, G., *The Scilly Isles* (London 1949); Vyvyan, C. C., *The Scilly Isles* (London 1953).

RICHARD WEBB,
British Information Service, New York.

SCINTILLATION, sĭn-tĭ-lā′shŭn, *in astronomy,* the apparent twinkling of the stars as their light rays pass through the Earth's atmosphere and are affected by (1) random variations in optical density produced by winds, air currents, and atmospheric turbulence; (2) optical interference (q.v.) of light rays.

Since the stars are too far away to show as disks to the unaided eye or even to the most powerful telescope, they act as point sources of light. On entering the Earth's atmosphere, the component rays of color are refracted in different amounts, but reach the Earth's surface over paths differing only slightly. In-phase and out-of-phase overlapping between closely adjacent light waves causes reinforcement of some colors and elimination of others. As a result, the stars seem to fluctuate in both intensity and color.

By contrast, all of the planets visible to the unaided eye are close enough to the Earth to reveal perceptible disks as seen in large telescopes. Their rays thus act more nearly as beams than as thin pencils of light. As these planetary rays enter the Earth's atmosphere, they traverse a greater multiplicity of paths, avoiding much of the mutual interference which affects light from a star. A general blending and averaging out of interference effects occurs in planetary images to produce light sources of more or less constant intensity. In consequence, the planets, except when near the horizon, usually shine with a steadier light than the stars.

Scintillation varies with the optical depth and density of the atmosphere; hence even the stars twinkle less when seen from a high mountain or when directly overhead in the zenith. When viewed on or near the horizon, through a longer atmospheric light path and a layer of air in which the density and turbulence are greater, they tend to sparkle and, especially when seen through a telescope, may dance and waver noticeably under the effects of strong air currents.

In physics, scintillation is the name given to the action of certain fluorescent substances, notably impure zinc sulphide, in giving off flashes of light when exposed to radioactive emission (see RADIOACTIVITY). Although such flashes may persist for only about one millionth of a second, they form the basis of many types of scintillation counters and radioactivity detectors.

FERGUS J. WOOD.

SCINTILLATION COUNTER, a device for detecting the presence of radioactive energy by the use of a large crystal of zinc sulphide, sodium iodide, or other radiation-sensitive material (phosphor), which when struck by radioactive particles, gives off minute flashes of light. Such crystals are artificially grown, and have had purposely introduced into them very small amounts of impurities such as one ten-thousandth part of a copper salt or a trace of thallium.

The impact of radioactive particles is transformed by the crystal into tiny bursts of light, which are amplified by a photomultiplier tube. Use of a series of electron-emitting surfaces in this tube permits billionfold amplification of each light flash into an electrical impulse capable of registration by a buzzer, blinking light, or meter. Radioactive alpha and beta particles (see RADIOACTIVITY) may be measured by this means, at a rate up to a million a second, where inorganic phosphors are used.

Liquid scintillators are also available, as well as organic phosphors capable of response to impulses of a few billionths of a second duration, but giving less accurate energy measurements than those derived from the use of inorganic crystals. In a gamma-ray type of scintillation counter, a crystal of trans-stilbene is employed. Giant laboratory scintillation counters are used to investigate atomic structure, especially the nature of the neutrino, and to detect pi-mesons. The scintillation counter is also used in uranium prospecting, the detection of radiation hazards, and in biological and medical tracer research.

Science Editor, "The Encyclopedia Americana."

SCIO, the Italian name for the island of Chios (q.v.).

SCIOPPIUS, sī-ŏp′ĭ-ŭs, **Kaspar** (Latinized form of KASPAR SCHOPPE), German classical scholar: b. Neumark in the Palatinate, May 27, 1576; d. Padua, Italy, Nov. 19, 1649. He received his education at Heidelberg and at Altdorf, and before the age of 21 had published several learned books, the most noted being his *Verisimilium Libri Quatuor,* and *Suspectae Lectiones,* which attracted the attention of Pope Clement VIII. During a visit to Italy in 1598 he renounced Protestantism, and became a protégé of the Vatican. He is said to have written more than 100 books, most of them under an assumed name, satirizing the leaders of the Protestant movement. The first person whom he attacked was the illustrious Joseph Justus Scaliger (1540–1609), against whom he launched his *Scaliger Hypobolimoeus* (1607), in which he also assailed Henry IV. In 1608 he published more than 20 pamphlets against the Protestants, urging the Roman Catholic powers to exterminate them. Among his later books the most notable are *Grammatica Philosophica* (1628), and *Paradoxa Literaria* (1628).

SCIOTO, sī-ō′tō, river, Ohio, rises in Auglaize County, flows east for a few miles, then south to the Ohio River, which it enters near Portsmouth. Other cities on its banks are Columbus, Circleville, and Chillicothe. It is about 237 miles long, is navigable for about 130 miles, and for 90 miles feeds the Ohio and Erie Canal It flows through a fertile valley.

SCIOTO COMPANY, The, in American history, a land-speculating organization formed in the eastern states in 1787 for the purchase of territory along the Ohio and Scioto rivers. John Cleves Symmes, Joel Barlow, and William Duer, of New York, were largely interested. The organizers at first bought lands of the Ohio Company and appointed Barlow their agent in Europe to make sales of them and to induce immigration. Barlow had been in England previously on similar business for the Ohio Company. Symmes parceled out the lands to other parties, the tract which now embraces the city of Cincinnati falling to the share of Matthias Denman, Robert Patterson, and John Tilson, of New Jersey. As a result of Barlow's activities 218 emigrants sailed from Le Havre to settle on those lands, Feb. 19, 1790. About 50 of them settled at Marietta and the remainder formed the Gallipoli's settlement. The emigrants suffered from lack of promised supplies and inability to get clear titles to their lands, and

the company, failing to meet its obligations, was charged with swindling.

SCIPIO AEMILIANUS AFRICANUS MINOR NUMANTINUS, sĭp′ĭ-ō ē-mĭl-ĭ-ā′nŭs ăf-rĭ-kā′nŭs mī′nēr nū-măn-tī′nŭs, **Publius Cornelius** (known as SCIPIO THE YOUNGER), Roman general: b. 185 B.C.; d. Rome, 129 B.C. The second son of Lucius Aemilius Paullus Macedonicus, he was adopted by Publius Cornelius Scipio Africanus, the childless elder son of Publius Cornelius Scipio Africanus Major (Scipio the Elder). Scipio participated in the Battle of Pydna (168), in which his natural father concluded the Third Macedonian War (171–167), and then served as military tribune in Spain (151), where he won distinction. The outbreak of the Third Punic War (149–146) saw Scipio still a subaltern, but his gallant conduct in Africa and his general's commendation gained for him the consulate (147) and command of the Roman forces besieging Carthage. In 146 he captured Carthage, which he razed (amid tears, it is said), selling the survivors into slavery. He organized the Punic domains into the Roman province of Africa and returned to Rome, where he celebrated a triumph. To his inherited agnomen Africanus he added the additional agnomen Minor (the Younger) to distinguish him from his grandfather.

Scipio became censor in 142 and served on legations to Greece and the Near East during either 141–140 or 136–135. Re-elected consul for 134 and assigned Spain as his province, he concluded a war there by capturing Numantia (133) after a long siege, receiving another triumph in Rome and another agnomen Numantinus (132).

Perhaps more important than Scipio's military exploits were his patronage of the littérateurs who constituted the influential Scipionic Circle. His acquaintance with Greek literature and philosophy was above that of his Roman contemporaries, and he had great oratorical attainments. In politics he championed the conservative party against the democratic party, led by his brothers-in-law and first cousins, Tiberius Sempronius and Gaius Sempronius Gracchus (q.v.). Scipio's sudden death after political disorders has been ascribed to assassination, but for this no evidence exists.

Consult Lincke, E. M., *P. Cornelius Scipio Aemilianus* (Dresden 1898); Brown, R. M., *A Study of the Scipionic Circle* (Scottdale, Pa., 1934); Bilz, K., *Die Politik des P. Cornelius Scipio Aemilianus* (Stuttgart 1936).

P. R. COLEMAN-NORTON.

SCIPIO AFRICANUS MAJOR, sĭp′ĭ-ō ăf-rĭ-kā′nŭs mā′jĕr, **Publius Cornelius** (known as SCIPIO THE ELDER), Roman general: b. 237 B.C.; d. Liternum, Italy, 183 B.C. Destined to be the most renowned Roman of his generation, the youthful Scipio saved his father's life in the Battle of the Ticinus River (218), which inaugurated the Second Punic War (218–201) in Italy. As military tribune, he rallied the Roman remnant after the disastrous defeat at Cannae (216). After acting as aedile (212), Scipio went as proconsul (210) to Spain, where he soon captured Cartagena (209), the chief Carthaginian base. Then by spirited leadership, by revising Roman military tactics, by attracting Spanish allies to his side, and by brilliant campaigning, he so completely conquered the Carthaginians during 208–206 that Punic control of the peninsula collapsed and the Romans acquired almost all Spain (and afterward Portugal) as provinces. Returning to Rome, Scipio became consul in 205 and received Sicily as his province. There he organized the Roman invasion of Africa, which he began in 204. Scipio was so successful in his sieges of Carthaginian cities and in his battles against Punic armies that the Carthaginians sued for peace, summoning Hannibal, their greatest general, from Italy in 203. Hannibal's return inspired renewal of hostilities, which ended in the Battle of Zama (202), where the Romans under Scipio conquered the Carthaginians commanded by Hannibal. Scipio dictated harsh terms of peace in 201 and returned to Rome, where he celebrated a triumph and received the surname Africanus, to which later Romans added Major to distinguish him from his grandson, whose capture of Carthage in the Third Punic War won him the surname Minor.

Chosen censor (199), named chief of the Senate (199, 190), re-elected consul (194), Scipio tried his hand at making policy, but with less success than he had won in waging war, since his stanch philhellenism found few supporters in the Senate, which prescribed foreign policy. But his military experience was utilized in 190, when he served as legate to his brother Lucius, who conducted the war against King Antiochus III the Great (r. 223–187) of Syria, whose crushing defeat at Magnesia in Asia Minor (189) was due to Publius' plans, though illness prevented the latter's participation in battle.

Scipio's return from Asia was robbed of acclaim by an accusation that he and his brother had accepted bribes from Antiochus. Though the truth has been clouded by conflicting testimony, it is evident that the prosecution (187–185) was engineered by his political enemies. After a dramatic acquittal, Scipio retired to his Campanian villa at Liternum, where he passed his last years in privacy.

P. R. COLEMAN-NORTON.

SCIRE FACIAS, sī′rē fā′shĭ-ăs, a judicial writ requiring the party to whom it is directed to show cause why the plaintiff should not receive the relief which he has requested. This proceeding is used most often to revive a judgment but may also be used to have a record, such as a patent, declared invalid or corrected. It may also require a person to show that he has a right to perform an act despite the plaintiff's claim of expected injury. The writ is obtained on the basis of the plaintiff's petition, which must show the material facts justifying the issuance of the writ. The recipient of the order may serve pleadings in defense just as he might to an ordinary complaint; on the return of the order, a hearing or trial will be held to determine whether the plaintiff, in fact, deserves the relief asked. The term is disappearing from legal use, but the benefit of it still exists under the more common name of "an order to show cause."

SCIRPUS, sûr′pŭs, a large genus of rushlike or grasslike plants of the sedge family (Cyperaceae), universally distributed and commonly known as bulrushes or club rushes. Many species are partially or completely of aquatic habit. They are annual or perennial, some small and some

large. The small, perfect flowers have usually a perianth of bristles, and are in spikelets, with or without subtending involucres, and mature into variously shaped achenes. The spikelets are either solitary or in groups, and are very commonly umbelled. These plants are often called rushes or bulrushes, and are common in wet woods or swamps, and often rise conspicuously out of shallow water. *Scirpus cyperinus,* the brown wool-grass, has immense drooping umbels of spikelets, supported on slender cylindrical stems. It is perennial, two to six feet high, with curving grass-like leaves, and is a familiar plant at the edges of forest ponds, growing in colonies. *S. cernuus,* one of the few species cultivated, is a good pot-plant, having long drooping stems, forming a dense mat at the base, and with solitary spikelets. *S. lacustris,* the great bulrush of the Old World, is known as the mat-rush, because it was employed for weaving into mats, chair-bottoms and cordage. It is a curious aquatic plant whose very smooth, blue-green, tall stems bear at the top flexuous umbels of spikelets. This species and the allied *S. tatora,* are the «tulés» (q.v.) of the American Southwest.

SCIRRHUS, or **HARD CANCER,** a scirrhous cancer. See CANCER.

SCISSOR-BILL, a bird. See SKIMMER.

SCISSOR-TAIL, a beautiful flycatcher (*Milvulus forficatus*) of the lower Mississippi Valley, which receives its name from its habit of crossing and recrossing in flight the two very long outer feathers of its tail. It is white with dark wings and a roseate flush upon its breast and on the lining of its wings, and is exceedingly graceful. Its general habits are those of the flycatchers (q.v.).

SCISSORS. See CUTLERY; HARDWARE INDUSTRY IN AMERICA.

SCLEROMETER, scle-rom'e-ter, an instrument for the accurate determination of the hardness of minerals. In one form the mineral is mounted on a small carriage moving along a track. Upon this is a lever with weighted diamond point which is in contact with the surface to be tested. Weights are then added to a pulley connected with the carriage until they are just sufficient to move the carriage and produce a scratch on the mineral. In the microsclerometer of Jagger hardness is ascertained with any one of four variables: rate, weight, depth or duration (see *Amer. Jour. Sci.,* IV, 399, 1897). The sclerometer shows that different faces of crystals vary in hardness. By rotating a crystal through 180 degrees and recording the weight required to produce a scratch for each 10 degrees, it is possible to secure data from which the "curve of hardness" can be constructed. Jagger has determined the absolute hardness of some of the minerals in the Mohs scale, assuming a value of 1,000 for corundum, as follows: topaz 152, quartz 40, orthoclase 25, apatite 1.23, fluorite .75, calcite .26, gypsum .04.

SCLEROTIC, SCLEROTICA, or **SCLEROTIC COAT.** See EYE.

SCOLECIDA, skō-lĕs'ĭ-dą, a group of worms and worm-like animals, mostly internal parasites, term now used only in a general way, as its members have been more scientifically distributed in classification in the phyla *Platyhelminthes, Nematohelminthes,* etc.

SCOLECITE, skŏl'ę-sīt, a mineral belonging to the natrolite group of the zeolite family. It is a hydrous silicate of aluminum and calcium, $CaAl_2Si_3O_{10} + 3H_2O$. When heated before the blowpipe it swells and sometimes curls up like a worm, to which property it owes its name, from the Greek *skolex,* a worm. It then fuses easily to a white, blebby enamel, thus distinguishing it from natrolite, which fuses with equal ease and without intumescence to a colorless glass. Its crystal habit is slender-prismatic and much resembles natrolite. Its crystals are, however, horizontally striated on the prisms and are monoclinic twins, the twinning being revealed by feather-like diverging striations on the clinopinacoid, while natrolite crystals are orthorhombic and show vertical striations in the prismatic zone. Its snow-white or transparent, vitreous crystals are usually clustered in diverging groups. It is also found massive or in radiated nodules. It is a secondary mineral usually in trap or amygdaloid. Among the best known of its many localities are Poona, British India, and Berufiord in Iceland; it has been found sparingly in the United States in the Palisades of the Hudson and at Golden, Colo.

SCOLLARD, Clinton, American novelist: b. Clinton, N. Y., 18 Sept. 1860; d. 19 Nov. 1932. He was graduated from Hamilton College in his native place and was a professor of rhetoric and English literature there 1888–96 and 1911–12. He also studied at Harvard and Cambridge, Eng. He traveled extensively, and from the last-name date devoted his entire attention to literary pursuits. His early work was mainly verse of a light and musical character evincing great command of metres, but with no very salient characteristics. His later verse showed a marked increase of strength as well as melody, while the earlier facility later became an almost faultless technique. The lyric was his especial field, although he now and then attempted epic forms. In his later years he produced several noteworthy historical romances. Among his books of verse may be cited 'Pictures in Song' (1884); 'With Reed and Lyre' (1886); 'Old and New World Lyrics' (1888); 'Songs of Sunrise Lands' (1892); 'Lyrics of the Dawn' (1900); 'The Lutes of Morn' (1901). His most important novels are 'A Man at Arms' (1898); 'The Son of a Tory' (1900); 'The Cloistering of Ursula' (1902); 'Lyrics of the Dawn' (1902); 'Count Falcon of the Eyrie' (1903); 'Footfaring' (1904); 'The Lyric Bough' (1904); 'Ballads of Valor and Victory,' with Wallace Rice (1904); 'Lyrics and Legends of Christmas-tide' (1904); 'Odes and Elegies' (1905); 'A Southern Flight,' with F. Dempster Sherman (1906); 'Easter Song' (1907); 'Voices and Visions' (1908); 'Pro Patria' (1909); 'Chords of the Zither' (1910); 'The Vicar of the Marches' (1910); 'Songs of a Syrian Lover' (1911); 'From the Lips of the Sea' (1911); 'Lyrics from a Library' (1913); 'Poems — Selected' (1914); 'The Vale of Shadows and Other Verses of the Great War' (1915); 'Italy in Arms and Other Verses' (1915); 'Ballads Patriotic and Romantic' (1916); 'Let the Flag Wave and Other Verses'

(1917); *Epic of Golf* (1923); *Songs of Summer* (1927); *Lyrics of Life* (1928); *Lyrics of Florida* (1929); *The Crowning Years* (1929); *Songs out of Egypt* (1930).

SCOLOPACIDAE, skŏl-ō-păs'ĭ-dē, a cosmopolitan family of wading birds, comprising the snipes, sandpipers, curlews and allied genera. The bill is long, very slender and flexible. They frequent bogs and marshes or the banks of rivers and ditches, where they probe the ground for worms, insects and testaceous mollusks. In the most modern classification these groups are combined with the plovers, under the broader name *Charadriidae,* of which all but the plover (*Charadriinae*) constitute the subfamily Scolopacinae. Consult Evans, *Birds* (New York 1900).

SCOLYTIDAE. See BARK-BEETLES.

SCOMBRIDAE, skŏm'brĭ-dē, a family of percomorphous fishes, comprehending the mackerel (q.v.) and its allies. The body has an elongated fusiform shape, oval in cross-section, with a conical pointed head and deeply forked caudal fin with falcate lobes. The scales are minute and anteriorly form a peculiar area known as the corselet, and the prominent lateral line takes a wavy course for its entire length. The mouth is large and armed with strong, sharp teeth, the eye large and the gill-slits extensive and free. Of the fins the pectorals and ventrals are small, the former situated high on the sides and the latter on the belly nearly or quite beneath them; the spinous dorsal is far forward and supported by slender spines; the second dorsal and anal are of similar shape and usually situated near the level of the vent, and each is continued to the base of the tail by a series of small detached finlets. The caudal peduncle is slender and bears lateral keels. The colors are generally metallic steel blue above, marked with bands, streaks or spots of black or yellow and silvery white or golden below. Internally the pyloric caeca are numerous and the swim bladder may be present or absent. The flesh is oily and a streak of deep red muscle extends along either side and is sharply distinguished from the remaining pale muscles. All of the mackerels are extremely active, predaceous, pelagic fishes, which roam far and wide over the sea in large schools and often approach the coasts to spawn. They are especially well adapted by the form of the body for rapid swimming, and resistance to the water is much lessened by the completeness with which all fins and other prominences can be depressed into recesses, so that they become exactly flush with the surface. The number of genera and species is not great, about 12 of the former and 60 of the latter being recognized, but most of them are widely distributed and have occurred or are likely to occur in our waters. Besides the mackerel, some of the most important are the Spanish mackerel, bonitoes and tunnies or horse mackerel. Consult Jordan and Evermann, *American Game and Food Fishes* (New York 1902).

SCONE, skoon, Scotland, a village in Perthshire, on the north bank of the Tay, a little above Perth, famous as having been the seat of one of the most noted Scotch abbeys. Scone is first mentioned in the beginning of the 10th century and in its abbey, built probably about the same period, was located the famous stone, according to tradition "Jacob's Pillow," on which the kings of Scotland were crowned, and which was carried by Edward I of England to Westminster Abbey where it rests under the coronation chair.

SCOPAS, skō'pas, Greek sculptor: b. Paros, and flourished between 395–350 B.C. He was the son of Aristandros, a sculptor in bronze, and went to Athens about 377 B.C., where he lived about 25 years. He belonged to the Later Attic School of which Praxiteles was another distinguished member. For the temple of Athena Alea at Tegea he made the sculptures of both pediments and the statues of *Asklepios* and *Hygieia* for the interior. In various parts of the Peloponnesus he executed statuary, as for instance, the *Asklepios* at Gortys, in Arcadia, a *Herakles* at Sicyon; an *Athena Pronaos* and an *Artemis Eucleia* at Thebes; also a group *Eros, Himeros and Pothos* (Love, Longing and Desire) at Megara. One of his most famous statues was the *Bacchante* ornamenting the theater of Dionysus at Athens; another was the *Niobe* of which the copy of the lost original is in the museum at Florence.

SCOPES CASE. In March 1925 the legislature of Tennessee passed a law forbidding the teaching in the public schools of the state of "any theory which denies the story of the Divine creation of man as taught in the Bible," and the teaching "instead that man is descended from a lower form of animals." John T. Scopes, a teacher of biology in the high school of Dayton, was indicted on the charge of transgressing this law, and was brought to trial on July 10. The prosecution was conducted by the attorney-general of the state, assisted by W. J. Bryan. Scopes was defended by Clarence W. Darrow, Dudley F. Malone and Arthur G. Hayes. After a spectacular trial ending July 21, Scopes was found guilty and fined $100. Five days later Mr. Bryan suddenly died, a grim aftermath to a trial that had roused nationwide ridicule. In 1927 the state appellate court reviewed the case and reversed the verdict, preventing an appeal to the United States Supreme Court.

SCOPOLAMINE, skō-pŏl'ą-mēn, Hyoscine, an alkaloid obtained from a number of Solanaceous plants, especially *Datura Metel.* It was discovered in 1888 by Schmidt in *Scopolia atropoides.* It is usually obtained as a liquid, but can be crystallized from ether, melting point 59°C., slightly soluble in water, levorotatory. It has the formula $C_{17}H_{21}NO_4$, and is chemically *l*-tropylscopine, an ester of *levo*-tropic acid with the amino alcohol scopine. Scopolamine forms many crystalline salts, the hydrobromide ($C_{17}H_{21}NO_4 \cdot HBr + 3H_2O$) being most common in medicine.

SCORE, *in music* the original transcript of a musical composition, with the parts for all the different voices or instruments arranged and placed in juxtaposition; so called from the practice of drawing the bar through all the parts. As a general rule the highest part should be placed uppermost, the others under it and each other, according to the lowness of the part.

All the parts of a chorus should be placed together: the soprano standing on the upper staff, the mezzo or second soprano (if any) on the one immediately below it, and so descending in the following order—contralto, second contralto (if any), tenor, second tenor (if any), bass and, lowest of all, second bass (if any). A good musician is able to form a pretty close idea of the effects the composer intends to produce by carefully reading the score. See MUSIC.

SCOREL, Jan van. See SCHOORLE, JAN VAN.

SCORESBY, skōrz'bĭ, **William,** English Arctic explorer: b. Cropton, near Whitby, Yorkshire, Oct. 5, 1789; d. Torquay, Devonshire, March 21, 1857. He was the son of a whalefisher of the same name and made his first voyage with his father in the *Dundee* when but 10, and for eight years after 1803 they made annual voyages, young Scoresby studying at the University of Edinburgh between voyages. In May 1806 in the *Resolution* they reached the highest northern latitude (81° 30′) then attained. The elder Scoresby resigned his command of this ship in 1811 and was succeeded by his son, who continued the northern whaling expeditions and at the same time made observations of the electrical phenomena of the Arctic regions and it was through his reports that the government was induced to send out the Arctic expedition under Sir John Ross in 1817. In 1823 after 17 voyages to the Greenland and Spitsbergen regions he quit whalefishing, and several years later became a divinity student at Queens College, Cambridge. He was graduated in 1825, ordained in that year and subsequently held various livings and became well known for his philanthropic labors. He visited the United States in 1842 and in 1848, and made a voyage around the world in 1855–1856 in the pursuit of magnetic researches. He published *History and Description of the Arctic Regions* (2 vols., 1820); *Journal of a Voyage to the Northern Whale Fishery, Including Researches and Discoveries on the Eastern Coast of Greenland* (1823); *Discourses to Seamen* (1831); *Magnetical Investigations* (1839–1852); *Zoistic Magnetism* (1850); *The Franklin Expedition* (1850); *My Father: Being Records of the Adventurous Life of the Late William Scoresby, Esq.* (1851).

SCORODITE, a mineral occurring in small leek-green to reddish-brown quartzoid crystals of orthorhombic form associated with the arsenical minerals of Europe, Siberia, Brazil, Utah and many other localities. It is also found as a pale green incrustation around hot springs, occurring thus in Nevada and the Yellowstone Park.

SCORPIO, *in astrology* the "accursed constellation," the "false sign," ominous of war, discord and woe. It is of "watery triplicity," and is attended at its setting by tempests and by autumnal diseases.

In astronomy the eighth sign of the Zodiac, its symbol is ♏. The main star of this constellation is Antares, a red star of the first magnitude, which has a green companion of the seventh.

SCORPION FLY, a neuropterous insect of the family Panorpidae, in which the head is prolonged to form a beak. The body is long and slender. The legs are long, the tarsi being five-jointed; and two spur-like processes exist in the tibiae or shins. They have four, multiveined wings. The name scorpion fly is derived from the appendages attached to the abdomens of some species. In certain species the sixth and seventh joints of the abdomen are attenuated and capable of extensive motion; while the last joint forms a pair of forceps resembling those of the earwigs. When at rest this tail is curled over the back, but when irritated the forceps are used as weapons of offense or defense. These insects are found chiefly in damp situations, under bushes, etc.

SCORPIONS, predaceous arthropods of the order Scorpiones (or Scorpionida), the most primitive land arachnids, and the oldest, being known from Silurian fossils, are reputed to have been the first land animals. These flattened, distinctly segmented creatures are characterized by the presence of a poisonous sting on the end of the abdomen, the five terminal segments of which are sharply narrowed to form a long, ringed, moveable postabdomen or "tail." In life the tail is curled over the back so that the curved, spine-like sting is in position to strike insects, spiders, and other small living animals that serve as food. The cephalothorax, which presents above a flat carapace bearing a pair of large median eyes and a group of two to five small eyes on each side margin, is broadly joined to the abdomen as in solpugids and pseudoscorpions, not narrowed to a slender waist as in such distant relatives as whip scorpions and spiders. The four pairs of walking legs are similar and relatively slender. Held out in front to test the terrain is a pair of long, robust pedipalpi provided with stout pincers similar to those of lobsters, which are used to hold the prey. A small but strong pair of chelicerae in front of the mouth aid in crushing the body of the victim, preparatory to predigesting and pumping the liquid through the simple mouth into the digestive tract. As in all arachnids, the genital products are voided through a pore which opens on the ventral face of the second abdominal segment in both sexes. Immediately behind are a pair of pectines, comblike organs found only in scorpions and thought to have a sensory function.

Scorpions are solitary, nocturnal creatures that attack each other as readily as any other suitable prey. The male performs a sort of courtship by grasping the hands of the female and rubbing his tail against hers, after which copulation occurs. The male is often attacked and killed by the female. Whereas most arachnids lay eggs, the scorpions are viviparous, bringing forth living young. The newly born scorpions mount the back of the mother and stay there until after their first molt, usually for about a week. During this period they consume the food stored in their bodies. The ridiculous belief that these weak, tiny babies feed upon the body of the mother has no basis in fact. No less a fable is the classic story that scorpions commit suicide by stinging themselves when they are helplessly cornered or surrounded by a ring of fire. During frantic efforts to escape the ring, the victim stings at random, sometimes striking its own body before succumbing to the heat of the flames.

The venom of most scorpions causes mild to severe local reactions at the site of the sting. A

few species of relatively small size and belonging mostly to the family Buthidae are known to cause pronounced neurotoxic reactions in man and warm-blooded animals. Most notorious of all is the Durango scorpion, *Centruroides suffusus,* which has caused many deaths among children in the Mexican city of Durango. Paving of the streets, improvements in sanitation and the wearing of shoes have sharply reduced the danger from this species, which abounds in the area and often enters houses. Two allied species occur in Arizona where they have gained a most unsavory reputation with several recorded fatalities. Serums are available that are very effective in alleviating the severe symptoms.

Scorpions abound in humid tropical areas and in hot deserts where they are represented by many species. The giants are great black creatures from tropical Africa frequently seven inches long and the average size for the whole order is about half that length. Thirty or more species are found in the United States, chiefly in the south and southwest, but some penetrate north to Virginia in the east and even farther north in the west, where they range into British Columbia, Alberta, and Saskatchewan.

Other arachnids frequently associated with the true scorpions because of their common names but which for the most part are not closely allied are the following: The pseudoscorpions (order Chelonethi) are tiny forms rarely exceeding one-fourth inch in length that resemble scorpions but have the abdomen rounded behind and without trace of whip or tail. The wind scorpions or solpugids (order Solifuges) are active, tailless creatures notable for the tremendous size of their chelicerae. The whip scorpions (order Pedipalpi), narrow waisted types lacking a caudal sting, are a somewhat heterogeneous group, some having a slender, jointed, whiplike tail and other tailless ones that have the first legs tremendously elongated into lashlike whips.

Willis J. Gertsch,
Associate Curator, Department of Insects and Spiders, The American Museum of Natural History.

SCORZONERA, a genus of composite plants with numerous species, chiefly indigenous to the Mediterranean regions. The flowers are yellow or rarely rose-colored, having many series of involucral bracts, plumose and unequal pappus, and achenes without a beak and generally wingless. *S. hispanica,* sometimes known as viper's grass, has long been cultivated for its tapering, fleshy, edible roots, the dark-brown skins of which have caused it to be called black salsify. The leaves are long and lanceolate with waving edges. Other species are also cultivated for their roots.

SCOT, skŏt, or **SCOTT,** Michael, a medieval Scottish scholar and man of science: b. probably about 1175; d. probably about 1234. He is said to have studied at the universities of Oxford, Paris and Bologna. After a period in the service of Frederick II at Palermo, he continued his studies at Toledo, where he learned Arabic. On leaving Toledo he again repaired to Sicily, where he was closely associated with the Emperor Frederick, to whom he was appointed astrologer. He took orders, and was appointed by Honorius III to the archbishopric of Cashel in Ireland, but declined the post. He was at Oxford in 1230, probably sent by Frederick to bring before the university the translations of Aristotle made by himself and others. Scot was a scholar learned in the science of time, but has been transformed by legend into a magician. As such he is referred to by Dante (*Inferno,* canto xx) and Boccaccio (*Decameron*), and he plays a prominent part in the popular superstitions of the border districts of Scotland. Many works are attributed to him, of which the following have been printed: *Liber Physiognomiae Magistri Michaelis Scoti* (1477); a Latin translation of Aristotle's *De Animalibus* (1496); *Quaestio Curiosa de Natura Solis et Lunae* (1622), on alchemy; and *Mensa Philosophica* (1602), anglicized as *The Philosopher's Banquet* (1614).

SCOT, Reginald or **Reynold,** English writer: b. Scotshall, Kent, probably about 1538; d. 1599. He was a student at Oxford, but returned home without taking a degree and devoted himself to the study of old and obscure mystical authors and the pleasures of gardening. The work on which his reputation is founded is entitled *The Discovery of Witchcraft* (1584), and was directed against the belief in witchcraft, alchemy, astrology and other prevalent superstitions of his time. King James I ordered the first edition of the book to be burned by the common hangman, and attempted a reply to it in his *Demonology.* Refutations were also published by Meric Casaubon, Joseph Glanvil and others.

SCOTCH FIR, or **SCOTCH PINE.** See Pine.

SCOTCH or **SCOTS LAW,** the system of jurisprudence and judicial practice as developed in Scotland. Ancient Scotch law bore a marked resemblance to the law of England, but changes developed so that the two systems differed to a considerable extent as early as the end of the 16th century. Shortly before this the Court of Session, which had been established more than a century before, was abolished and another court, known as the College of Justice, was substituted. The system of legal procedure adopted by this court was modeled after the Roman law, and the judges showed a marked preference for Roman substantive law also. As a result the differences between Scotch and English law grew greater as time progressed, and although in recent years legislation has brought the legal systems of both countries more into harmony, there still exists considerable divergence in procedure, substantive law and terminology. For instance, the term "pursuer" as used in Scotch law is equivalent to "prosecutor" or "plaintiff" in English law. The pleading of the pursuer in criminal actions setting forth the material grounds of the action is called the "condescendence." Offenses are divided into two classes:

«delicts» and «quasi-delicts,» nearly resembling torts in English law. Cases often occur in which it is almost impossible to differentiate between delicts and quasi-delicts. Scotch law divides property into heritable and movable, in marked contrast with English law, which divides it into real and personal, Contracts by the Scotch classification are divided into three classes: Real, consensual and quasi-contracts. A consideration is not essential to the validity of an unsealed contract. «Process» has a much wider application than in English law, being practically equivalent to «practice» or «procedure.» In the law of sales, no distinction is made between conditions and warranties, and the statute of frauds has no application. The law of divorce differs considerably from that of England, the consent of parents not being essential to the validity of marriages of minors; an absolute divorce may be secured by either party for mere desertion (called non-adherence), as well as for adultery, in which latter case the parties may both remarry except with the paramour if mentioned in the decree. Formerly jurisdiction in divorce proceedings was vested in a body of commissaries, but by statute this was changed so that it now vests in the Court of Session.

In Scotland few crimes are constituted by statute, the common law being so construed that if a judge directs an act to be a crime and a jury convicts, such act is a crime. In the past this has served as an instrument of political oppression, but such is apparently not its effect to-day. The summons goes into considerable detail, and is regulated by the Act of 1850. The practice of including the grounds of the action in the summons has been discontinued, such grounds now being contained in the condescendence and pursuer's plea in law annexed to the summons. The usual form of accusation is by indictment drawn by the public prosecutor, and ordinarily a grand jury is impaneled in cases of treason only. Private prosecutions are rare. The old procedure by criminal letters has been abolished. A copy of the indictment, with a list of the witnesses, must be served on the defendant. An action in the Court of Session now commences with a summons by the pursuer. The statement of the defender is called his defenses. The procedure in this court was amended by the Court of Session Act of 1868. The pleadings in the Sheriff's Court are similar to those in the Court of Session, and the procedure is governed by the Sheriff Courts of Scotland Act of 1876. One of the distinctive characteristics of Scotch criminal law is the «not proven» verdict of the jury, which corresponds to the *non-liquet* of the Roman law, and which is permissible in certain cases. In legal effect it is equivalent to «not guilty,» and bars any further action on the same charge, but it falls far short of an acquittal on the reputation of the defendant. Criminal procedure in Scotland was much simplified by an act passed in 1887.

The ordinary appellate tribunal in Scotland for decisions of superior courts and of the lords ordinary is the Court of Session, sitting in two divisions. In criminal cases appeals from inferior courts go to the Court of Session sitting in the High Court of Justiciary. Since the year 1707 the House of Lords has been the final appellate tribunal for Scottish civil causes, but has never acted in criminal cases. See SCOTLAND—*Political Constitution.*

The Court of Admiralty of Scotland was continued at the Union in 1707 for the determination of all maritime cases within the jurisdiction of that court, but in 1830 its civil jurisdiction was transferred to the Court of Session and the Sheriff's Court. The last-named court has also limited criminal jurisdiction.

Jury trials were first used in Scotland for certain forms of civil cases in the 19th century, but are not frequent to-day.

SCOTCH MUSIC. Much conjectural matter has been written about the origin of Scotch music, discussing, among other questions, whether it was the creation of one of the artist favorites of James III, or was brought over and naturalized by David Rizzio. That much of it is as old at least as the 16th century was proved by a manuscript collection of the tunes in a handwriting and notation which brought them close back to that period. This collection, known as the 'Skene Manuscript,' was edited by a man of scholarly attainments who had devoted himself to musical study — William Dauney, F.S.A., Scotland. His conclusions on their value as preserving the music of the country in its original purity are «The favorable contrast which many of the Scotch airs therein contained present to the dull, tiresome, meretricious productions which from time to time have been palmed off upon the public under that name, and the vitiated copies of the same tunes which have been handed down by tradition alone, are the most gratifying results of its discovery. We are now no longer at a loss for a standard by which we can test the genuineness of our national music, distinguishing the true from the false, the pure ore from all admixture of baser metal.» One of the most prominent features of the Scottish music is the prevalent omission of the fourth and seventh in the scale, and the consequent absence of all semitones; another is the substitution of the descending for the ascending sixth and seventh of the minor scale. Modulation often takes place between the major key and its relative minor, and the melody keeps ever true to the diatonic scale of the principal key, no accidentals being introduced. Many airs open in the major key and close on the minor. Closes are not confined to the tonic, and are found on the third, fifth and sixth, and in Highland music on the second of a major and the seventh of a minor key. Consult Thomson, G., ed., 'Melodies of Scotland, with symphonies and accompaniments, by Pleyel, Kozeluch, Haydn, Beethoven, Hummel and Weber' (6 vols, 1793–1841); Graham, G. F., 'The Songs of Scotland,' and Fulcher, 'Lays and Lyrics of Scotland' (Glasgow 1870).

SCOTCH TERRIER. See DOG; TERRIER.

SCOTER, or SURF DUCK, a duck of the genus *Œdemia,* characterized by a broad short bill curiously swollen, bright-colored at the base of the upper mandible and with a hooked nail. These are the most marine of all ducks, though the American species may also occur about the Great Lakes, etc. They are comparatively weak

fliers but expert divers and feed chiefly upon mollusks and other animals, for which they dive and grope in the mud of shallow waters. The males of all the species are uniformly velvety black, with or without white markings on the head, and wings, and with bright colors on the bill. The females are plain brownish above, grayish below, with dull-colored bills. There are three common American species: the black scoter (*O. americana*), the white-winged scoter (*O. delandi*), and the surf duck or sea coot (*O. perspicillata*); and the European species occasionally wander into our territory. All of these species breed in the far north and winter within the United States as far south as New Jersey and Chesapeake Bay on the Atlantic and California on the Pacific side. A few may linger through the summer in Maine, etc.; and the second species is the most abundant. The females are soot-colored above and brownish-white beneath.

SCOTFORD, John Ryland, American clergyman and editor: b. Chicago, Illinois, Sept. 7, 1888. He was graduated at Dartmouth with the degree of Bachelor of Arts in 1911 and later studied at the Union Theological Seminary. In 1912 he was ordained to the Congregational ministry and thereafter was successively pastor at Kingfisher, Oklahoma, Junius Heights Church, in Dallas, Texas, the First Congregational Church at Waukegan, Illinois, and the Glenville Church of Cleveland, Ohio, until 1927. In 1928 he toured South America and from that year to 1931 he lectured and wrote much about the South American continent. From 1931–1942 he was editorial secretary of the Commission on Missions of the General Council of the Congregational and Christian Churches, and from 1943–1950 he was editor of *Advance*. He has written: *Mating Ministers and Churches* (1930); *Spanning a Continent* (1939); *Together We Build America* (1943); *The Church Beautiful* (1946).

SCOTIA, skō'shà, village, New York, in Schenectady County, altitude 240 feet; on the Mohawk River and the Barge Canal; on the Boston and Maine and the Fonda, Johnstown and Gloversville (motor coach) railroads; 3 miles north of Schenectady; served by Schenectady airport. It is a residential suburb. Settled in 1660, the village was incorporated in 1904; the government is by mayor and council. Pop. (1950) 7,812.

SCOTIA, skō'shĭ-à (Greek *skotia,* darkness), in architecture, a concave molding used especially in Classical architecture, as in the base of columns. The Greek skotia is so-called from the dark shadows cast by the sunken molding at the base of a pillar.

SCOTISM, the philosophical and theological system founded by Johannes Duns Scotus, toward the close of the 13th century and which in succeeding centuries was the greatest of the systems opposed to that of Thomas Aquinas. Scholastic philosophy was the philosophy of Aristotle interpreted, developed and reconciled with the Christian faith. In the latter part of the Middle Ages, scholastic theology, accepting the data of Catholic faith, occupied itself in arranging, defending and drawing deductions from them on the principles of scholastic philosophy. Of this scholastic philosophy and theology, there were two great schools, of which the Thomist found its home in the Dominican, the Scotist in the Franciscan, order. The Nominalist school found adherents in both of these orders and in the church generally, but never exercised an influence like that of the older systems, and really marks the decay of Scholasticism as a whole. The principles of Scotism are stated in the *Opus Oxoniense* and the commentary *The Four Books of the Sentences,* written by Scotus at Oxford. His whole philosophical and theological teaching is here in collected form. Scotists no less than Thomists were, in the strictest sense of the word, scholastics. The one as well as the other accepted the whole tradition of the Church as it was collected by Peter Lombard; to Scotus no less than to Saint Thomas the pope is the supreme guardian and divinely instituted exponent of the deposit of faith left to the church, the highest guide and ruler of the Christian commonwealth. Again Scotus, as well as Thomas, accepts Aristotle as the representative of human reason, the decisive authority in philosophical discussion. The Scotists were greater Realists than the Thomists. To the Thomists no universal exists as such. The essence is only actually found in the individual; it is by a process of the intellect—abstraction—that we separate humanity in general from humanity as it manifests itself in a particular man and reach the idea of man in general. To the Scotists the nature in all individuals of the same species was numerically one. The obvious difficulties of this theory led later Scotists to modify it till it was scarcely discernible from Thomism. The Scotists believed that in individuals there was a "Laeceitas," something which made them individual apart from matter; also "the created will is the total and immediate cause of its volition, so that God in respect thereto has no immediate but only mediate efficacy." The will is like a "free horse," grace like the rider, and the horse can throw its rider; otherwise, the will could not be free, and there would be no possibility of sin. Scotism denies the possibility of proving by reason the immortality of the soul; claims that the Word would have become man, even had there been no fall; that the merits of Christ were not infinite in themselves and from the union of his human nature with the Word, but only from the acceptation of them as infinite on the part of God. Consequently, the system denies the infinite value of the sacrifice of the Mass. The Scotist teaching in regard to the sacraments differed greatly from the Thomist position, admitting only a moral efficacy instead of the physical efficacy taught by the latter. Thomism denied the indifference of any deliberate action while the Scotists reject this reasoning, and hold that the end, and, therefore, the action, might be indifferent. The Scotist philosophy and theology are now abandoned but many of its opinions have been adopted. The Scotist opinion on the Immaculate Conception finally triumphed, and its theory on the Incarnation has recommended itself, as a philosophical view of that mystery, even to writers of note outside the church.

Consult *The Catholic Encyclopedia,* **vol. 13, New York (1912).**

SCOTISTS. See SCOTUS, JOHANNES DUNS; SCHOLASTICISM.

SCOTLAND, skŏt'lănd, **UNITED KINGDOM,** the northern division of the island of Great Britain, extending between lat. 54° 38′ and 58° 40′ 30″ N., and long. 1° 46′ and 6° 8′ 30″ W. It is separated from England substantially by the Solway, Cheviots and Tweed, the border isthmus being about 60 miles across; but the irregular boundary line, the historic Border-land measuring fully 100 miles. On all other sides it is bounded by the sea. The greatest length, from north-northeast to south-southwest, between Dunnet Head and the Mull of Galloway, is 287 miles. The breadth varies from 140 miles to less than 30, the latter in the north, between Dornoch Firth and Loch Broom. Few points in the mainland are more than 40 miles from the sea, the country being deeply penetrated by inlets. The country was formerly divided into a number of districts, many of the names of which are still familiar, such as Lothian, Tweeddale, Galloway, and Breadalbane; for political purposes, it is divided into counties. Scotland has an area of 30,533 square miles. The population was estimated to amount to 5,067,261 on 31 Dec. 1941. The capital is Edinburgh (pop., mid-1940 est., 475,500) and the largest city Glasgow (1,131,800); other large cities are Aberdeen (180,800), Dundee (179,000), Paisley (92,700), Greenock (78,948), Motherwell (64,708), and Clydebank (48,200). (For map see under Great Britain.)

Islands and Coasts.—The islands of Scotland are said to number altogether nearly 800. On the east coast they are few and small; but on the northeast are the two large groups, the Orkneys and Shetlands, the former numbering 52 islands, 28 permanently inhabited; the latter 100 islands, 29 inhabited; while on the west coast the islands are large and numerous. Here the Hebrides (q.v.) extend for 200 miles from the north to south, and are divided into the Inner and Outer Hebrides, the former lying close to the western coast of the mainland and stretching from Skye to Islay; the latter, parted from the Inner Hebrides by the straits of the Minch and the Little Minch, comprise the long chain of islands from Lewis to Benbecula. Enclosed in the Firth of Clyde are the islands of Arran, Bute and the Cumbraes, forming a county by themselves. The west coast of the mainland is generally a wild, deeply indented mountain-wall, presenting a series of inlets or sea lochs, while toward the middle the coast is cleft by two great inlets with openings to the southwest, the Firth of Lorn and its continuation Loch Linnhe, and the Firth of Clyde and its ramifications running far inland. The east coast is sometimes low and sandy, but is often formed by steep rocky cliffs of considerable elevation, the chief inlets being the Firths of Forth and Tay, and the Moray Firth, Cromarty Firth, etc.

Orography.—From the configuration and geological structure the country divides into three divisions, the Highlands, central Lowlands and southern Uplands. The first of these divisions lies north of a line stretching in a southwesterly direction from the coast of Kincardineshire to the Firth of Clyde; the third is the country south of a line drawn from Dunbar southwesterly to Girvan; the country between these lines forms the central Lowlands. The Highland division is remarkable for the number and elevation of its mountain-masses, many of the summits being over 4,000 feet high. The mountains best known by name are the Grampians, which form a system or series of masses covering a large area and culminating on the west coast in Ben Nevis, 4,406 feet high; while 55 miles to the northeast rises a remarkable cluster of summits reaching in Ben Macdhui the height of 4,296 feet. The Grampians and their connections are separated from the mountains farther to the north by Glenmore or the Great Glen of Scotland, a remarkable depression stretching quite across the country from sea to sea, and forming, by the series of lakes occupying it and the Caledonian Canal connecting them, a waterway from the west coast to the east. The southern Uplands are also essentially a mountainous region, summits of over 2,000 feet being frequent, though none exceed 3,000 feet above the sea. The central region, though much less elevated than the other two divisions, has none of the monotony usual in flat countries. Though occupying not more than a sixth of the whole surface, the fertility of the soil and its mineral treasures make this part by far the wealthiest and most populous. The present form of the land surface of Scotland is the effect of erosion or denudation. The country was at one time an elevated tableland, the upper surface of which is indicated by the summits of the mountain-masses, but has been deeply trenched and furrowed in all directions by the erosive action of water, ice and frost. The slope of the ancient plateau is determined by the direction of the principal river; in the northern part it is chiefly toward the east, in the southern more equally east and west.

Hydrography.—The chief rivers flowing east to the North Sea are the Tweed, Forth, Tay, South Esk, North Esk, Dee, Don, Deveron. Spey, Findhorn, etc.; those entering the sea on the west are the Clyde, Ayr, Doon, Dee, Nith, Annan and Esk. The Clyde in its lower course carries a vast traffic, this being rendered possible chiefly by dredging. Many of the rivers are valuable from the numbers of salmon they produce. A striking feature of the country is the great multitude of lakes varying in size from Loch Lomond (28 square miles) to the pool-like mountain tarns. In the northern Highlands almost every glen has its lake and every mountain hollow is filled by a stream or spring. Among the more noted are lochs Lomond, Katrine, Tay, Earn, Rannoch, Awe, Shiel, Laggan, Lochy, Ness, Maree, Shin, in the western and northern Highlands; Loch Leven, in the central Lowlands; and Saint Mary's Loch, lochs Ken, Dee and Doon in the southern Uplands.

Geology.—The older or palaeozoic rocks predominate almost everywhere in Scotland. The Highlands are composed almost entirely of crystalline schists, gneiss and quartzites; the central Lowlands of Old Red Sandstone, Carboniferous and Permian strata; the southern Uplands mostly of rocks of Silurian Age. In certain localities remains of secondary formations are represented over small spaces, while volcanic rocks cover considerable areas. Granite exists in great masses in many localities, and in some parts is extensively quarried. The most valuable mineral region is the central Lowlands, where coal and iron exist in such quantity as to make this one of the most important mineral fields of Great Britain

Population.—The census of 1801 showed the population numbered 1,608,420. Within 50 years it had increased to 2,888,742, and in 1901 it stood at 4,472,103. The population at the 1921 census was 4,882,497, but it dropped during the next decade by 39,517, the figure for 1931 being 4,842,980. Because of conditions prevailing during the Second World War, no census was taken in 1941, the succeeding decennial period. However, an estimate as of 31 Dec. 1941 placed the population at 5,067,261, though this figure excluded casualties among civilians and such factors as migration and the ingress of evacuees. Three quarters of the population was concentrated in one fifth of the area of the country, the seven counties out of 33 in Scotland which were most densely settled being Aberdeen, Angus, Ayr, Fife, Lanark, Midlothian, and Renfrew. (The county of Angus was known until 1928 as Forfarshire.) In 1942 births totaled 90,697 and deaths 64,963, this excess of births being at the rate of 5.1 per 1,000 of the population. During 1942 there were 47,514 marriages; this represented a rate of 9.5 per 1,000 of the population, as compared with an average of 6.9 during the decennial period 1921–30. "Gretna Green marriages," an irregular form consisting of simple declaration by the contracting parties, became illegal after 30 June 1940, a new form of civil marriage being instituted. Deaths in 1942 numbered 64,963, a rate of 13.0 per 1,000 as compared with 13.7 during 1921–30.

The counties of Scotland, their county seats, areas, and populations as estimated in mid-1940 are shown in the following table:

Counties and county seats	Area sq. mi.	Population mid-1940
Aberdeen (Aberdeen)	1,955	327,800
Angus (Forfar)	873	272,900
Argyll (Lochgilphead)	3,213	62,000
Ayr (Ayr)	1,128	298,700
Banff (Banff)	640	53,200
Berwick (Duns)	460	26,100
Bute (Rothesay)	217	16,300
Caithness (Wick)	685	25,700
Clackmannan (Clackmannan)	47	33,200
Dumbarton (Dumbarton)	241	158,800
Dumfries (Dumfries)	1,062	81,500
East Lothian (Haddington)	280	48,800
Fife (Cupar)	492	286,600
Inverness (Inverness)	4,088	81,100
Kincardine (Stonehaven)	383	25,800
Kinross (Kinross)	72	7,000
Kirkcudbright (Kirkcudbright)	897	30,200
Lanark (Lanark)	881	1,643,600
Midlothian (Edinburgh)	367	565,800
Moray (Elgin)	476	41,000
Nairn (Nairn)	195	8,300
Orkney (Kirkwall)	926	21,700
Peebles (Peebles)	554	14,100
Perth (Perth)	2,527	120,400
Renfrew (Paisley)	245	327,100
Ross and Cromarty (Dingwall)	3,078	61,900
Roxburgh (Jedburgh)	665	45,400
Selkirk (Selkirk)	257	21,900
Shetland (Lerwick)	550	19,700
Stirling (Stirling)	447	175,400
Sutherland (Dornoch)	2,027	15,200
West Lothian (Linlithgow)	120	83,900
Wigtown (Wigtown)	485	29,700
Total	30,533	5,030,800

Two fifths of the population (2,000,000) live in the four cities of Edinburgh, Glasgow, Dundee and Aberdeen; 26 towns with populations ranging from 92,000 to 15,000 contain nearly 1,000,000 between them; 66 medium towns (15,000-5,000) account for over 500,000; and the remainder live in villages or in the wide, open spaces of the Highlands and the southern Uplands.

Education.—Scotland has had a national system of elementary education for over two centuries, a school having been established in every parish by a law of 1696 (where such a school was not already established), according to a system proposed by John Knox long before. The Scottish Education Department, distinct from that of England and Wales, supervises the work of local education authorities in the counties and burghs. An advisory council assists the department, and teachers, parents, and other citizens constitute the local bodies. Legislation of 1918 and 1929 increased the powers of the central authority and made all primary and secondary education free; amending legislation enacted in 1936 permitted local education authorities to subsidize privately-owned nursery schools, and raised the school-leaving age from 14 to 15 with effect from 1 Sept. 1939. The imminence of war with Germany caused postponement of the latter step. Secondary education was given in "Junior Secondary" and "Senior Secondary" schools, the former for those leaving at 15, and the latter for those remaining a further three years. Children medically or mentally unfit were taught in special classes or institutions, and in some areas medical treatment, food and clothing were provided. Technical education was available in the secondary day schools, at Continuation (evening) Classes, at Junior Instruction Centers (for unemployed adolescents), and at Central Institutions, 12 in number, which functioned both by day and in the evening.

On 26 Oct. 1944, a bill was presented to Parliament applying to Scotland the government's policy for the development of education along the lines contemplated in England and Wales, and also making a number of other changes which affected only the Scottish system. Education in nursery schools and classes was, for the first time, to be made part of primary education. School-leaving age was to be 15 (as had already been provided in the act of 1936), and it was to be raised "as soon as practicable" to 16; traveling facilities were to be provided, as well as milk and meals in all schools; there were to be additional facilities for recreation, social and physical training, medical inspection (especially those suffering from a disability of mind or body); and employment likely to interfere with a child's education was to be prohibited or restricted. The bill also proposed the founding of "Junior Colleges" for the compulsory part-time education of young persons aged 15 to 18.

In addition to educational facilities provided in schools wholly financed by the government, there were also privately-conducted grammar schools and like institutions, most of which received financial assistance from the state and were subject to some measure of control and supervision. Adult education was fostered by the Scottish Education Department, the British Broadcasting Corporation and such private bodies as Labor Colleges and the Workers' Education Association.

The state made annual grants, too, to the Scottish universities, autonomous institutions which also derived income from the Carnegie Trust (half of its annual income of £100,000 being devoted to that purpose and half to assistance for needy pupils), from endowments, and from students' fees. About two thirds of the students came from the public elementary

schools and were in receipt of financial assistance. The first university was that of Saint Andrew, dating from 1411; next came that of Glasgow (1450), then Aberdeen University (1494) and lastly Edinburgh University (1582). The medical school at Edinburgh attracts students from all over the world. The Presbyterian and Roman Catholic churches maintain several theological colleges; and these and other denominations conduct colleges for training teachers for their own schools.

Religion.—Presbyterianism has larger support in Scotland than any other form of the Christian faith. The Church of Scotland (Presbyterian), which dates back to 1560, has frequently been disrupted by seceders. The Free Church and the United Presbyterian Church, each comprising groups of dissident church congregations, merged in 1900 to constitute the United Free Church, and the latter joined the Church of Scotland in 1929. Second largest religious body is the Roman Catholic Church, and others include the Episcopal Church in Scotland (adjunct of the Church of England), Baptists, Congregationalists, Methodists and Unitarians.

Local Government.—The Secretary of State for Scotland, the Lord Advocate, and the Solicitor General for Scotland represent the country in the British cabinet. The first-named heads the Scottish Office, in London, and, in Edinburgh, the Department of Agriculture, the Education Department, the Department of Health, and the Home Department. In 1929 local government in Scotland was reorganized drastically, bringing the system into conformity with that prevailing in England and Wales. County councils, and burghs having populations in excess of 20,000, became the principal local authorities, concerned, as a general rule, with administration of the poor law, health services, police forces, highway maintenance, and education; Edinburgh, Glasgow, Aberdeen, and Dundee, each termed a «county of a city,» remained responsible for educational matters within their confines, and those burghs which had their own police bodies at the time the 1929 law became effective continued to maintain them independently of the county councils. Nairn was combined with Moray, and Kinross with Perthshire, for administrative purposes, and thus, while there were 33 counties in Scotland, only 31 county councils functioned.

Finances.—While the Scottish fiscal system is in large part that of the United Kingdom, local authorities have considerable powers for raising revenue for local purposes. The two types of local taxes were termed "valuation" and "assessment," the equivalents of which in England and Wales, were, respectively, "assessment" and "rating." Local authorities could also raise loans for such purposes as the provision of airports, public bathhouses, cemeteries, electricity supply, gasworks, harbors, piers, docks, canals, markets, and local transportation services. The central government also made block grants to local authorities in Scotland for highway, health and like services, and, in addition, grants were made from the Ministry of Education for educational purposes, from the Ministry of Health for housing, and from the Home Office for police expenses.

Agriculture.—Through the 20 years immediately preceding the Second World War, the central government of the United Kingdom financed the purchase of many large estates and farms for subdivision among small farmers, who were also assisted with implements and stock. The result was that by the year 1939 nearly half of the 74,291 farms in Scotland were from five to 50 acres in extent, and less than 2,500 were larger than 300 acres. Oats are the principal cereal crop, and the only one available on the moist oceanic (western) border. Wheat and barley are grown mostly in the Lothians, Fife and the Merse of Berwick, and potatoes, turnips, swedes, and sugar beet are other crops of the east coast. Important fruit-growing districts are the Carse of Gowrie, and around Blairgowrie and Coupar-Angus. The mountain pastures of the southern Uplands and the lower hillsides in the Highlands support sheep. Notable breeds of cattle are the Ayrshire (a dairy breed), the Aberdeen-Angus (a black-polled beef stock), West Highlanders (also termed the Kyloe breed), and black-polled Galloway Shorthorns. Clydesdale is the originator of a famous breed of draft horses, and Shetland and Highland ponies are well known. Work on farms was made more attractive during 1937–38 when wage-rates were stabilized and vacations with pay guaranteed by law, and in 1939, with the prospect of a wartime curtailment of food imports into Great Britain, the government subsidized Scottish farmers in order to increase production and imported large stocks of agricultural machinery for them. During the Second World War, the acreage under crops in Scotland was vastly increased, the government assisting farmers with mechanized equipment and crews, and organizing the Women's Land Army, a conscripted force, to supplement farm labor.

Fisheries.—Both the freshwater and sea fisheries of Scotland are important, especially on the eastern coast. Aberdeen is the chief fishing center; others are Peterhead, Wick, and, on the west coast, Stornoway. The principal food fishes are herring, especially those of Loch Fyne; haddock, flat fish, notably Forth flounders, and cod. Fishing is also carried on for salmon, grilse, and sea trout. Considerable markets for Scottish herring exist in the countries of northwestern Europe.

Mining.—The mineral region of Scotland is the central Lowland. The largest coalfields were for long those in Lanarkshire, and others are in Ayrshire, Fife, the Lothians and Stirling. With exhaustion of the Lanarkshire coalfields already in sight, during the Second World War a new, rich field was being opened up to the southeast of Edinburgh, in what had been primarily an agricultural region. In common with a procedure adopted in England and Wales, during 1942 all coal deposits in Scotland were purchased from private owners by the government; companies owning mine-plant properties continued to operate them, henceforth paying royalties on coal produced to the government rather than to individuals. While operational and financial control was still retained by the operating companies, the government secured over-all control of production. With groups of coal mines placed under the actual management of experts responsible not to the mine operators but to the government, wage rates were increased, national minimum wages were established for the various types of mine workers, an output bonus was introduced, and permanent

machinery was set up both for negotiation and arbitration. Because of the critical shortage of manpower for the coal industry, during the Second World War, in Scotland, as elsewhere in the United Kingdom, men were drafted for work in the mines from December 1943, all new registrants for the armed forces becoming subject to a ballot for mine work.

The iron fields of Scotland lie near the coal, in the counties of Ayr, Lanark, Linlithgow, Renfrew, Fife, Midlothian, and Stirling. Three quarters of the oil shale is mined around Linlithgow, and the remainder in the vicinity of Edinburgh. Other important mineral products are the red and gray granite of Aberdeenshire; limestone is found principally in Fife and Midlothian; slate, chiefly in Argyll, some in Perth; lead and sandstone, in Lanark and Dumfries; fire clay, principally in Lanark and Stirling; and limestone, in Fife and Midlothian.

Manufactures.—The most important industries are those of metals and machinery, shipbuilding and textiles. Glasgow is the chief seat of all industries. After the First World War, the production of iron and steel in Scotland slumped as badly as it did in England and Wales, and recovery did not set in until 1937, when a large program for defense was initiated. The low-grade phosphoric ores had, for many years, been supplemented to a considerable extent by ores of high grade imported from abroad, and though considerable reorganization of manufacturing processes had been undertaken, by the time war once more occurred in 1939 some 30 per cent of all ore used in steel manufacture came from overseas. Belgium was the source of the sand employed in manufacture until war came, when Scottish sands were used perforce on a large scale. The virtual cessation of ship construction brought acute distress to many towns along the Clyde, within the Glasgow district and outside it, as well as in the shipyards on the east coast at Dundee, Fraserburgh, Peterhead, and elsewhere. Nevertheless, in the 1930's, largely with the aid of government subsidies, Clyde shipbuilders were enabled to construct the *Queen Mary,* the *Queen Elizabeth,* and other great liners. During the Second World War, Scottish yards (as, too, those in other parts of the United Kingdom) concentrated upon the building of warships and special types of merchant vessels, and upon repair to damaged shipping, leaving to the United States the execution of the vast program of mass-produced merchant vessels. However, Scottish yards adopted many American shipbuilding practices in the course of the war, in particular, extending rapidly the use of automatic welding machines, of pre-fabrication and of standardization.

The cotton industry centers chiefly in Glasgow and Paisley, the latter being known particularly for its threads; Aberdeen and Perth, among others, also have cotton mills, however. The woolen manufacture is settled in Stirling, Kilmarnock, Bannockburn, and Paisley, while the wool produced on the southern Uplands, combined with the presence of water as a motive-power, helped to locate the manufacture of woolen cloths in the towns of Hawick, Galashiels, and Selkirk, in the Tweed valley. Kilmarnock and Stirling are also important for their carpet manufactures, and Alloa for its woolen yarns. The linen industry, long carried on in Scotland, began at Glamis, in the county of Angus, in 1790; it has since remained in several towns of the county, including Dundee, which also specializes in jute, in Arbroath, Brechin and Forfar. Linens of the finest quality are produced in Dunfermline, and sewing threads are manufactured on a large scale at Paisley. After the First World War, the jute industry of Dundee greatly increased, and Kirkcaldy became the center of the linoleum industry in Scotland. The manufacture of silk, artificial silk, hosiery and lace are also of importance.

A special quality in the water assisted in developing paper manufacture in Midlothian during the 17th century, and subsequently the industry was extended to towns in the valley of the Esk, and to others in the vicinity of Edinburgh. The last-named ranks second only to London as a great printing center of the British Isles, and a considerable printing industry has also grown up in Glasgow. Chemicals are also made in Glasgow and neighboring towns, and sugar refineries are concentrated for the most part at Greenock, while Dundee is famous for its cakes and jams. The distilleries of Argyll, Banff, and Inverness produce the well-known Scotch whisky, while the best beers and ales come from the breweries of Alloa and Edinburgh. During the Second World War, the industrial workers of Scotland labored cheerfully for long periods with a total disregard of maximum hours and other limiting factors; their willingness is evidenced by the fact that in 1943, in all of Scotland, the time lost in trade disputes in every industry was less than one third of a day per worker in the year.

Early in 1942 the government set up a Scottish Council on Industry, representing local authorities, chambers of commerce, organized workers, and financial institutions, to plan the country's postwar industrial development. Numerous committees were created to consider such projects as light engineering, canning, transportation, the white fish and plastics industries the manufacture of fine chemicals and house fittings, and the crofter woolen industry. Through the efforts of this body, by the middle of 1944, with the war still in progress in Europe, some 500 new manufacturing plants were in production, the buildings and necessary equipment costing about £11,000,000. As a further incentive to establishment of new industries in the Highlands, a scheme to harness the water-power resources at a total cost of £6,000,000 was authorized under the Hydro-Electric Development Act of 1943. By March 1944, 102 hydroelectric projects had been approved for Perthshire, Dumbartonshire, Argyllshire and Inverness-shire having a potential annual output of 6,274 million units of power; one power-station, to generate 100,000,000 units a year, was to be located on Loch Lomond, between Ardlui and Tarbet, and Loch Sloy was to have Scotland's biggest dam (1,200 feet long and 150 feet high).

Overseas Trade.—Although a large proportion of goods consumed in Scotland are now brought into the country by rail from England, the indented coasts, and deep, inrunning estuaries, greatly favored the past development of Scottish commerce, and much of it still sails directly into and from the fine ports. The western ports trade chiefly with the Americas, the west of England and Ireland; the eastern ports with northwestern Europe. Into the ports of the Clyde are brought bacon, ham, grain, flour,

tobacco, livestock, leather, lard, timber, and iron ore. Representing foreign imports in the eastern parts are butter, grain, flour, eggs, linen, yarn, and timber. The exports in either case are almost identical in character with British exports generally. Glasgow is by far the busiest port. In volume of trade it is followed by Greenock and Leith; and other leading ports are Aberdeen, Ardrossan, Ayr, Burntisland, Dundee, Grangemouth, and Methil.

Communications.—Railroad lines reach Edinburgh and Glasgow from the south by skirting round the southern Uplands through the eastern edge of the plain, and, by means of river valleys, penetrating the heart of the southern Uplands themselves, while the flat country between Edinburgh and Glasgow made railroad construction easy. Northward, connection from Glasgow and Edinburgh is provided by the North British system (since 1921 part of the London and North Eastern Railway), which crosses the rivers Forth and Tay by two magnificent bridges, and runs along the flat coastal sill to Aberdeen; thence the Great Northern of Scotland (also merged into the London and North Eastern Railway) carries it on to Elgin and to Inverness. In 1921 the London, Midland and Scottish Railway absorbed the Caledonian, another route north which enters Strathmore through the gap between the Campsie Falls and Ochils, and continues through Perth and Forfar to the coast at Montrose, whence it runs on to Aberdeen. The Highland line (likewise taken into the system of the London, Midland and Scottish Railway in the same year) penetrates from Perth up the valley of the Tay and of the Garry to Inverness, whence it continues north to Wick and Thurso. Canals in Scotland, having a combined length of 184 miles, number three. The Caledonian connects the nearly continuous line of lochs which fill Glenmore, and is used principally for tourist traffic, as is the Crinan Canal across the peninsula of Kantyre; they are national property. A deep depression secured the construction in 1790 of the Forth and Clyde Canal, between Bowling and Grangemouth; it passed into railroad ownership, and eventually was acquired by the London and North Eastern Railway. Highways in Scotland have a total length of 25,873 miles. The main routes ("trunk roads"), 1,188 miles in length, are maintained and improved at the cost of the central government; county roads (21,898 miles) are similarly maintained by the county councils; and the remainder are the responsibility of the burghs. Scotland became of considerable importance in transoceanic aviation during the Second World War. From the airport near Prestwick a scheduled service to Stockholm, Sweden, was inaugurated, and it was in constant use by planes crossing the Atlantic to North America.

Scotland in the Second World War.—The Scottish people supported the war effort with a zeal that was not anywhere excelled. Farmers vastly increased the acreage under the plough, shipyards and manufacturing plants went into maximum production (largely with the aid of unskilled workers and women), and the accomplishments of Scottish regiments on the fighting fronts were watched with national pride. Scotland provided a haven, too, for children evacuated from danger zones in England, while Norwegian, Polish and other troops from countries overrun by the Germans found on Scottish soil the facilities to reorganize and retrain in order to meet the enemy once more.

Scotland suffered, too, from the attacks of the enemy. The Firth of Forth, not the Thames estuary, was the first part of Britain to experience enemy attack from the air, the cruisers *Edinburgh* and *Southampton,* lying near the Forth Bridge, being bombed on 16 Oct. 1939. On the following day the first bomb to fall on British soil exploded at Hoy during an attack on nearby Scapa Flow, the great naval base at that period sheltering the Grand Fleet. The first civilian was killed at Bridge of Waith, in the Orkneys, on 16 March 1940; and on 10 April the first bomb on the mainland of Britain for 22 years (since the First World War) fell near Wick. On 12 July 1940, following the surrender of France, Aberdeen, which became Scotland's most frequently raided city, had its first damaging raid when a single plane dropped 20 bombs which killed 34 people. Glasgow had its first attack on 19 July; the city and surrounding area were raided four times on 18 September, when the Battle of Britain was at its height; and bombs were dropped in many areas of Scotland during the night of 23–24 October.

However, Scotland endured its heaviest attacks during the spring of 1941. Through the nights of 13–14 and 14–15 March, for some eight hours at a stretch, the docks and shipyards along the Clyde, and particularly at Clydebank, were bombed and burned; only 12 of Clydebank's 12,000 houses escaped damage, and all but 2,000 of the wartime population of 55,000 had to leave the town. Clydeside's second big raid occurred on the nights of 5–6 and 6–7 May, Paisley and Greenock being the chief sufferers. Enemy aerial attacks on Scotland dropped sharply from mid-May 1941. During the first seven months of 1942 there were 20 attacks on the country, the majority on the northeast coast. Altogether Aberdeen was raided on 32 occasions, and Peterhead and Fraserburgh each 23 times, earning for them the unenviable title of Scotland's front-line towns. There were no attacks from August 1942 to February 1943; and there were only four raids thereafter down to the close of 1944. A total of 6,600 high explosive bombs and 300 parachute mines were dropped in Scotland. The total killed (or missing, believed killed) was 2,298, those injured and detained in hospitals numbered 2,167, and 3,558 were slightly injured.

Civil History.—The country now called Scotland emerges from prehistoric obscurity during the Roman occupation of Britain, though for many centuries little is known of its history. It is supposed that the earliest inhabitants of the country were a non-Aryan race resembling the Iberians, and typified now by the Basques. A Celtic (and Aryan) people seem subsequently to have entered the country, and to have gained predominance over the non-Aryans, the combined people occupying at the Roman invasion most of the country north of the Forth and Clyde estuaries, which was called Caledonia (q.v.) by the Romans, and its people Caledonians. The southern part of the country was inhabited by another Celtic race, the Brythons or Britons, of the same blood as the Welsh. The descendants of the Caledonians were afterward called Picts, and were the predominant people in North Britain at the begin-

ning of the 6th century, when a colony of Scots or Dalriads from Ireland effected a settlement in Argyll, and gradually spread over the adjacent regions. It is from these Scots (a Celtic and Gaelic-speaking people) that the country afterward received the name of Scotland, the original Scotland (Scotia) being Ireland. The Pictish tribes were divided into two great sections, the Piccardach or Southern Picts, and the Cruithne or Northern Picts. In the 9th century the Dalriadic Scots with the help of the Cruithne conquered the Southern Picts, but the Northern Picts, the ancestors of the modern Highlanders, still retained their independence. The Teutonic element was introduced into Scotland as early as the 4th century, when bands from North Germany seem to have formed settlements on the east coast south of the Firth of Forth; and this part of the country was subsequently united to the Anglian kingdom of Northumbria, which extended from the Forth to the Humber. To the west of this kingdom, from Dumbarton to the Solway and into England, extended the kingdom of Strathclyde or Cumbria, inhabited by Romanized Britons.

About the middle of the 9th century Kenneth MacAlpin, son of a ruler of a body of Scots established in Galloway, but of Pictish descent through his mother, united in his own person the sovereignty of both the Picts and the Scots. The Norsemen had already established a footing on the islands of the north and west coasts as far south as the Isle of Man, and a Norse earldom of Orkney was established. Kenneth's kingdom comprised Central Scotland (Argyle, Perth, Angus, Mearns and Fife), with Scone as capital, the north of Scotland being mostly under independent chiefs, or mormaors. The reigns of Kenneth and his immediate successors, Donald I, Constantine I, Grig, Donald II, Constantine II, Malcolm I, Kenneth II, Malcolm II, Duncan, and Macbeth, were one continued warfare with the Norsemen on one hand and with the Britons of Strathclyde and the English of Northumbria on the other. Malcolm I (943–954) obtained Cumbria (Strathclyde) as a territorial fief from Edmund I, and in 1018 his grandson, Edmund II, secured Lothian, hitherto part of Northumbria, two events which materially influenced the after history of Scotland.

On the advent of Malcolm Canmore (1058) to the throne after the death of Macbeth, the able usurper and murderer of Duncan (see MACBETH), the purely Celtic monarchy came to an end.

The conquest of England by William of Normandy, the usurpation of the English throne by Stephen, and various other incidents of English history embroiled Scotland. Sir William Wallace (q.v.) distinguished himself in disputing the claim of Edward I to the throne of Scotland and Robert Bruce securing the independence of the country and his title to the throne by the decisive battle of Bannockburn in 1314. He was succeeded by his nephew, Robert Stewart, and he by his eldest son, Robert. He being a weak prince, the reins of government were seized by the duke of Albany, who starved to death the eldest son of the king. James, the second son, to escape a similar fate, fled to France; in the year 1424 he returned to Scotland, and having excited the jealousy of the nobility, he was assassinated in a monastery near Perth. James II, his son, an infant prince, succeeded him in 1437. He was killed by the bursting of a cannon at the siege of the castle of Roxburgh. James III ascended the throne at the age of seven years. His reign was weak and inglorious, and he was murdered in the house of a miller, whither he had fled for protection. James IV, a generous and brave prince, began his reign in 1488. He was slain at the battle of Flodden. James V, an infant of less than two years of age, succeeded to the Crown. He died in 1542, and was succeeded by his daughter, the celebrated Queen Mary, whose history and tragical end are well known (see MARY STUART). She was succeeded by her son James, who, in 1603, ascended the throne of England, vacant by the death of Queen Elizabeth, when the two kingdoms were united into one great monarchy which was legislatively united in 1707. A joint commission was appointed to draw up articles of union in 1706. The Scottish Parliament met to consider the articles, which encountered a strong opposition headed by the duke of Hamilton, and strongly backed up by the bulk of the people. A majority of the Parliament, however, carried the measure, 16 Jan. 1707; it received the royal assent 4 March; and the Union took effect 1 May. The chief provisions of the Act of Union were (1) that the two kingdoms should be united under the name of "Great Britain"; (2) that the succession to the crown of the United Kingdom should be the Electress Sophia of Hanover and her heirs, being Protestants; (3) that 16 Scottish peers and 45 Scottish members of the House of Commons should be elected to the one Parliament sitting in London; (4) that the Established Presbyterian Church of Scotland should be maintained; (5) that Scotland should keep unchanged her own laws and customs relating to property and private rights, and also the Court of Session and other Scottish courts; (6) that all the rights of trade, free intercourse and citizenship should be the same for Scottish and English subjects. Henceforth the general history of Scotland may be said to be almost entirely identified with that of England.

SCOTTISH LANGUAGE AND LITERATURE

Language.—The history of the language spoken in the country we now call Scotland does not coincide with the development of any single "Scottish" language. It took a long time for the Gaelic and non-Gaelic elements to combine to form a single Scottish nation, and until this development took place—it almost took place in the 15th century, but a succession of unfortunate events postponed it until the 18th—there were at least two languages existing side by side, each with a claim to be the true language of Scotland.

The original "Scots," who came from Ireland to the west of Scotland about the end of the 5th century, gave their name to the kingdom of Scotia, which, in the 9th century, absorbed the earlier kingdom of Pictavia, with the result that the Picts soon adopted the Gaelic language of the Scots. Thus the inhabitants of the north and west of Scotland were speaking a common Gaelic tongue by the 11th century, if not earlier. During the succeeding centuries, the non-Gaelic speech of Lowland Scotland pushed north and west, until today Gaelic is spoken only by a small fraction of the Scottish people. In 1931, those who spoke only Gaelic numbered 7,069, while 130,080 persons spoke both Gaelic and English.

The language and literature of the Gaelic Scot remained closely associated with Irish culture until the emergence of a more purely Scottish Gaelic literature after the Reformation severed the ties with Ireland. The new native Gaelic tradition came to its climax with the 18th century Scottish Gaelic poets, but the rapid decline of Gaelic as a spoken language in Scotland (a decline hastened by the unhappy fate of the Highlands after the defeat of the Jacobite Rebellion in 1746) drastically restricted the audience for such poetry and helped to produce in the minds of both Englishmen and Scotsmen the impression that Scottish literature was identical with the non-Gaelic literature of Lowland Scotland. It is that non-Gaelic literature to which, for reasons of space, the present discussion is confined. (See also CELTIC LANGUAGES, CELTIC LITERATURE, CELTIC RENAISSANCE, GAELIC LITERATURE, and SCOTTISH GAELIC LITERATURE.)

Lowland Scots is a northern form of English, and is directly descended from the old Anglian speech. The northern English dialect originally spread into Scotland from Northumbria, steadily ousting the various Celtic dialects (the Gaelic of the Scots and the Brythonic Celtic of much of the Lowlands and the southwest) as it pushed northward. In the east, where there were no mountain barriers, the Anglian speech pushed far north, up to Aberdeen and beyond to the Moray Firth. It was this original Anglian speech that developed into the distinctively "Scots" form of the English language which has been known in modern times simply as "Scots."

Such literature as existed in the Old Anglian speech has hardly survived the Danish destruction of the Northumbrian monasteries and other repositories of manuscripts. However, a few fragments remain, and these make clear that in its early phases the language of Lowland Scotland was (at least in its literary form) substantially identical with that of northern England. The fragment of the *Dream of the Rood* carved in runes on the Ruthwell Cross in southwest Scotland, dating probably from the 9th century, is in a language that might have been written equally in the Lothians or in Yorkshire, while John Barbour's *Brus,* written in Aberdeen in the late 14th century, is, so far as linguistic criteria are concerned, hardly distinguishable from contemporary work produced anywhere in England north of the Humber.

Early Scots is thus identical with the language spoken and written in northern England as far down as the Humber, and linguistically its history is that of the Northumbrian dialect of Old and early Middle English. However, the stabilization of the Scottish border, and the growing sense of separation from England which the Wars of Independence in the late 13th and early 14th century produced, helped to keep the language of Scotland away from the influences which were leading to the standardization of literary English as the South East Midland dialect. As a result, the English spoken and written in Scotland retained its northern characteristics long after such characteristics had disappeared from the written language of northern England. The growing sense of nationality produced by the Wars of Independence and later by the rule of the early Stuarts (Stewarts) encouraged Lowland Scotland to consider itself culturally Scottish rather than English, and by the middle of the 15th century, at which time the South East Midland dialect had become more or less standard in England, it is justifiable to talk of "Scots" as a separate, purely Scottish, form of literary English. Gaelic, Norse, French, and direct Latin influences and importations further helped to differentiate Scots.

It was not until the 16th century that we find the term "Scots" used in its modern sense, i.e., to denote the language of non-Gaelic Scotland. Until that time, we find "Scottis" used to designate the speech of the Gaelic-speaking Scots to

the north and west, and "Inglis" used for the language of Lowland Scots. The modern use of "English" to denote standard English, "Scots" to denote the northern form of English which became distinctively Scottish by the middle of the 15th century, and "Gaelic" (in the 16th century called "Ersch" or "Yrische") for the Celtic language of the north and west, is a development which began in the course of the 16th century.

The political history of Scotland after 1603 is largely responsible for the fact that Scots, in the modern sense of the term, gave way to English as the literary language of the Scottish nation. The Reformation deprived Scotland of her traditional French alliance and brought her into close cultural contact with England. John Knox's *History of the Reformation* (published in 1584), a work whose language shows a strong Southern influence, is an interesting sign of the times. The fact that Presbyterian Scotland used an English and not a Scots version of the Bible was one of the decisive factors, and the far-reaching consequences of the union of the crowns in 1603, which brought the Scottish court to London, and the union of parliaments in 1707, are not easily overestimated. The great revival of literary Lowland Scots in the 18th century, culminating in the work of Robert Burns, began as an antiquarian compensation for political defeat, and ended in a magnificent flowering of Scottish poetry, which, nevertheless, came too late to change the course of historical developments. Modern attempts to revive Scots as a literary language, and to emancipate it from the sentimental exhibitionism to which it was confined in the middle and later 19th century, have been made by several crusading writers, notably Hugh MacDiarmid (Christopher Murray Grieve), but so far these efforts have not been effective on a really national scale.

Literature.—There is little surviving material for a history of non-Gaelic Scottish literature dating from before the 14th century. The earliest extant piece of Scottish poetry is an anonymous stanza, preserved in Andrew of Wyntoun's *Oryginale Cronykil* (c.1420), lamenting the death of King Alexander III (1286). The names of many popular songs which may well date from before 1300 are preserved in later works, and suggest the existence of a lively song tradition, which, like so much Scottish literature, did not survive the Middle Ages. The name of Thomas of Erceldoune, called Thomas the Rhymer (q.v.), who must have lived in the latter half of the 13th century, has survived in a legendary fashion, but none of his works remain. We do know, however, that he contributed to the Arthurian cycle. Scotland's contribution to medieval romance seems to have been much greater than the number of surviving works would indicate. The mysterious Hucheone (Huchoun) of the Awle Ryale (fl. 14th century), whose true identity has long been a matter of dispute, has been identified by some with the author of *Sir Gawaine and the Green Knight*—one of the most individual of Arthurian romances—and of the remarkable allegorical lament, *The Pearl* (both c.1370, qq.v.). Hucheone, if he really was the author of all the works that have been at one time or another attributed to him, was not only the greatest Scots poet of his century, but one of the greatest poets in medieval Britain.

A clearer figure is Hucheone's contemporary, John Barbour (1316?–1395, q.v.), archdeacon of Aberdeen, whose *Brus* (completed in 1375) is versified history of a very high order. It is an account of the campaigns of the Scottish patriot king, Robert the Bruce, whose great victory over the English Army at Bannockburn in 1314 marked the victorious end of the Scottish Wars of Independence. Barbour was in touch with people who had known Bruce, and his poem is in large measure genuine history. The narrative, in octosyllabic couplets, is vigorous and lively. The *Oryginale Cronykil of Scotland,* written early in the 15th century by Andrew of Wyntoun (1350?–?1420, q.v.), is another Scottish verse history, more conventional in tone and more ambitious in scope than the *Brus.* Like most medieval histories, it starts with the creation, but it is an important source when dealing with periods of history close to the author's own time.

Later in the 15th century the writer known to tradition as Blind Harry (Henry the Minstrel, fl. 1470–1492) produced his *Actis and Deidis of the Illustere and Vailzeand Campioun Schir William Wallace,* a free, romantic version of the life of the great Scottish patriot who preceded Bruce in the long struggle against Edward I of England and his son. A facile and rather flamboyant poetic narrative, written for the most part in heroic couplets (though there are lyrical interludes in other metres), it appeals more forcefully to the Scottish popular imagination than the more sober work of Barbour, and long remained popular. It is full of graphic and picturesque scenes, and what it lacks in historical accuracy it certainly makes up in vividness. An early 18th century "modernisation" (1722) by Hamilton of Gilbertfield was widely read for many years.

The Scottish Chaucerians.—Blind Harry's *Wallace* seems to have been influenced in some degree by the great English poet, Geoffrey Chaucer (1340?–1400, q.v.), whose fame spread rapidly throughout Lowland Scotland and whose influence in 15th and 16th century Scottish poetry is indicated by the title "Scottish Chaucerians," long used for those poets whose work constitutes the fine flower of Scottish medieval literature. This title is perhaps somewhat misleading, for these writers are by no means mere imitators, and have many wholly original qualities. William Dunbar, for example, shows qualities of mind and types of skill far removed from anything in Chaucer or his English imitators. But the title is justified in some degree, as Chaucer's work was undoubtedly a major influence and source of inspiration in Scotland for over a century after his death.

James I.—The Kingis Quair (1423), generally ascribed to King James I of Scotland (1394–1437, q.v.), opens what is perhaps the greatest century in Scottish literary history. This work is a remarkable narrative poem in the love-allegory convention, but with a delicacy of expression and a tenderness of personal feeling which distinguish it from other examples of this form. Written in Chaucer's 7-line stanza, in a Scots considerably modified by Chaucer's English, *The Kingis Quair* is the record of James's love for and courtship of Lady Jane Beaufort, whom he met during his long imprisonment in England and eventually married.

Henryson.—With Robert Henryson (1430?–?1506), we come to the first Scottish poet to approach Chaucer in sustained achievement.

Henryson's chief work, *The Testament of Cresseid* (a sequel to Chaucer's *Troilus and Criseyde*), is a brilliant narrative poem done with a quiet wisdom, a realistic precision of imagery, and a genuine sense of the dramatic, which make it one of the masterpieces of Scottish literature. Henryson was the first medieval narrative poet to emancipate himself completely from the Italianate imagery which dominates even the landscapes of Chaucer. His intimate and vivid images drawn from contemporary Scottish life, and in particular his strong sense of contrast between a warm domestic interior and the chill landscape of a Scottish winter, founded a tradition in Scottish writing that was revived by Burns and exists even to the present day. Similar qualities are shown in his *Morall Fabilles of Esope,* in which the classical tales are given a strong Scottish flavor, with much local color and quiet humor. *Robene and Makyne,* a terse pastoral *débat* done with epigrammatic force, is a perfect thing of its kind; *Orpheus and Eurydice,* a retelling of the classical story whose conventionality of manner is relieved by the brilliant lyrical "complaint" in the midst of the poem; and *The Bludy Serk,* a brief but powerful allegorical tale—add further to the stature of this shrewd, humorous and gentle poet.

Dunbar.—The third of the so-called "Scottish Chaucerians," and probably the greatest, is William Dunbar (1460?–?1520, q.v.), whose versatility and technical virtuosity represent something unprecedented in Scottish poetry. A poet of the court of James IV, during whose reign Scottish civilization attained a short-lived, feverish brilliance which is reflected in Dunbar's poetry, he produced work in almost every known medieval tradition, and also wrote numerous personal and "occasional" poems unlike anything else in the Middle Ages. In *The Thrissil and the Rois* (1503), he gave an allegorical account of the marriage of James IV and Margaret Tudor which is remarkable for sustained richness of imagery, metrical virtuosity, and vivid descriptive power. More individual are his realistic and humorous pictures of court life, presented with tremendous verve and gusto. His descriptions of Edinburgh town life, with their impressive gray-and-silver imagery and metrical diversity, are equally notable; while his religious poems, with their resounding Latinized vocabulary ("aureation") reflect the spirit of medieval Edinburgh. He could be religious, comic, obscene, autobiographical, descriptive, and strictly conventional by turns, and occasionally he let himself go (as in *The Dance of the Sevin Deidly Synnis,* written between 1503 and 1508) with a furious serio-comic abandon which takes the reader by storm. *The Tua Mariit Wemen and the Wedo,* written in the old alliterative convention, is a dialogue done with vivid ironical humor, reminiscent of much 20th century satire in its unsparing exposures, and at the same time essentially comic. This is the longest of Dunbar's poems, which are usually short and in stanza form. In touch with all the literary conventions of medieval Europe, Dunbar was at the same time an autobiographer, a realist, and a true disciple of those wandering scholars of an earlier age who founded the goliardic tradition which, except for Dunbar, hardly survived after the 15th century save in oral and popular forms. Finally, Dunbar was a technical virtuoso and a poetic craftsman of remarkable quality.

Also belonging to the 15th century are the lively romance *Raif Coilyear* (a Charlemagne romance in a Scottish setting by an anonymous author of the third quarter of the 15th century); and two remarkable poetic accounts of rustic revelry, *Peeblis to the Play* and *Christ's Kirk on the Green,* both rollicking descriptions of popular merrymaking, written in a distinctive stanza form which has been much imitated in later Scottish literature. These two poems, combining the folk and the "art" tradition in Scottish song, were often reprinted in the 18th century and greatly influenced the work of both Fergusson and Burns.

Douglas.—The last major poet in the "Scottish Chaucerian" tradition is Gawin Douglas (1474?–1522, q.v.), whose allegorical poems, *The Pallice of Honour,* and *King Hart,* are the most complete examples in Scottish literature of the medieval allegory. They are labored, artificial, and very consciously traditional both in form and subject matter, and do not bear too easily their load of Christian and classical learning. These poems often reach a high level of sonorous eloquence, but they lack the vitality of Dunbar, even at his most aureate. Douglas' greatest achievement is his translation of the *Aeneid,* the first verse translation of that poem in Britain. It is done in couplets with sustained vigor and a noteworthy clarity of imagery, but the poetry is hardly Virgilian in style or timbre. The most remarkable parts of the work are the prologues to the individual books, in which Douglas gives descriptions of the Scottish countryside infused with a personal emotion in a manner unprecedented in English or Scottish literature at that time.

16th and 17th Centuries.—With Sir David Lindsay, or Lyndsay (1490?–?1555) we come to a real break with the medieval tradition, in spite of his allegorical poem *The Dreme* (1528), with its medieval properties, and many other medieval echoes throughout his work. Lindsay was primarily a satirist who castigated the evils of his time with a coarse vigor. In *The Testament and Complaynt of our Soverane Lordes Papyngo* (1530), he satirizes the abuses in the church and at court with an almost personal bitterness. His *Satyre of the Thrie Estaitis* (1540, the only extant Scottish morality play) is of considerable historical interest, as it approximates to the form of the modern drama more closely than anything that had yet been written in England. An adaption of the morality play for purposes of political, social and ecclesiastical satire, it is written in a variety of metres, with great spirit and considerable humor, though at inordinate length. *The Historie of Squyer Meldrum,* in fast-moving octosyllabic couplets, is a picaresque narrative, with sufficient lively passages to hold the reader's interest, but lacking in any profounder qualities. *The Monarchie* (1554), Lindsay's longest work, is a rather dull dialogue between Experience and a Courtier concerning the state of the world, together with a history of man from the creation to the judgment day. Lindsay is a traditional poet, perhaps more important historically than intrinsically.

Sir Richard Maitland of Lethington (1496–1586), is more impressive as a collector of older Scottish poetry than as a poet in his own right, though his original work is both dexterous and varied.

The Reformation in Scotland destroyed many

traces of earlier literature, and in addition brought about social and political conditions under which the development of the native Lowland Scots literary tradition became, for the time being at least, impossible. Thus at the time when Lowland Scots literature promised most—after the molding of a Scottish literary tongue by the great poets of the 15th and early 16th centuries—it was wiped out almost entirely. The accomplished love lyrics of Alexander Scott (1525?–?1584), and the poems of the more versatile though less brilliant, Alexander Montgomerie (1556?–?1610), represent a temporary revival which has been attributed to the influence of the Pléiade in France. Montgomerie's *The Cherry and the Slae* (1597), and *The Bankis of Helicon,* are curious allegorical poems in an interesting 14-line stanza which was later imitated by Burns. By this time, the new experimentation in English verse forms that had already manifested itself in England in such works as *Tottel's Miscellany* (1557) was spreading to Scotland, though the state of the country did not allow the literary Renaissance which it produced in England to develop in the north. And Scottish drama, which began so promisingly, was completely suppressed.

Among the minor writers of this period must be mentioned Mark Alexander Boyd (1563–1601), who wrote excellent Latin verse and one brilliant sonnet in Scots, and Alexander Hume (1557?–1609), whose *Hvmnes or Sacred Songs* (1599) are less interesting than his admirable long poem descriptive of a summer's day from dawn to dusk, *Of the Day Estivall.* Sir Robert Sempill (or Semple) of Beltrees (1595?–?1668) remains famous for his single masterpiece, *The Life and Death of the Piper of Kilbarchan* (otherwise known as the *Epitaph on Habbie Simson*), which was the model for innumerable later Scottish poems in the same style and meter, including several by Ramsay, Fergusson and Burns. The stanza, used in Burns' *To a Mouse* and other poems, was already accepted in the early 18th century as peculiarly suited to Lowland Scots poetry.

An interesting sign of the times is the *Gude and Godlie Ballatis* (the first known edition of which belongs to 1567, although there were probably earlier editions), a product of the Scottish Reformation. This collection of Protestant verses is divided into four sections: a catechism of doctrine, in prose and verse; 16 *Spiritual Sangis; Certaine Ballatis of the Scripture;* and *The Psalmes of David, with uther new Pleasand Ballatis.* The final section is the most interesting, and includes a great variety of verse, from genuine religious poetry and scriptural paraphrases to parodies of popular songs in which a religious meaning is introduced. This collection, probably the work of James (q.v.), John, and Robert Wedderburn, was very popular in the late 16th and early 17th centuries, but after the victory of Calvinist doctrine over other forms of Protestant theology, in the 17th century, the book (whose doctrine was strongly Lutheran) soon lost favor.

During the period of turmoil and confusion which reigned in Scotland in the latter part of the 16th and during much of the 17th century, any literary tradition is difficult to trace, and all one can do is pick out names here and there. On the whole, the 17th century was a sterile one as far as literature is concerned, except for folk poetry, which flourished beneath the surface and became all the richer, as it was almost the sole literary expression of the nation at this time. Scottish folk songs do not survive in any great number from before the latter part of the 16th century, but from this period and throughout the following century the surviving specimens are numerous and varied, and often of the highest quality. And then there are the ballads (q.v.), so much more numerous and remarkable in Scotland than in England.

Medieval Scottish prose is largely written in Latin. The 16th century produced some excellent translations and also the outstanding early prose work in Scots, *The Complaynt of Scotland* (1549), largely an adaptation of *Le Quadrilogue Invectif* (1422), by the French writer, Alain Chartier. The language of this anonymous work is a highly ornate Scots; and the subject is an allegorical presentation of the case against an English alliance and for the traditional ties with France. Inserted in the poem is a *Monolog Recreative,* which contains a most interesting list of popular songs, stories, and dances, the majority of which are not extant, thus providing an important source for Scottish literary history. The Reformation brought endless works of literary controversy, which can hardly be classed as literature. The *Historie of the Reformation in Scotland,* begun in 1559 by John Knox (1505–1572, q.v.), is a work whose chief literary significance lies in the encroachment of English forms on its Scottish diction.

The union of the crowns in 1603 hastened the decay of the Scottish literary language. William Drummond of Hawthornden (1585–1649, q.v.) wrote in the standard literary English of his day, with an eye on the Italians and the Elizabethans. He is on the fringe of the Elizabethan English tradition rather than at the center of a Scottish one. Gradually Lowland Scotland developed a split personality—thinking and talking in Scots, and writing in English—which was unified only in individual cases and in exceptional circumstances. The Scots speech itself began to break up into a series of dialects (q.v.) thus becoming less suitable as the language of a great literature. With the union of the parliaments in 1707, it looked as though the complete Anglicization of Scottish culture was inevitable.

18th Century Revival.—But this did not take place. After the political union with England, Lowland Scotland began to rediscover its nationality, and the immediate result was the development of a native antiquarian movement whose first important manifestation had already occurred the year before the union, in 1706, when James Watson (d.1722) of Edinburgh published the first volume of *A Choice Collection of Comic and Serious Scots Poems both Ancient and Modern.* This was a deliberate attempt to revive interest in what Watson called "our own native Scots dialect" and the poetry that had been written in it. The collection represented a turning back to the roots of Scottish culture, to the period when Scottish literature was still both Scottish and literature, and to the folk tradition which alone was able to survive the 17th century. Watson thus began a movement for collecting and reprinting older Scottish literature—both folk literature and "art" literature—which in turn produced both a creative and an antiquarian movement in Scotland.

Ramsay.—Allan Ramsay (1686–1758, q.v.), whose activities as bookseller, antiquarian, poet,

and patron of the drama achieved much for Scottish literature, was largely instrumental in bringing social and literary life closer together, and is thus indirectly responsible for that host of clubs, societies, literary associations and similar organizations which made later 18th century Edinburgh so distinguished for its unique combination of literature, conversation and drink. Ramsay's *Tea-Table Miscellany* (first volume, 1724) was a mixed collection of old and new songs and ballads by authors living and dead, and included many hitherto unprinted specimens of Scottish folk literature.

Fergusson.—The revived Scots tradition was carried to new heights by Robert Fergusson (1750–1774, q.v.), whose brief career produced a group of brilliant Scots poems unsurpassed even by Burns for their liveliness, humor and vivid pictorial quality. Fergusson was in touch both with the medieval Scottish tradition, and with the folk tradition that survived longer, and also—very actively—with contemporary "low life," and with student traditions which preserved the old goliardic moods.

Burns.—Robert Burns (1759–1796, q.v.), the Ayrshire farmer whose work was more than touched by the sentimental views of the Scottish novelist, Henry Mackenzie (1745–1831, q.v.), managed however to maintain and progressively strengthen his contact with the local folk traditions, as well as with the older literary traditions of Scotland, and was thus able to throw off the corrupting influences of a sentimentalism and artificiality which welcomed him as a "heaven-taught plowman." His work, with its sources deep in native folk song, was at the same time strongly influenced by the antiquarian movement which made available the texts of much older Scottish poetry, both popular and literary. Burns thus represents the fine flower of the tradition begun by Watson and Ramsay and other late 17th and 18th century writers and collectors of Scottish songs.

19th and 20th Centuries.—Not that Scottish literature disappeared with Burns. Even in the 18th century, there had developed a strong Scottish culture expressing itself in English—the names of the historians, philosophers, and critics of 18th century Edinburgh alone make one of the most impressive lists in the history of any civilization—and there persisted throughout the 19th century a tradition of Scottish writing (though not writing in Scots) which enables us to single out, for example, Thomas Carlyle (1795–1881, q.v.), as a Scottish rather than an English writer.

The Scots language, breaking up into a series of dialects, became confined either to incidental dialogue in fiction (as in the novels of Sir Walter Scott and John Galt), or to a kind of poetry so limited in scope (for a dialect cannot fully bear the burden of a national language) that it easily founded a corrupt and sentimental tradition, dealing with stock properties and emotions. The collection of Scots verse published in 1846 under the title of *Whistle Binkie; a Collection of Songs for the Social Circle* illustrates the depths to which vernacular Scots poetry had sunk by the middle of the 19th century.

In fiction the record was better. Sir Walter Scott (1771–1832, q.v.), concerning himself with the fate of Scotland as it had been determined by history, produced a series of novels of which those dealing with Scottish themes are, for all their conventional plots, profound reflections of the tragi-comic implications of Scottish history and character. Other Scottish novelists played variations on the tradition founded by Scott. They include John Galt (1779–1839, q.v.), with his careful studies of Scottish manners; Robert Louis Stevenson (1850–1894, q.v.), with his characteristic interest in adventure and its relation to topography; Neil Munro (1864–1930, q.v.), with his vivid sense of Scottish history; and John Buchan, Lord Tweedsmuir (1875–1940, q.v.), with his feeling for the Scottish countryside.

The provincialism and sentimentality of so much Scottish writing in the 19th century—typified by *Whistle Binkie* and the writers of the "kailyard" school—finally provoked a reaction. After Sir James Matthew Barrie (1860–1937, q.v.) had said the last word for the kailyard—with a skill and grace which atoned for much, but left unmitigated the fundamental falseness of the picture—George Douglas Brown (1869–1902) exploded the tradition once and for all with his startling debunking novel of Scottish village life, *The House with the Green Shutters* (1901).

In the field of fiction, *Morning Tide,* by Niel M. Gunn (1891–), brought a new sensibility to bear on the Scottish scene, while the trilogy, *A Scots Quair,* by Lewis Grassic Gibbon (pseudonym of James Leslie Mitchell, 1901–1935), pointed to a new and more profound use of Scots dialect in fiction, whose great promise the author unfortunately did not live long enough to fulfill. His work, however, like that of Hugh MacDiarmid, will long remain germinal, stimulating and challenging Scotland to produce once again a literature that is both Scottish and European.

Bibliography.—Murray, J. A. H., *Dialect of the Southern Counties of Scotland* (London 1873) is still authoritative; Smith, G. Gregory, *Specimens of Middle Scots* (Edinburg 1902) and Metcalfe, W. M., *Specimens of Scottish Literature* (London 1913) are standard works. For literary history, consult: Millar, J. H., *Literary History of Scotland* (London 1903); Henderson, T. F., *Scottish Vernacular Literature, a History,* rev. ed., (Edinburgh 1910); Mackenzie, Agnes Muir, *An Historical Survey of Scottish Literature* (London 1933); Power, William, *Literature and Oatmeal* (London 1935); Muir, Edwin, *Scott and Scotland* (London 1936). The Scottish Text Society has made available most of the texts of the earlier writers. William Dunbar's *Poems* have been edited by William Mackay Mackenzie (London 1932); and Robert Henryson's *Poems and Fables* have been edited by H. Harvey Wood (Edinburgh 1933). The Saltire Society has put out some convenient selections from a number of comparatively inaccessible Scottish texts. Three excellent anthologies of Scottish poetry are *The Northern Muse,* edited by John Buchan (London 1924), *Scottish Poetry from Barbour to James VI,* edited by M. M. Gray (London 1935), and *The Golden Treasury of Scottish Poetry,* edited by Hugh MacDiarmid (London 1940).

DAVID DAICHES,
Author of "Poetry and the Modern World."

SCOTLAND, Church of. See DISCIPLINE, BOOKS OF; PRESBYTERIANISM.

SCOTT, Cyril Meir, English composer, pianist and writer: b. Birkenhead, Sept. 27, 1879. He studied under Hoch at Frankfurt and composition under Knorr. In 1899 his first symphony was produced at Darmstadt. On his re-

turn to England an orchestra suite by him was performed at Liverpool. In the years following he wrote a large number of songs, and violin and pianoforte music, all of high merit. Among his most notable works are the *Ballad of Fair Helen; La Belle Dame sans Merci; Helen of Kirkconnel* and *Nativity Hymn.* He wrote, also, two symphonies, two rhapsodies, and an opera. He wrote much on occult philosophy and its application to music, and on the relation of tone and colors. He also published several books of poems and made lecture tours.

SCOTT, David, Scottish painter: b. Edinburgh, Oct. 10, 1806; d. there, March 5, 1859. In 1827 he formed an association with some artists, who founded the Life Academy for the study of the living model. The following year he exhibited his first picture, *The Hopes of Early Genius Dispelled by Death.* In 1841 he exhibited what has generally been considered his greatest picture, *Vasco de Gama Encountering the Spirit of the Storm at the Cape,* which was subsequently purchased for the Trinity House at Leith. His whole career was an arduous struggle, not with absolute failure, but with a success far from adequate to his aspirations, and he must be looked upon as the Scottish counterpart of Haydon. His genius was of wild and incoherent character and the numerous large canvases he painted with such enthusiasm quite failed to produce the effect he anticipated.

SCOTT, Dred. See Dred Scott Case.

SCOTT, Duncan Campbell, Canadian poet: b. Ottawa, Ontario, Aug. 2, 1862; d. there, Dec. 19, 1947. He was educated at Stanstead Wesleyan College and entered the Canadian civil service in 1879. He served as deputy superintendent of the Department of Indian Affairs, 1913–1932. Throughout his life he was sympathetic to the improvement of the Indian people. His first book, *In the Village of Viger* (1896) was a collection of French Canadian stories. His verse appeared in many periodicals; he also published *The Magic House* (1893); *Labour and the Angel* (1898); *New World Lyrics and Ballads* (1905); *Via Borealis* (1906); *John Graves Simcoe* (1905); *Poems* (1926), in the *Makers of Canada* series; and his last, *The Circle of Affection* (1947). He was joint editor of the *Makers of Canada* series.

SCOTT, Fred Newton, American educator: b. Terre Haute, Ind., Aug. 20, 1860; d. Ann Arbor, Mich., May 29, 1930. He was graduated at the University of Michigan in 1884 and received his doctor of philosophy degree in 1889. He became professor of rhethoric there in 1901–1921, professor of rhetoric and journalism 1921–1927, and emeritus professor of rhetoric 1927–1930. He was university editor in 1897–1900 and president of the Modern Language Association of America in 1907. He edited many classic and standard works, was joint author of *Guide to the Literature of Aesthetics* (1890); and of numerous textbooks on the English language. He was also the author of *Introduction to Literary Criticism* (1899); *Memorable Passages from the Bible* (1906); *The Standard of American Speech* (1926); and translator (with C. L. Meader) of *Plays by Leonid Andreyeff* (1915).

SCOTT, Sir George Gilbert, English architect: b. Gawcott, near Buckingham, July 13, 1811; d. London, March 27, 1878. While still a youth he was placed by his father in the office of an architect, where his tastes drew him mainly to the study of Gothic architecture. The Martyrs' Memorial, erected at Oxford in 1841, was the first work which brought him into notice. It was followed by the new church at Camberwell, and in the same year he was the successful competitor for the rebuilding of the church of Saint Nicholas at Hamburg, which had been destroyed by fire. Among his other designs are included the cathedral church of Saint John's, Newfoundland; Glasgow University; Leeds Infirmary; chapels at Exeter College, Oxford, and Saint John's College, Cambridge; the Memorial to the Prince Consort, London; Saint Mary's Cathedral at Edinburgh, etc. Toward the close of his life he was engaged in carrying out the restoration of the cathedral at Saint Albans. Among the restorations accomplished by him are those of many English cathedrals. He was the author of *Plea for the Faithful Restoration of Our Ancient Churches* (1850); *Conservation of Ancient Architectural Monuments* (1864); *Lectures on the Rise and Development of Mediaeval Architecture* (1878); *Personal and Professional Recollections* (1879).

Consult his autobiography, *Personal and Professional Recollections* (London 1879); articles in *Builder* and *Building News* of 1878.

SCOTT, Hugh Lenox, American soldier: b. Danville, Ky., Sept. 22, 1853; d. April 30, 1934. He was graduated from the United States Military Academy, June 14, 1876 and was commissioned second lieutenant June 15, 1876; first lieutenant June 28, 1878; captain of cavalry Jan. 24, 1895; major and assistant adjutant general, United States Volunteers, May 12, 1898; lieutenant colonel and assistant adjutant general, United States Volunteers, Aug. 17, 1899; major Feb. 25, 1903. Served in Sioux expedition, 1876; Nez Percé expedition, 1877; Camp Robinson, Nebraska and Cheyenne expedition, 1878; subsequently performed routine duty, principally with the Indians of the Plains, 1878–1891; honorable mention from War Department, 1891; in charge of investigation of Ghost Dance disturbances, 1890–1891; enlisted and commanded Kiowa, Comanche, and Apache Indians, troop L, seventh cavalry, 1892, until mustered out after five years' enlistment (last Indian troop mustered out); in charge of Geronimo's band of Chiricahua Apaches, 1894–1897. On duty at Bureau of Ethnology, Smithsonian Institution, writing work on sign language, Plains Indians, North America, November 1897, until outbreak of Spanish War. He served as adjutant general of 2d and 3d divisions of First Army corps, May 1898 to February 1899; adjutant general, Department of Havana, March 1899 to May 1900; adjutant general of the Division of Cuba until November 15, when the Division of Cuba was changed to Department of Cuba; adjutant general of Department of Cuba 1900–1902, and acting governor general of Cuba; took part in turning over the government of Cuba to the Cubans, May 20, 1902; was on duty with General Leonard Wood winding up the affairs of the Military Government of Intervention in Cuba, 1902. He served in the Philippines, 1903–1906, in the establishment of civil gov-

ernment, as governor and commander of troops in Sulu Archipelago; the conquest and pacification of the Sulu Archipelago and brought about the abolishment of slavery and the slave trade therein.

On 31 Aug. 1906, he was appointed superintendent of the United States Military Academy, with rank of colonel, and served as such until 31 Aug. 1910. On 3 March 1911, he was commissioned lieutenant-colonel of cavalry, and on 18 Aug. 1911, he reached, in due course of promotion, the rank of colonel, and was assigned to command of the Third cavalry. In November 1911, he was sent by the Secretary of War on a special mission to New Mexico and Arizona to adjust Indian troubles; on 23 March 1913 was promoted to rank of brigadier-general. During year April 1913 to April 1914, he commanded the United States troops on southern border from Texas to California, at time of our difficulties with Mexico. On the breaking out of severe troubles with the Navajo Indians on Beautiful Mountain, Arizona, November 1913, he was sent there with four troops of cavalry and was so successful in settling a difficult situation that he received the commendation of both the President and the Secretary of War. On 22 April 1914, he was appointed assistant chief-of-staff, and on 17 November of same year became chief-of-staff. In January 1915 he settled by diplomacy the impending conflict on the Mexican border at Naco, Arizona. In March 1915, he settled the Piute Indian trouble at Bluff, Utah. On 30 April 1915 he was promoted to rank of major-general. In August 1915, he was sent down to the Mexican border on a special mission, and was successful in recovering property of foreigners in Mexico confiscated by General Villa. In 1917 he was a member of the United States Commission to Russia and on 26 Dec. 1917 was made commander of the 78th Division of the National Army at Camp Dix, Wrightstown, N. J. In March 1918 he was made commander of Camp Dix. From 1919 he was a member of the Board of Indian Commissioners, and was also chairman of the Highway Commission of New Jersey. In 1910 he received the L.H.D. degree from Princeton University, and in 1915 the LL.D. degree from Columbia College. General Scott is a member of the Geological Society of America, Society of American Wars, Military Order of Foreign Wars, and Society of the Spanish-American War. He is author of various monographs and reports relating to the Plains Indians.

SCOTT, Hugh Stowell, English novelist, known by the *nom-de-plume* «Henry Seton Merriman»: b. Newcastle-on-Tyne, 1862; d. Ipswich, 10 Nov. 1903. He was a short while in business, made numerous sea voyages, finally devoted himself wholly to literature, and from the appearance of his novel 'The Phantom Future' in 1889 wrote a long series of somewhat melodramatic works of fiction, particularly successful when dealing with Russia and Nihilistic plots. His best book was perhaps 'The Sowers' (1896). Others are 'Suspense' (1890); 'With Edged Tools' (1894); 'Flotsam' (1896); 'Roden's Corner' (1898); 'The Isle of Unrest' (1900); 'The Vultures' (1902).

SCOTT, John Morin, American soldier and legislator: b. New York, 1730; d. there, 14 Sept. 1784. He was graduated at Yale University in 1746, and engaged in practice in New York. He was an early supporter of American rights against the British Crown, was one of the Sons of Liberty and an advocate of extreme measures. He was a leading member of the New York General Committee in 1775, and a delegate to the Provincial Congress in that year, In 1776 he was appointed brigadier-general in the Continental Army, and he participated in the battle of Long Island. He was secretary of State for New York in 1777–79, and served in Congress in 1780–83.

SCOTT, James Brown, American authority on international law: b. Kincardine, Ont., 3 June 1866. He graduated from Harvard in 1890, and studied international law at Heidelberg and Paris. After some years in academic work, he was appointed solicitor to the Department of State in 1896, serving until 1910. He served as technical adviser to many important commissions and conferences, including the Hague Peace Conference in 1907, the Peace Conference in Paris in 1919, and the Conference on Naval Disarmament in 1922. From 1915 he was president of the American Institute of International Law, and 1925–29 president of the Institute of International Law. From 1910 he was trustee and secretary of the Carnegie Endowment for International Peace. His books include 'The Hague Peace Conference of 1907' (1909); 'The United States of America' (1920); 'Robert Bacon, Life and Letters' (1923). Died Annapolis, Md., 25 June 1943.

SCOTT, Levi, American Methodist Episcopal bishop: b. Odessa, Del., 11 Oct. 1802; d. there, 13 July 1882. He was chiefly self-educated, was licensed as a local preacher in 1826 and in 1834–36 he was presiding elder of the Philadelphia Conference. He was principal of the Dickinson Grammar School in 1840–42, and was connected with the Methodist Book Concern, New York, in 1848–52. In 1852 he was elected and ordained bishop.

SCOTT, Orange, American clergyman: b. Brookfield, Vt., 13 Feb. 1800; d. Newark, N. J., 31 July 1847. He entered the New England Conference of the Methodist Episcopal ministry in 1822; was presiding elder of the Springfield, Mass., district in 1830–34, and of the Providence, R. I., district in 1834–35. From 1833 he was a zealous anti-slavery worker, and failing to receive the support of his bishop he withdrew from the Church in 1842. In 1843 he organized the Wesleyan Methodist Church at Utica, N. Y., becoming its president. He was editor of the *True Wesleyan*, an anti-slavery and anti-episcopal publication, in 1842–44. Failing health compelled his retirement from the ministry in 1846. Author of 'An Appeal to the Methodist Episcopal Church' (1838).

SCOTT, Sir Richard William, Canadian statesman: b. Prescott, Ontario, 24 Feb. 1825; d. Ottawa, 23 April 1913. He was admitted to the bar in 1848; was mayor of Ottawa in 1852; was elected a member of the Canadian assembly in 1857–63, and of the Ottawa assembly in 1867–73, where he was speaker in 1871–73. He was also member of council and commissioner of the Crown lands of Ottawa in 1871–73. He was a member of the Dominion Senate from 1874, and was Secretary of State

in 1874–78 and again in 1896–1908. He secured the enaction of the separate school act for the province of Ontario, and the Canadian temperance law known as the "Scott Act." He was knighted in 1909.

SCOTT, Robert Falcon, English naval officer and Antarctic explorer: b. Outlands, Devenport, 6 June 1868; d. Antarctic regions, 29 March 1912. He was educated at Stubbington, Fareham, and entered the navy in 1882. He become interested in Antarctic exploration and in 1900 after his promotion to commander he began preparations for his first exploring tour. In 1901–04 he commanded the Royal Geographic Antarctic Expedition, discovered Edward VII Land and reached the farthest point south then penetrated, lat. 82° 17′, long. 163°. Returning in 1904 his achievements were highly acclaimed. He was appointed naval assistant to the First Lord of the Admiralty in March 1909 but resigned later in that year to make preparations for his second journey of exploration in the Antarctic regions. He set out in 1910 on the *Terra Nova,* and established headquarters at MacMurdo Sound late in that year. (See ANTARCTIC REGIONS — *Exploration*). With four others in the party making the last part of the journey he reached the South Pole 18 Jan. 1912, after the longest sledge journey ever made, 1,842 miles. Here awaited him the bitter disappointment of the discovery that Amundsen had gained the Pole five weeks earlier. Scott photographed the tent surmounted by the Norwegian flag left by Amundsen and carried with him the letter to King Haakon according to the request left by his victorious rival. Scott's observation placed the pole only one-half mile from the point selected by Amundsen, and he planted the British flag there, made the necessary observations and set out upon the return journey. From the first ill-fortune dogged them; two of the party succumbed while Scott and the other two reached a point but 11 miles from One Ton Base and 155 miles from MacMurdo Sound on 20 March, with provisions for two days. They were held there by a blizzard and all died of hunger and exposure 29 March. Scott wrote in his diary until the last day, completing his records and leaving letters to the families of his companions, his own family, friends and officers, all stamped with matchless spirit. His observations of the expedition were in excellent order and of high scientific value. These and his diary were later published in the same style as his account of the first journey. The bodies of Scott, Wilson and Bowers were recovered in the spring of 1913. The officers of the navy contributed the funds for a bronze monument of Scott executed by his wife — who after his death was by Royal order known as Lady Scott — at Waterloo Place, London, in 1915. Author of 'Voyage of the Discovery' (2 vols.. 1905); 'Scott's Last Expedition' (posthumous, 2 vols., 1913).

SCOTT, Robert Kingston, American soldier and governor: b. Armstrong County, Pa., 8 July 1826; d. Napoleon, Ohio, 13 Aug. 1900. He studied medicine and engaged in practice in Henry County, Ohio, in 1851–57, later entering the mercantile business. In 1861 he was commissioned lieutenant-colonel in the 68th Ohio regiment, and in 1862 he was promoted colonel. He took part in the campaigns in Tennessee and Mississippi, and was commissioned brigadier-general of volunteers 12 Jan. 1865. He was assistant commissioner of the Freedman's Bureau in South Carolina in 1865–68 and was elected governor of South Carolina in 1868 and in 1870. He was charged in 1871 with being party to a fraudulent overissue of State bonds, but cleared himself and defeated the movement to impeach him. His administration was further complicated by the activities of the Ku-Klux-Klan, which compelled him to appeal to President Grant for United States troops to put down the disorder. He removed to Napoleon, Ohio, upon retiring from office, and in 1880 he shot and killed Warren G. Drury, but was acquitted on the grounds that it was accidental.

SCOTT, Thomas, English Anglican clergyman and Bible commentator: b. Braytoft, Lincolnshire, 4 Feb. 1747; d. Aston Sandford, Buckinghamshire, 16 April 1821. Possessing a strong love for learning he obtained a wide knowledge of both Latin and Greek, and in 1773 took orders in the Church of England. Through his friendship with John Newton he became an ardent Calvinist, defending Calvinism both in the pulpit and in the public press. He was chaplain of the Lock Chapel, London, in 1785–1801, and was then appointed rector of Aston Sandford, where he remained until his death. His reputation rests chiefly on his 'Commentary on the Bible' (1788–92), of which it is estimated that 100,000 copies have been sold. His other publications include 'The Force of Truth' (1779); 'Remarks on the Bishop of Lincoln's Refutation of Calvinism' (1812), etc. His collected 'Theological Works' were published (5 vols., 1805–08; 10 vols., 1823–25).

SCOTT, Thomas Alexander, American railway manager: b. London, Pa., 28 Dec. 1824; d. Darby, Pa., 21 May 1881. He entered the service of the Pennsylvania Railroad in 1850; became its general superintendent in 1858, and its vice-president in 1859. His services as superintendent of all government railroads and telegraph lines at the beginning of the Civil War placed him in the ranks of men of extraordinary ability, from which he was appointed Assistant Secretary of War in August 1861. This post he resigned in the following June, but re-entered the government service later and achieved distinction in the rapid construction of railroad lines necessary to the relief of General Rosecrans at Chattanooga. Again entering the service of the Pennsylvania Railroad, he inaugurated the policy of securing control of Western railway lines for the purpose of operating them in conjunction with the Pennsylvania lines. From 1874–80 he was president of the Pennsylvania and at various times of other lines.

SCOTT, Sir Walter, Scotch poet and novelist: b. Edinburgh, 15 Aug. 1771; d. Abbotsford, 21 Sept. 1832. He was the ninth child of Walter Scott, a writer to the Signet (lawyer), who belonged to the strenuous Border clan of Buccleugh, and of Anne Rutherford, a representative of another famous family. There were 11 other children, six of whom died in infancy. Walter at the age of 18 months suffered from spinal meningitis which caused a permanent

lameness of his right leg. On account of this he was early sent to the country, where he learned to love nature. Later his imagination was impressed by a journey to Bath and London. At the age of seven he was entered at the school in Edinburgh, where he displayed a love of sport and of good reading, though no great aptitude for hard, systematic study. For a short time he was at school at Kelso, where he formed his friendship with James Ballantyne. All accounts show that he was a manly, attractive boy who loved stories, poems like 'The Faërie Queene,' ballads and family legends.

In November 1783 he entered the University of Edinburgh, where his course was impeded by illness and his desultory habits were not overcome. His knowledge of the classics was slight, but he learned something of the chief Romance literatures and, while riding or walking for his health, he laid the foundations of his immense stock of antiquarian learning. In 1786 he was apprenticed to his father and, strength having come to him, he developed systematic habits of labor. He attended law lectures and debating clubs and in 1792 was called to the bar; but his interest in literature and history was no less than it had been, and he enjoyed the convivial society of his fellow law students. Despite his lameness, he was tall, strong, athletic and manly in appearance, full of life and merriment, and attractive to both sexes. An early attachment to a pretty young woman was to be expected, but impediments presented themselves and Scott was left with memories which bore witness to what is thought to have been "the strongest passion of his life."

His early work at the bar did not interfere with his making excursions into the Highlands and along the Border, which added to his stock of ballads and legends and gave him an extraordinary insight into the character of his countrymen. The life with which he came in contact had its seamy side, especially with respect to intemperance, but his was a romantic temperament that was not to be contaminated. A new interest also came to him in 1792, when, with his friend William Erskine, he began to study German. A few years later he attempted a paraphrase translation of Bürger's 'Lenore,' which he was persuaded to print along with another imitation of a ballad by the same author. This led to an introduction to "Monk" Lewis (q.v.), who brought about the publication in 1799 of Scott's translation of Goethe's 'Götz,' and persuaded his young friend to write some more ballads. Having thus had a taste of the pleasure of writing and publishing, though his success was far from dazzling, the young lawyer made plans to have his collection of ballads printed by his friend Ballantyne.

Meanwhile, his income from his profession had increased, and he had fallen in love with the attractive daughter of a French refugee, Charlotte Mary Carpenter (Charpentier). She had a small income settled on her, so that marriage did not seem a rash step. They took it in December 1797 and lived together congenially, although it does not appear that she was a specially qualified helpmate. In 1799 Scott was appointed sheriff-depute of Selkirkshire with a salary of £300 and few duties. Soon after, he prosecuted with energy the task of editing and publishing his important 'Minstrelsy of the Scottish Border,' the first two volumes of which appeared in 1802, the third in 1803. This contained some imitations of the old ballads, but fortunately did not include a narrative poem on the legend of Gilpin Horner, that was at first intended for it. The excluded poem, written in the free measure of 'Christabel' which a friend had recited to Scott, was slowly elaborated into 'The Lay of the Last Minstrel,' which was published early in 1805 and achieved great success. Here the creative genius of Scott first manifested itself in marked powers of narration, characterization and description, though scarcely in what may be called the strictly poetic gifts of high imagination, inevitable phrasing and noble harmony.

He now determined to follow literature seriously, but also to secure a more definite income than could be had from that or from his not specially brilliant work at the bar. With this end in view he undertook to perform the reportorial duties of an infirm clerk of session, who was to keep the emoluments of the office till his death or, as it turned out, until he was pensioned. Six years later (1812) Scott came into the comfortable salary of £1,300, but he had given much time to the clerkship and had done in addition work that would have worn out any less herculean constitution. He took some interest in politics, became a partner in James Ballantyne's printing business, proposed publishing schemes, wrote articles and edited books, working early in the morning, took rides (especially when he was at his beautiful home of Ashestiel near Selkirk), answered correspondents faithfully and yet found time for reading and study. There is scarcely another such energetic and copious genius of a high order in several spheres to be found in the annals of English literature.

His most important creative works during this period were 'Marmion' (1808) and 'The Lady of the Lake' (1810), which increased his fame as a poet; but they represent only a small part of his labors. He edited 'Dryden' in 18 volumes (1808), prefixing an elaborate biography; he superintended a new edition of the 'Somers Tracts' in 13 volumes, to say nothing of about eight smaller undertakings of a similar kind; he helped to establish *The Quarterly Review*, and he formed an unlucky partnership with John Ballantyne, brother of James, to conduct a publishing business. If they could have confined themselves to publishing Scott's poetry, even after the unenthusiastic reception of 'Rokeby' (1813) showed Scott that he could not successfully rival Byron and that his own talents must be exercised in another sphere, the partners, despite John Ballantyne's unbusinesslike habits, might have made a passable success; but Scott thought himself a born promoter and literary adviser, and he was generous to a fault with authors who were his friends. Miss Seward's works, Beaumont and Fletcher's plays edited by Weber, *The Edinburgh Annual Register* and other undertakings fell so flat it seemed best in 1813 to wind up the publishing business.

These difficulties were tided over by loans and by the transfer of more or less worthless books to the publisher Archibald Constable, and the success of the "Waverley" novels for some years made Scott feel more confident of his financial position than a prudent man should have felt. His was, indeed, a glorious genius

with a splendid energy to match, but he had also costly tastes which he aspired to gratify on a magnificent scale. His social position meant much more to him than his fame as a writer, and to maintain and increase that position he thought that he must acquire large estates and dispense a profuse hospitality. He began to realize his dream in 1812 when he bought the small farm of Abbotsford. Then he added one piece of land after another until he had spent about £30,000; he built himself a castle, and he lived on a scale which, in view of his tangled affairs, even his large income did not justify. It was only the discovery of his incomparable gifts for prose romance that his financial ruin was postponed for so long.

Early in July 1814, just after the edition of Swift in 19 volumes marked the culmination of Scott's career as an editor though not as a critic, the romance 'Waverley, or 'tis Sixty Years Since,' an anonymous story dealing with the period of the Young Pretender, made its appearance and took the novel-reading world by something like a storm, six editions being needed before the close of the year. Scott had begun the tale as far back as 1805, the year of the «Lay,» but Erskine and James Ballantyne, who wanted another well-paying poem, discouraged his attempt, and the easy-tempered author put it aside. In 1808 his attention was again directed to historical fiction through the fact that he undertook to prepare for the press an unfinished romance by the antiquary Joseph Strutt, entitled 'Queenhoo Hall.' He had always had a faculty for narrative and had enjoyed the tales and novels of others, especially, in recent years, the Irish stories of Miss Edgeworth (q.v.). We have already seen that the comparative waning of his poetic fame before that of Byron — illustrated by the failure of 'The Bridal of Triermain' (1813) which was anonymous, and to be confirmed later by the reception of 'The Lord of the Isles' (1815) and of 'Harold the Dauntless' (1817) — led him to think that he must transfer his energy to other fields, and he would probably have tried prose fiction again, sooner or later, even if a famous accident had not recalled his early attempt to his mind. One day at the end of 1813, while searching for some fishing tackle, he found the manuscript of his forgotten tale in a drawer. He read it over and determined to complete it. This time Erskine had the good sense to approve his friend's experiment, and Scott, writing with his phenomenal steadiness and rapidity, finished the last two-thirds of the book in three weeks. He did not put his name to it, partly for fear of losing some of his reputation if it failed, partly because novels were still looked upon in the main as an inferior form of literature in which a dignified officer like a clerk of session would not be expected to dabble.

Of course his fears proved to be ill-founded and there was no necessity for his preserving his anonymity, but he seems to have liked the mystery involved, and perhaps he thought that by remaining «The Great Unknown» he appeared to be less of a professional man of letters and in consequence more of a country gentleman of high standing. There have been squeamish people who could not easily forgive Scott for his innocent deceptions and his failure to come out into the open as a proud representative of his art; but it is not difficult to understand him and it seems idle to be irritated with him. After all, he did not succeed thoroughly in his attempt to remain anonymous, for competent critics like John Wilson (q.v.) saw in the author of the novels the man who had written the poems and edited the ballads. The matter was enough discussed, however, to lead to the writing of J. L. Adolphus's «Letters» to Heber on the Waverley Novels and the question of their authorship (1821), but even after this unmasking Scott continued to wear his tenuous disguise for about six years.

'Waverley' was followed shortly by 'Guy Mannering,' which illustrated his genius as a painter of Scotch life and a revealer of Scotch character — especially in the lower ranks of life. Like its predecessor it was dashed off, but was none the less immensely successful. Scott was delighted, particularly as money began to flow in and he was thus enabled to pay obligations and buy more land. He visited London and was over-enchanted at the flattering reception given him by the Prince Regent; but then Scott was a born Tory and consequently not likely to see the spots in a royal sun. His cordial relations with Byron were much more to his credit, especially as he championed that unfortunate poet when all England was crying out upon him. Later he visited Waterloo and met Wellington, who greatly impressed him. The literary results of this tour, 'Paul's Letters to His Kinsfolk' and 'The Field of Waterloo,' a poem, were failures; yet Scott was a great martial poet, would probably have been a soldier if he had not been lame and could scarcely have had a more congenial subject. Fortunately no decline was visible in 'The Antiquary'; and in 'Old Mortality,' which came later in 1816, forming with 'The Black Dwarf' the first series of 'Tales of My Landlord,' Scott produced a story which in construction, characterization, historical imagination and sympathy, power of description and broad human interest, ranks deservedly, not only very high in the list of his own creations, but as one of the masterpieces of English fiction. The style is not flawless, the psychology is not penetrating, the art in general is less subtle and refined than that to which the novelists who have followed in Scott's wake have accustomed us; but in the essential points of wholesomeness and truth to nature and of large, copious, equable creative powers, Scott, as his influence upon other lands and generations plainly shows, has little reason to fear comparison with any of his successors.

At the close of 1817 'Rob Roy' followed and six months later came 'The Heart of Midlothian,' which to many readers marks the culmination of Scott's genius as a novelist. The public responded heartily to every fresh appeal, but, unfortunately, Scott's popularity was used as a club to force publishers to take over the worthless stock of his publishing firm, and Scott and the Ballantynes were inextricably involved with Constable, who finally became Scott's sole publisher and dragged him down in his own failure. Meanwhile, the tragic 'Bride of Lammermoor,' which appealed so deeply to the sombre genius of Poe, and 'The Legend of Montrose' appeared in 1819, despite the fact that Scott had suffered tortures from a stomachic trouble. The heroic way in which he dictated the 'Bride' to Laidlaw and John

Ballantyne is well known, as is also the fact that, when he got up from an illness which it was feared would prove fatal, he could not recall «a single incident, character or conversation» in the story. Yet such was his pluck that he not only began a new book, but actually branched out into a new type of novel by crossing the border and throwing his scene back into a remote past. 'Ivanhoe,' for so this important venture was named, appeared at the close of 1819 and may be regarded, not as the best, but as the most popular of all Scott's works and as the one which made him a favorite and a great influence throughout Europe. The brilliance of its descriptions and the thrilling interest of its plot continue to atone for the carelessness of its construction and the untrustworthiness of its representation of the epoch in which its scene is laid.

Scott was now at the height of his literary and his social renown. In 1820 he accepted a baronetcy from George IV — he had previously declined the laureateship — and published 'The Monastery' and 'The Abbot.' The next year came the popular 'Kenilworth' and 'The Pirate,' followed in 1822 by 'The Fortunes of Nigel,' and in 1823 by 'Peveril of the Peak.' A stroke that seemed apoplectic did not affect the power of that masterly portrayal of the age of Louis XI, 'Quentin Durward' (1823), but 'Saint Ronan's Well,' a novel of contemporary manners, has never been popular, a fate shared by 'Redgauntlet' (1824) and by the first of 'The Tales of the Crusaders' (1825) — 'The Betrothed.' The companion of the last named, 'The Talisman,' revealed, however, the old Scott; but despite the merits of this and of 'Ivanhoe' and 'Kenilworth' and the greatness of 'Quentin Durward,' the novels of this second period do not deserve to rank with those of the first. The stories of his period of financial ruin, 'Woodstock' (1826), 'The Fair Maid of Perth' (1828), 'Anne of Geierstein' (1829), were the work of a still vigorous and an even more heroic man; those of his complete physical breakdown, 'Count Robert of Paris' and 'Castle Dangerous' (1831), call for no criticism.

Meanwhile, the crash had come. Scott, confident in his powers, had not narrowly scrutinized his relations with the Ballantynes and Constable and, in his mania for lands and buildings and lavish hospitality, he had raised money on Constable's notes given for novels yet unwritten. A general period of depression came on and Constable failed in January 1826, bringing down with him the firm of James Ballantyne and Company, of which Scott was a partner. The result was that as Ballantyne was practically without resources, Scott felt bound in honor to pay off alone a debt of nearly £120,000. How he set to work on 'Woodstock,' how he refused all offers of help, how he made in two years, especially through his 'Life of Napoleon Buonaparte' (1827), the enormous sum of £40,000, how he bore the loss of his wife (1826) and his own infirmities, how he turned his pen to every possible task of profit — 'Tales of a Grandfather' (1829) combined pleasure with profit, — how he wrote admirable prefaces for a new edition of his novels — all this is familiar to the reader of Lockhart.

Early in 1830 he had a paralytic stroke and after that his efforts to save Abbotsford, where his creditors let him continue to reside, as the seat of the family he had so longed to establish, became truly pathetic. In April 1831 he had a still more serious stroke and a little later he suffered perhaps even more acutely from the rude treatment he received from the mob at Jedburgh, where he had gone to protest against the proposed reform of Parliament. A born conservative and ever a true child of the past, it was time for him to say good-bye to a world that was entering upon a series of rapid and far-reaching changes. After his last novel had been published, it seemed that he ought to try a milder climate in order to prolong his life. The government offered him the use of a frigate; and, after a notable parting with Wordsworth, he set out for Plymouth to take it. He visited Malta, Naples and Rome, then the Tyrol and the Rhine region. At Nimeguen, on 9 June 1832, he was severely stricken and was shortly after brought home to Abbotsford, where, on the afternoon of 21 Sept. 1832, he died, surrounded by his children.

He had been what, in his last words, he told Lockhart to be — a good man. His foibles and faults — we cannot lay the whole blame for his misfortunes on the Ballantynes and Constable — when they were not those of his class and his age, were such as detracted little from the greatness of his character, and much the same thing may be said of his defects as a writer. There have been few nobler spirits in the world's history; nor is it clear that since Milton's day a more illustrious or, take him all in all, a greater writer has been born within the lands that use the English tongue. Abbotsford yields only to Stratford as a literary shrine, but it is an ironical comment on Scott's labors to aggrandize his family that no direct male heir should welcome pilgrims to it. See GUY MANNERING; HEART OF MIDLOTHIAN: IVANHOE; KENILWORTH; LADY OF THE LAKE; MARMION; OLD MORTALITY; QUENTIN DURWARD; ROB ROY; also SCOTT, LOCKHART'S LIFE OF.

Bibliography. — The standard editions of Scott's poems and novels are those in 11 and 48 volumes with his prefaces (1829–33). The miscellaneous works fill 28 volumes in the edition of 1834–36. Of the numerous later editions mention may be made of the «Cambridge Edition» of the poems edited by H. E. Scudder (1 vol.) and of the «Border Edition» of the novels (48 vols., 1892–94) with excellent introductions, by Andrew Lang. The chief authority for Scott's life is his son-in-law, J. G. Lockhart's (q.v.) admirable biography (7 vols., 1837, but best read in the Cambridge Edition, Boston, 1902). There are short lives by R. H. Hutton ('English Men of Letters'), C. D. Yonge ('Great Writers' — with a bibliography), W. H. Hudson (1901), Lang, 'Literary Lives' (1906), Norgate, G. Le G., 'Life of Sir Walter Scott' (London 1906), Buchan, J., 'Some Notes on Sir Walter Scott' (N. Y. 1924). Attention should also be given to Scott's last 'Journals' (1890), and his 'Familiar Letters' (1894) edited by David Douglas. For criticism consult Lang's biography and introductions; F. T. Palgrave's introduction to the «Globe» edition of the poems; Leslie Stephen, 'Studies of a Biographer' (Vol. II, 1898) and 'Hours in a Library' (Vol. I); Ruskin, 'Fors Clavigera' and the histories of English literature.

WILLIAM P. TRENT,
Late Professor Emeritus of English Literature, Columbia University.

SCOTT, Walter, Canadian statesman: b. Oct. 27, 1867; d. March 23, 1938. He was educated in the public schools, and early settled in the North West Territory, where he engaged in printing and journalism. He owned and edited various newspapers in 1892–1906, and in 1900 was elected to the Canadian House of Commons. He was instrumental in creating the provinces of Saskatchewan and Alberta in 1905, became the leader of the Liberal party in Saskatchewan and served as its first Prime Minister in 1905–1917.

SCOTT, Walter Dill, American psychologist: b. Cooksville, Ill., May 1, 1869; awarded the D.S.M. for "devising, installing and supervising the personnel system in the U.S. Army, World War I."

SCOTT, William Amasa, American political economist: b. Clarkson, Monroe County, N. Y., April 17, 1862; d. Madison, Wis., Nov. 6, 1944. He was graduated at the University of Rochester in 1886, was professor of history and political science in the University of South Dakota in 1887–1890; instructor and graduate student at Johns Hopkins University, 1890–1892, and received his Ph.D. from that institution in June 1892. He became assistant professor of political economy at the University of Wisconsin, 1892–1893; associate professor there, 1893–1897, professor 1897–1931, and emeritus professor from 1931–1944. From 1900 until 1927 he had acted as director of the school of commerce in that institution. In 1911 he received the honorary degree of LL.D. from the University of Rochester. In addition to many articles and monographs on economic and educational topics in encyclopedias and periodicals, he published *Repudiation of State Debts* (1893); *Money and Banking* (1903; revised and enlarged, 1910–16–26); *Money* (1914); *Banking* (1914); chapter on "The Austrian School and Recent Developments" in Ingram's *History of Political Economy* (new and enlarged edition, 1915); an introduction to *Recent Literature on Interest* (1884–1899) by Eugen von Böhm-Bawerk, translated from the German; and *The Development of Economics* (1933).

SCOTT, William Bell, Scottish poet and painter, brother of David Scott (q.v.): b. Edinburgh, Sept. 12, 1811; d. Perthshire, Nov. 22, 1890. He received his art education from his father, an engraver, and in 1834 he published his first poetry in magazines. His picture, *The Old English Ballad Singer,* was exhibited in 1838 and established his reputation as a painter. For many years he exhibited in the Royal Academy but his main activity was literary. His poetical works include *The Year of the World* (1846); *Poems by a Painter* (1854); and *Ballads* (1875), etc. His other writings include *Lectures on Art* (1861); and *Albert Dürer: His Life and Works* (1869).

SCOTT, William Berryman, American geologist, brother of Gen. H. L. Scott (q.v.): b. Cincinnati, Ohio, Feb. 12, 1858; d. Princeton, N. J., March 29, 1947. He was graduated at Princeton in 1877 and obtained his Ph.D. at Heidelberg in 1880. From 1884 to 1930 he was professor of geology and paleontology at Princeton. He was joint editor of the 9-volume reports of the Princeton expeditions to Patagonia, which he also conducted. The recipient of numerous scientific awards, he was president of the American Philosophical Society in 1918–1925. His works include: *The Theory of Evolution* (1917); *Physiography* (1922); and *The Mammalian Fauna of the White River Oligocens* (1935–1941).

SCOTT, Winfield, American soldier: b. near Petersburg, Dinwiddie County, Va., June 13, 1786; d. West Point, N. Y., May 29, 1866. After study at William and Mary College in 1805, he read law at Petersburg, and having obtained his license, rode the circuit and was retained in several causes. In 1808 he obtained a captain's commission in the United States army, and in 1809 embarked with his company from Norfolk to New Orleans. On June 18, 1812 war was declared by Congress against Great Britain (see WAR of 1812). On July 6 following, Scott was commissioned the lieutenant-colonel of the 2d Artillery. He at once was ordered to mobilize his regiment at Philadelphia and soon after, at his request, to proceed to the Canadian frontier. He arrived at the headquarters of Brig. Gen. Alexander Smyth October 4. The affair at Queenstown took place on October 13. Scott did not take part in the successful attack on the heights, but commanded the American forces in the ensuing battle, and after brisk fighting was obliged to surrender to much superior numbers. He was soon after exchanged, in March 1813, was appointed adjutant general with rank of colonel, and at about the same time was promoted colonel of his regiment. With the regiment he joined Gen. Henry Dearborn on the Niagara frontier, became Dearborn's chief of staff, led the successful attack on Fort George May 27, commanded the rear guard in the retreat from Stony Creek to Fort George and cooperated with the naval forces in the descent on Burlington Heights and York. Promoted March 9, 1814 to be brigadier general, he established a camp of instruction at Buffalo. Scott's brigade and Ripley's crossed the Niagara July 3, 1814; Fort Erie was invested and captured; and on the 4th Scott moved toward Chippewa. On July 5, occurred the Battle of Chippewa (q.v.). Scott greatly distinguished himself, and Gen. Jacob J. Brown, commanding, declared that to Scott more than any other the American victory was due. The Battle of Lundy's Lane (q.v.) followed on the 25th, where Scott again displayed great ability. These battles, both won chiefly by Scott, fully established American military prestige. For his services, Scott received a gold medal from Congress, and was made brevet major general (from July 25). He declined to act as secretary of war, and was in Europe in 1815–1816. In 1826 he was made president of a board of army and militia officers convened at Washington for the consideration of various military questions, and in 1829 was assigned to the command of the Department of the East. In July 1832 he was ordered to Illinois to take command of the forces in the Black Hawk War (see BLACK HAWK), and left Buffalo for Chicago with 1,000 troops. He was not in the active campaign, but cooperated with Governor John Reynolds of Illinois in concluding treaties with the Sacs, Foxes, Winnebagoes, Sioux and Menominees. At the time of the nullification troubles he was sent to South Carolina (1831–1832), where he was successful

in averting civil war. He prosecuted the Seminole and Creek campaigns in Florida (1836), and superintended the removal of the Cherokees from Georgia to their reservation west of the Mississippi. On June 25, 1841 he became major general and general in chief of the army. In 1839 at the Whig Convention at Harrisburg, Pa., Scott was presented as a candidate for the Presidency, though he urged Clay as first, Harrison as second, choice and the 62 votes cast for him went ultimately to Harrison. He was ordered on Nov. 23, 1846 to Mexico to take charge of the forces there. He assembled his troops at Lobos Island, moved transports in February, landed at Vera Cruz March 9 and effected its surrender March 29. From this time he proceeded on the uniformly victorious campaign which practically closed the war by his entry into the City of Mexico on September 14. (For complete account see MEXICAN WAR and articles on various battles.) At the close of the war Scott relinquished the command to Gen. W. O. Butler, and returned to the United States, where he received a gold medal from Congress, and was a candidate in 1848 in the Whig Convention which nominated Taylor for the presidency. In 1852 he was defeated by Franklin Pierce, and in 1855 made brevet lieutenant general. In 1859, when the American and British governments were adjusting the northwestern boundary question, he was sent to Puget Sound to adjust the difficulties caused by the precipitate occupation of San Juan Island. At the outbreak of the Civil War, he took command at Washington Dec. 12, 1860, provided for the safety of the national capital, and the organization of the army, but resigned the command to McClellan Nov. 1, 1861. Scott was a strict disciplinarian and this, with his formality, led to his army nickname of "Old Fuss and Feathers." As to his skill as a military leader there can be no question. He gained notable distinction in two wars. Webster, in a Senate speech (Feb. 20, 1848), called the Mexican War "the most brilliant campaign on recent military record," and Grant writes of the faultless strategy at Churubusco. His political defeats in no way detracted from his reputation. He published *General Regulations for the Army* (1825) and *Infantry Tactics* (1835).

Consult *Memoirs* (1864); Barnes, J. W., *Giant of Three Wars* (1903); Elliott, C. W., *Winfield Scott, the Leader and the Man* (New York 1937); Smith, A. D. H., *Old Fuss and Feathers, the Life and Exploits of Winfield Scott* (New York 1937).

SCOTT, Life of. John Gibson Lockhart's biography of Sir Walter Scott is often mentioned as a serious rival of Boswell's *Life of Johnson.* The works have many points in common. Each has for a subject a great man in English literature; each was written by a man intimately acquainted and thoroughly in sympathy with the subject; each is constructed upon a large plan, with canvas filled even to the smallest details. Furthermore, Lockhart followed the autobiographical plan of Boswell. Beyond these resemblances, however, there are striking dissimilarities. So far as command over language is concerned, Lockhart was probably superior to Boswell; but as a biographical artist he was clearly inferior. He did not possess Boswell's dramatic skill, nor his ability to report a conversation, nor his discrimination in selecting the most important material.

The *Life of Scott* is probably the longest biography of established rank in the English language. Carlyle, who reviewed it before the publication of the seventh and last volume, deplored what seemed to him the excessive length of the narrative. "Study to think it nothing miraculous," he wrote, "that seven biographical volumes are given where one had been better . . . Scott's biography, if uncomposed, lies printed and indestructible here, in the elementary state and can at any time be composed, if necessary, by whosoever has a call to that." Carlyle's opinion has in the main been justified. In 1911 Sir Sidney Lee expressed his conviction that "Lockhart's merit is mainly due to the excellence and the abundance of the raw material provided for him in Scott's ample journals and correspondence." In short, the *Life of Scott* is a Gothic cathedral, overawing us by its size and magnificence, rather than a Greek temple, gaining our admiration by its artistry and simplicity.

With all of its limitations, however, the biography is great. The combination of subject and biographer is sufficient to guarantee its greatness, and, to a certain extent, its finality. Lockhart, personally acquainted with Scott since May 1818, became his son-in-law on April 29, 1820, when he married Sophia Scott. The biography was completed in 1838, six years after Scott's death. Lockhart had access to all documents; his work, therefore, together with the journals of Scott later published in full, must always remain the great mine of information from which later biographers must dig. In writing the life of his father-in-law Lockhart had set "the truth and the fear of God" before his eyes; his work, consequently, is not a panegyric; but, like Boswell's *Life of Johnson,* a straightforward account of faults as well as of virtues. Professor Hugh Walker, in *The Literature of the Victorian Era* (pp. 920-923), highly commends Lockhart upon the skill and insight with which he interprets certain manifestations of Scott's character, particularly his love of display and his consequent lavish expenditure. The style of the biography is admirable; several passages, notably the description of Scott's death, are among the best in English literature. All in all, the work, by its very length and exhaustiveness, forms a noble monument to the memory of a man who did all things on a large and magnificent scale.

WALDO H. DUNN.

SCOTT CITY, city, Kansas, and seat of Scott County, 72 miles northwest of Dodge City, altitude 2,970 feet above sea level. Transportation facilities are the Santa Fe, Missouri Pacific railroads, state and federal highways, and there is a municipal airport.

The community is largely agricultural, with an oil field and refinery in the southern part of the county. In 1951 there was under construction a new electric power plant which would serve several cities and counties with electric power. In Scott County there were over 50,000 acres of land under irrigation from deep-water wells. A great many of these wells were powered by electricity.

History.—Scott City was named in honor of Gen. Winfield Scott. The nearby 1,280-acre Kansas State Park contains the ruins of El Quartelejo, the northernmost Indian pueblo in the United States, which many historians believe is Quivira, for which Coronado was seeking on his journey through the southwest. The city was incorporated in 1887. The government is by mayor and council. Pop. (1950) 3,204.

SCOTTDALE, skŏt'dāl, borough, Pennsylvania, in Westmoreland County, altitude 1,042 feet; on the Baltimore and Ohio and the Pennsylvania railroads; by rail, 48 miles southeast of Pittsburgh; in direct line, 16 miles south of Greensburg, the county seat. Surrounding the city is an area partly agricultural, producing potatoes, grain, and corn, and partly devoted to the mining of bituminous coal. Manufactures include the making of castings, machine parts, and tool handles. There is a public library. The borough has a number of musical organizations, including a choral club, a men's chorus, and several bands. Scottdale was named for Thomas A. Scott, who became president of the Pennsylvania Railroad Company in 1874. Government: burgess-council. Pop. (1950) 6,249.

SCOTTI, Antonio, Italian operatic baritone: b. Naples, Jan. 25, 1866; d. Feb. 26, 1936. He studied under Mme. Trefari Paganini, and made his début in Malta in 1889. His success was instantaneous, and he filled engagements in Italy, South America, Spain, Russia and other countries. In 1899 he sang at Covent Garden in London, and in the same year was engaged for the Metropolitan Opera House in New York. He thereafter remained a member of its company. His most famous part was that of Scarpia in *Tosca.*

SCOTTISH GAELIC LITERATURE. The Gaelic spoken in the Highlands and islands of Scotland forms one of the subdivisions of the Gaelic language, the other two being Irish and Manx. (See CELTIC LANGUAGES; GAELIC LITERATURE.) It was introduced into the southern part of Argyll by the Dalriads, who emigrated from Ireland in the 6th century, and there established the subkingdom of Dalriada. The language spread until it became paramount, and it was used at court as late as the reign of Malcolm Canmore. Gaelic, which was the language of the district of Buchan in Aberdeenshire, in the 12th century, and was spoken in Galloway in Queen Mary's reign, gradually retired north and west beyond the Highland line, until now its strongholds are Arran and the Hebrides, the counties of Argyll and Inverness, Ross and Sutherland, and parts of Perth and Caithness.

A strong Gaelic-speaking colony was founded in Carolina in the 18th century. In 1772 the first Gaelic-speaking immigrants landed in Cape Breton Island, Nova Scotia, and in the first quarter of the 19th century some 25,000 landed in that part of Canada. Prince Edward Island, Glengarry in Ontario and other parts also received settlers who spoke the Gaelic tongue and have maintained it to the present time. One of the objects of Lord Selkirk in founding the Red River Settlement was the formation of a Gaelic-speaking colony, which, through difference in language, would be proof against any tendency to amalgamate with the Americans. Within the past half century there has been a marked revival of interest in the Gaelic literature of the Highlands, one of the proofs of which was the founding of a Gaelic chair in Edinburgh University in 1882.

For nearly 300 years Scotland and Ireland had a common literary tradition, and the tales of the great Irish legendary heroes were current in the Scottish Highlands. Adamnan's life of St. Columba, written in the island of Iona before 713 A.D., is the first literary product of Gaelic Scotland that survives. The *Book of Deer* is of the 9th century; the *Book of the Dean of Lismore,* by Sir James MacGregor and his brother Duncan, is a manuscript collection of date 1512–1526. John Knox's *Liturgy* was the first book to be printed in the Gaelic dialect (1567). Long after the invention of printing the output was small in this language; only some 20 books had been printed in Gaelic up to the time of the Rebellion of 1745. A valuable collection of manuscripts is deposited in the Advocates' Library, Edinburgh. The language has been peculiarly rich in poets, a succession of notable bards appearing for about 300 years. Among them may be cited Mary Macleod (b. 1659); John Macdonald, a member of the Keppoch family; Alexander Macdonald, an officer in Prince Charles's army; Robert Mackay (Rob Donn, 1714–1778); Ban McIntyre (1724–1812); Ewen McLachlan of Aberdeen (1755–1822), and William Livingston of Islay (1808–1870).

SCOTTISH PHILOSOPHY, School of, the school of philosophy founded by Thomas Reid, whose aim was to disprove the skeptical conclusions of Hume, which had obtained a wide vogue in Great Britain and on the Continent. Besides Reid, the most noted representatives of the Scottish philosophy were Dugald Stewart (1753–1828); Sir William Hamilton (1788–1856); W. Whewell, master of Trinity College, Cambridge (1794–1866); Henry Calderwood (1830–1897). James McCosh (president of Princeton University from 1868 to 1888) and Noah Porter (president of Yale University from 1871 to 1886) belonged to the same school, and as teachers of philosophy contributed largely to its influence in the United States.

SCOTTSBLUFF, skŏts'blŭf, city, Nebraska, in Scotts Bluff County, altitude 4,000 feet; on the North Platte River, opposite Gering, the county seat; on the Chicago, Burlington and Quincy Railroad, and served by the Union Pacific at Gering; by rail, 431 miles west of Lincoln; on state and federal highways; also airline service. In irrigated country, producing sugar beets, potatoes, beans, with stock raising as an important occupation, Scottsbluff's industrial establishments engage in the processing, canning or packing, and shipping of foods. The city has a public library, a junior college, many churches, and two hospitals; also, numerous memorials of pioneer days.

About three miles southwest of the city is the Scotts Bluff National Monument, a tract of over 2,000 acres, established in 1919. The monument, a great bluff which rises some 750 feet above the North Platte River, served as a landmark on the Oregon Trail. At the base of the monument is the Oregon Trail Museum. Government is by council-manager. Pop. (1950) 12,840.

SCOTTSBORO, city, Alabama, and Jackson County seat, 70 miles west of Chattanooga, Tenn., altitude 45 to 80 feet. It is served by the Southern Railroad. Agricultural products include cotton, corn, and hay. The chief industries are the manufacture of bedspreads, men's underwear, bath mats. There are also lumber mills, bottling works, and cotton gins. The facilities for fishing, boating, and swimming are exceptional as the county has many fresh-water lakes and streams.

The city was incorporated about 1898 and has mayor and council government. Pop. (1950) 4,731

SCOTUS, skō'tŭs, **Johannes Duns,** Franciscan theologian and philosopher, known as the Subtle Doctor: b. Maxton, Roxburgh, Scotland, 1265/1266; d. Cologne, Germany, Nov. 8, 1308. He entered the Franciscan Order in 1278 and was ordained priest in 1291. Scotus seems to have studied in Paris from 1293 to 1296 and to have returned to England to lecture on the *Sentences* of Peter Lombard at Oxford. In 1302 he was teaching at Paris, but was banished thence in June 1303 for his support of Pope Boniface VIII against King Philip IV the Fair of France. In 1304 he again taught in Paris. It is possible that he left once more for England in 1306, but he was certainly back in Paris in 1307. From that city Scotus was transferred to Cologne, where he died suddenly at the age of 42 or 43.

In the Roman Catholic Church, Scotus is the leader, with St. Bonaventura, of the Franciscan school of philosophy and theology, just as St. Thomas Aquinas is the leader of the Dominican school. Because of his depth of thought and sharpness of mind his place as philosopher and theologian is among the highest. Scotus' name has gone down to history as closely bound with the doctrine of the Immaculate Conception, of which he became the champion. See SCOTISM; SCHOLASTICISM.

The canon of Scotus' work has long been uncertain, partly because his works, which include treatises on grammar, logic, metaphysics, and theology, have descended to us mainly in reports written by his pupils, often with additions of the reporter's own composition. Recent studies have proved that certain works long attributed to Scotus are definitely spurious. The *Opus Oxoniense* and *Reportata Parisiensia,* his commentaries on the *Sentences* of Peter Lombard, are undoubtedly authentic and constitute the best source of Scotus' doctrine.

Scotus' works were edited by Luke Wadding (12 vols., Lyon 1639) and reprinted by L. Vivès (26 vols., Paris 1891–1895). A commission of Franciscan scholars headed by Father Charles Balić is preparing a critical edition of all Scotus' works (1950–).

Consult Heidegger, Martin, *Die Kategorien- und Bedeutungslehre des Duns Scotus* (Tübingen 1916); Harris, C. R. S., *Duns Scotus,* 2 vols. (Oxford, Eng., 1927); Bettoni, Efrem, *Duns Scoto* (Brescia 1946); Gilson, Étienne H., *Jean Duns Scot* (Paris 1952).

BERNARDINO M. BONANSEA, O.F.M.

SCOTUS ERIGENA, ĕ-rĭj'ĕ-nà, **Johannes,** philosopher and theologian: b. about 815; d. about 877. His literary pseudonym was JOHANNES IERUGENA or ERIUGENA (meaning perhaps "Irish-born"), for he probably was born in Ireland, but perhaps of Scottish parents. Most of the circumstances of Scotus' life are either vague or conjectural. It seems, however, that after some schooling at home he went to France, where he was attached about 847 to the court of Charles I the Bald as director of the palace school. In 851 he wrote, at the request of Hincmar, archbishop of Reims, his *De Praedestinatione* (*On Predestination*), which defended the freedom of the will and which later met conciliar condemnation. Between 860 and 862 he translated from Greek the works of the Pseudo-Dionysius, notably his *De Caelesti Hierarchia* (*On the Heavenly Hierarchy*), a treatise destined to influence profoundly the development of mysticism in France. Erigena's own chief work is his *De Divisione Naturae* (*On the Divisions of Nature,* 862–866), which incurred charges of pantheism and freethinking which have never been entirely dispelled. He is generally conceded, however, to have possessed the finest philosophical mind of his time and his *De Divisione Naturae,* though condemned by Pope Honorius III in 1225, takes its place as the first real theological *summa* in the West.

Consult Bett, Henry, *Johannes Scotus Erigena; a Study in Mediaeval Philosophy* (Cambridge, Eng., 1925); Cappuyns, Maïeul, *Jean Scot Érigène* (Louvain 1933); and Pra, Mario dal, *Scoto Eriugena* (Milan 1941).

SCOURING RUSH. See DUTCH RUSH; FERNS AND FERN ALLIES—*Equisetinæ.*

SCRAG WHALE, name loosely applied by American whalers to any lean, undersized, or immature balaenopteroid whale. Sometimes the name is applied generally to various species of these "whalebone" whales, such as (1) the finback whale of the North Atlantic (*Balaenoptera physalus*), which grows to 60 or more feet in length, and (2) the related pygmy right whale of the South Pacific (*Neobalaena marginata*), which attains a length of only about 20 feet. See WHALE.

SCRANTON, skrăn't'n, **George Whitfield,** American manufacturer: b. Madison, Conn., May 23, 1811; d. Scranton, Pa., March 24, 1861. In 1839, in partnership with his brother Selden, he purchased an iron furnace at Oxford, N. J., and operated it with great success. In 1840 he helped to form the Lackawanna Iron and Coal Company, which acquired extensive coal-bearing lands in Pennsylvania's Lackawanna Valley, including the present site of the city of Scranton, which he founded in that year. His success in smelting iron with anthracite coal (1842) and the growing railroads worked together to bring him great wealth. For several years Scranton was president of the Delaware, Lackawanna, and Western and the Cayuga and Susquehanna railroads. He served as a Republican in the House of Representatives from 1859 until his death.

SCRANTON, city, Pennsylvania, seat of Lackawanna County, situated on the Lackawanna River, about 118 miles north-northwest of Philadelphia. Hemmed by the Moosic Mountains on the east and the north and by the West Mountains on the west, it is in the heart of the rich Pennsylvania anthracite coal region. The city has a moderate climate, with a mean annual temperature of 49°F. and an average rainfall of 37 inches.

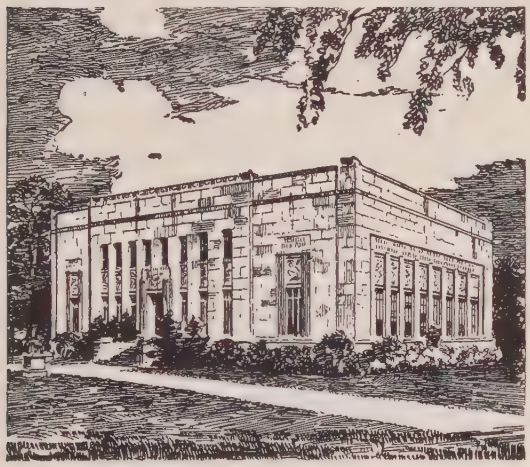
Predominantly a coal-mining center for many years, Scranton recently has developed a wide variety of new manufacturing industries. Transportation facilities are excellent. Railroads serving the city are the Central of New Jersey; the Delaware and Hudson; the Delaware, Lackawanna, and Western; the Erie; the New York, Ontario, and Western; and the Lackawanna and Wyoming Valley (electric) lines. There is an airport six miles to the southeast.

Commerce and Industry.—Scranton is the fourth largest city of Pennsylvania and a major commercial and industrial center. In addition to coal-mining operations there are extensive manufactures of carbon products, clothing, electric appliances, machinery, furniture, heating equipment, plastics, railway equipment, steel, textiles, tobacco, and paper.

Government.—The municipal government of Scranton is by a mayor and councilmen. The

Commonwealth of Pennsylvania maintains here a branch of the Superior Court, an oral school, a hospital, and other agencies. There are several agencies of the United States government located here.

Education.—Educational and cultural facilities of the city embrace a modern public school system; private and parochial schools; the Johnson Manual Training School; the Pennsylvania State Oral School for the Deaf; the University of Scranton (Catholic) for men; Marywood College (also Catholic) for women; the Scranton-Keystone Junior College; a public library with several branches; the Everhart Museum of Natural History, Science, and Art; extension schools of the University of Pennsylvania, Temple University, and Pennsylvania State College; and the library of the Lackawanna County Historical Society. The Scranton Orchestra Association, the Scranton Philharmonic Orchestra, the Community Concert Association, and the Scranton Opera Guild also contribute much to the cultural life of the community. Scranton is



Everhart Museum in Scranton, Pa.

the home of the International Correspondence Schools.

Parks and Recreational Facilities.—The city has a number of parks, playgrounds, and recreational centers. In the 145-acre Nay Aug Park are Roaring Brook, Nay Aug Falls, Lake Lincoln (now a swimming pool), the city zoo, the Everhart Museum, and various memorials, as well as playgrounds and other recreational facilities.

Notable Buildings.—Many attractive buildings adorn the city. Public buildings of note include the city hall, the county courthouse, the public library, several handsome, modern public school buildings, the Scranton State Hospital, the Everhart Museum, the United States Post Office and Courthouse, the Watres Armory, and Valley View Terrace, a government-sponsored housing project. Among the private edifices are many handsome residences, modern commercial buildings, churches, several attractive academic buildings, and the Masonic Temple and Scottish Rite Cathedral, whose auditorium has a seating capacity of 1,800.

History.—The site of Scranton was first settled about 1786 by Philip and James Abbott, brothers, originally from Connecticut, who came here, built a log cabin, and established a sawmill. About a decade later Ebenezer and Benjamin Slocum were attracted to the site, where they acquired land and operated a forge and distillery, naming the settlement Unionville, which was changed in 1816 to Slocum Hollow. In 1840 George Whitfield Scranton (q.v.), his brother Selden T., and others acquired a tract of land in the Lackawanna Valley for its coal and iron, and established at Slocum Hollow an iron forge. Here in the same year the Scrantons founded as Scrantonia (simplified in 1851 to Scranton) the city which bears their name. Later the firm of Scranton and Platt was formed, which operated here a rail mill. Out of this firm grew in 1853 the Lackawanna Iron and Coal Company. The arrival of the Delaware, Lackawanna, and Western Railroad in 1853, giving an outlet to the coal and iron of the vicinity, resulted in the rapid growth of Scranton, whose population rose to 9,223 by 1860, and 35,092 by 1870. Scranton was incorporated as a town in 1856, and as a city in 1866, at which time it absorbed the boroughs of Hyde Park and Providence, and the township of Providence. Pop. (1940) 140,404; (1950) 125,536.

Consult: Hitchcock, Frederick L., *History of Scranton and its People* (1914); Merrifield, Edward, *The Founders of Scranton* (1916).

SCREAMERS, the name given to two or three genera of birds, forming the family Palamedeidae. In the genus *Palamedea* the nostrils are oval, the head possesses a slender frontal horn more than three inches long; the wings each bear two sharp shoulder spines with bony cores, and the long toes are covered with square scales above. To this genus belongs the horned screamer (*P. cornuta*), of the Amazon Valley and Guiana, which inhabits hot morasses and swamps. This bird equals a turkey in size. The voice is shrill and loud and the birds scream in concert. The plumage is a blackish-brown above, the head and neck having the feathers marked with white.

The genus *Chauna,* of which the chaja or crested screamer (*C. cristata*) is the representative, has the tip of the bill hooked. No horn exists on the head. The name "chaja" is given to this species from the sound of its cry. It occurs in Brazil and Paraguay. It is of solitary habits. The wings possess, as in the former case, two spurs each. The color is a bluish-gray marked with black, the neck being encircled by a black collar, while a tuft of feathers on the head constitutes a crest. Round the eyes the skin is naked and of a red color. The food consists chiefly of plants and the flight is strong. The eggs are two in number.

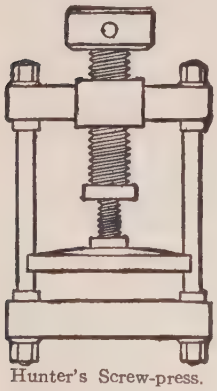
A third form (*Ischyromis derbiana*), closely related to the last, inhabits Central America. A remarkable feature of all of these birds is the great development of subcutaneous air sacs, like a thick layer of bubbles beneath the skin, which make a crackling sound when pressed. Although galline in appearance and general habits, these birds are more closely related to the ducks and geese.

Consult Evans, A. H., "Birds" in *Cambridge Natural History,* vol. 9 (New York 1900).

SCREEN, in ecclesiastical architecture, a partition of stone, wood or metal to separate different parts of the building; as, the nave or an aisle from the choir, or a private chapel from

the transept. The term is also applied to a partition extending across the lower end of a mediæval hall, forming a lobby within the main entrance doors, and having often a gallery above; also to a decorated wall enclosing a courtyard in front of a building.

SCREW, a wooden or metal cylinder having a spiral ridge (the thread) winding round it in a uniform manner, so that the successive turns are all exactly the same distance from each other, and a corresponding spiral groove is produced; also a reversed mechanism, in which the interior of a cylinder in a cylindrical hole or nut is provided with a corresponding uniform spiraled groove or thread, into which a screw (as first defined) may fit. For differentiation the primary screw is termed a male screw, and the secondary form a female screw. The male and female screw in combination form one of the six mechanical powers, being simply a modification of the inclined plane. The energy is transmitted by means of a hollow cylinder (the female screw) of approximately equal diameter with the solid one (the male screw). Hence the one will work within the other, and by turning the convex cylinder, while the other remains fixed, the former will pass through the latter, and will advance every revolution through a space equal to the distance between two contiguous turns of the thread. As the screw is a modification of the inclined plane it is not difficult to estimate the mechanical advantage obtained by it. If we suppose the power to be applied to the circumference of the screw, and to act in a direction at right angles to the radius of the cylinder, and parallel to the base of the inclined plane by which the screw is supposed to be formed, then the power will be to the resistance as the distance between two contiguous threads to the circumference of the cylinder. But as in practice the screw is combined with the lever, and the power applied to the extremity of the lever, the law becomes: The power is to the resistance as the distance between two contiguous threads to the circumference described by the power. Hence the mechanical effect of the screw is increased by lessening the distance between the threads or making them finer, or by lengthening the lever to which the power is applied. The law, however, is greatly modified by the tremendous friction induced. The uses of the screw are various. It is an invaluable contrivance for fine adjustments such as are required in fine telescopes, microscopes, micrometers, etc. It is used for the application of great pressure as in the screw-jack and screw-press; as a borer in the gimlet; and in the ordinary screw-nail we have it employed for fastening separate pieces of material together. The *differential screw*, or *Hunter's screw*, is formed of two screws, a larger and a smaller, the former being screwed internally to allow the latter to screw into it; the pitch of the two screws differs slightly, and for each turn of the chief or larger screw the progress of the point of the compound screw is the difference of pitch. Great power is in this way attained without the weakness due to a screw with fine threads. Screws for working in wood are commonly tapered, coming to a point; while machine-screws for use in metal are cylindrical and commonly flat or dull-pointed on the forward end. Exceptions are the set-screw, which has a sharp circular ridge on the forward end, to give it a bite or set when screwed down hard; and screws that are pointed or squared for some special purpose. Machine-screws were originally made by hand, a blank being forged on the anvil, and the thread being cut on a lathe or even with a file. Under this primitive system no two screws were alike, and when a screw had to be replaced it was difficult to make another that would fit. Henry Maudsley, of England, about the opening of the 19th century, gave great study to the production of uniform and accurate screws, laying the foundation for modern interchangeable machine-screws. He was followed by Sir Joseph Whitworth, who established the primary system of uniform threads subsequently accepted by leading machine-builders all over the world. Later, the Sellers standard was adopted in America and largely followed. The chief difficulty was the attaining of accurate and uniform pitch or spacing of the screw-threads, because any error was multiplied. For instance, an error of one ten-thousandth of an inch in a space between screw-threads, which would ordinarily pass unnoticed if there were only half a dozen turns, would increase with the length of the screw and number of threads, so that with 24 threads to the inch, a screw a foot long would multiply that error by 288, so that the screw would bind and jam before it would go far into its counterpart. It was found, in cutting a thread, that the very heating of the bar of metal and of the cutting tools, by their own friction, caused a variation in the threads, because of the expansion of metal under heat. But by ingenious means such errors have been compensated, and screws are now turned out very cheaply with great accuracy.



Hunter's Screw-press.

To cut a screw-thread by hand, the blank or bit of stamped metal, or a metal rod of the desired diameter, is mounted between the centres of a lathe, while a cutting tool is fixed on the slide-rest, and forced against the rotating blank, the slide-rest having a positive lateral rate of movement, so that a spiral is cut in the blank, the form of such spiral being determined by the ratio of the speed of rotation of the blank to the lateral movement of the cutting tool. This process is repeated until the thread is sufficiently deep, and it matches a master screw, which is placed beside it to test its accuracy. Another method is to use a screw-die and die-stock, which carries a pair of hardened steel cutting dies of the desired standard. These dies are placed straddle of the rod or blank, and being fixed in the die-stock, either the work or the stock is rotated until the thread is cut, the dies being pressed together gradually by a screw in the stock. Similarly a female thread may be formed with a screw-tap worked into a hole with a wrench. But in modern screw-making only the above principles are followed, screws being made on lathes specially

designed to work automatically and cut a large number of accurate screws at one operation. These machines are so thoroughly automatic, that an attendant can watch several of them, so that vast numbers of small screws can be turned out at surprisingly small cost, when their almost perfect accuracy is considered. By employing what are termed "change-wheels" on the heads of the lathes, the number of screw-threads may be altered from one standard size to another. A common principle used in screw-cutting is to employ a master-screw, or hardened screw known to be of accurate standard, as a guide for the cutting of duplicates. This master-screw carries a nut, which travels and directs the movement of the blank or bar that is being threaded. The heads of screws may be formed — (a) by upsetting or thickening the blank before cutting; or (b) by using a bar of the diameter of the head, and milling away the superfluous metal. In modern practice a milling cutter is often employed in making screws on a special machine which is half lathe and half miller. The milling cutter is mounted on a swiveling device for forming various angles in the thread. This method is well suited to forming screws that are of alloyed metal, where the cutting speed must be made suitable to the alloy. It is not adapted to very small screws, but is admirable for cutting worms or other very broad threads.

The familiar types of screw are named from the thing to which they are attached, as bench-screw, a coarse screw on a carpenter's bench for clamping the work; from the form or shape of the head, as square, hexagonal, round, conical, countersunk screw, etc.; from the character of the thread, as standard V, double (having two parallel threads running together), triple, etc. A winged or thumbscrew has a flat head that may be turned with the thumb and fingers; the Archimedian screw is a spiraled trough or tube which when laid at an angle of about 35 degrees, with the lower end in water, can be made to raise the water by turning; the differential screw has two different threads on one solid body, so that its ultimate motion is the difference between the pitch of the two threads; flat-screw, a spiral on the face of a disc, as a Victor record; interrupted screw, one having grooves cut longitudinally with threads like a tap; screw-coupling, a pipe coupling or metal collar with interior or female threads for joining pipes or round rods; screw-dog, a lathe-dog having a screw for gripping the work; screw-eye, a screw having a loop or eye for a head — when made with a hook it is a screw-hook; screw-plate, the holder of a die-stock; screw-press, a press in which the power is applied by a screw, as the primitive form of printing press; screw-rod, a rod having a screw-thread cut on one or both ends; screw-wrench, any wrench whose jaw is moved by a screw; tractor-screw, the screw-propellor of an aeroplane when placed in front as a tractor.

In 1929 there were 254 establishments devoted to the manufacture of machine-screw products and wood screws. The number of employees (average for the year) was 18,749, and the wages paid were $26,802,152. The cost of materials was $37,751,098. The value of products of the machine-screw manufacturers was $73,540,131, and of the wood screw, $9,726,556. Probably this is less than half the production of the entire country, as very many machine manufacturers make their own screws.

CHARLES H. COCHRANE,
Author of 'Modern Industrial Progress.'

SCREW-PINE, a popular name for species of *Pandanus,* order *Pandanaceæ.* The species of which more than 50 have been described, are natives of the tropics, and are especially numerous in the Australasian Archipelago. They are mostly trees or shrubs with slender or stout trunks, frequently with aerial roots. Each naked branch is terminated by a tuft of long sword-shaped spiny-edged leaves. In tropical countries *P. utilis* is highly valued for its edible fruits, and the fibres of its roots and leaves. The leaves of *P. odoratissimus* also yield a valuable fibre (q.v.). The former species, which has green leaves, and *P. veitchii,* which has variegated foliage, are widely popular in greenhouses, being easy to rear, fairly rapid in growth, and striking in appearance. The name screw-pine is suggested by the perfect spiral arrangement of the leaves easily observed in mature specimens, and also from their resemblance to the pineapple.

SCREW PROPELLER, a mechanical device embodying the principle of the screw, employed in the propulsion of various kinds of marine craft — ocean steamships, warships, tugboats, yachts, motor-boats, etc.— and all forms of aircraft. Only the marine form will be treated here: for the air propeller see AEROPLANE — CONSTRUCTIONAL FEATURES.

The marine propeller consists of a cylindrical or spherical hub or boss to which two or more blades are attached with bolts, and forms the screw which acts in the water somewhat like a screw bolt in a nut and the rapid rotation of which around its axis pushes the vessel forward.

It is the accepted modern method of ship propulsion and although known to waste at least 40 per cent of the power delivered to it by the driving engines, it has almost completely superseded the paddlewheel and confined the application of the latter to river steamers and other light draft craft.

Although known in principle to the ancients, and suggested in France by Bernouille in 1752, by Edward Shorter in 1800, and by Dallery in 1803, the credit for its modern reinvention and practical application appears to belong to Ressel, the Austrian inventor, who took out a patent for it in 1812 and used it practically on the steamer *Civetta,* in 1829. The idea was further developed by Sauvage in 1832, and a few years later, in England, by Smith and Ericsson. Smith's modification — the reduction in the number of blades, was suggested by an accident which broke off one of the six blades in his propeller, resulting in a decidedly accelerated motion of the vessel.

In America, Evans and Fitch experimented with screw propellers in 1780 and 1790, and Stevens successfully operated a steamboat equipped with a screw propeller, in 1802, but it was most practically developed and applied by Ericsson in 1839, in connection with the United States steamer *Princeton* which was the first screw-propelled war vessel ever built in any country. She was built through the recommendation of Commodore Stockton, under

Ericsson's personal superintendence. She had a tonnage of about a thousand tons, and was the first war vessel in which the machinery was entirely below the water-line, and her unqualified success not only demonstrated the particular value of the screw for vessels of war, but quickly led to its general application to those of the merchant service as well, before the close of the year 1870.

Each blade of a screw propeller may be considered as the small portion of a complete screw-thread of great pitch, and considerable depth relative to the pitch. The pitch of a propeller is the distance through which a point on the tip of one of the blades would move — in one revolution, assuming the water in which it turns to be a solid medium. As the water is not solid, but gives way as soon as its low degree of inertia is overcome, the shape given to the blade is not that of the true helical screw, but is so modified as to give it the firmest possible grip on the yielding water. There are two general types — (1) those in which the blades are plain warped surfaces, and the pitch is constant at all points, that is, the generating line of every blade keeps the same angle with the boss, and (2) those in which the blades are curved and bent in various ways, and the pitch is variable at different parts of the blades. Many different screws of this type, with variable or increasing pitch, have been designed in the attempt to produce a form that would reduce to a minimum the loss of applied power due to the rotary motion of the screw which forces the water away radially and the loss due to the friction of the blades. In the earlier forms, in which the boss was of small diameter — about twice that of the shaft — the increasing angle of the blade surfaces, as they approached the axis, placed them at the boss in a position parallel to the keel, so that the central portion of the screw gave very little propulsive efficiency — a great deal of the power being used up merely in churning and agitating the water. Another cause that wasted a great deal of energy was the number and length of the blades, and their great width at the ends, all of which absorbed power by surface friction.

To obviate these faults, Griffiths substituted for the central portion a large spherical boss, one-third the diameter of the whole propeller, which revolved smoothly in the water. He also diminished the width of the blades, and attached them to the boss in such a manner that they could be turned upon their axes and thus given various inclinations according to the speed intended for the ship. In the latest types of propellers, the diameter of the boss varies from one-fifth to one-third of that of the whole screw; while the diameter of the whole screw depends upon the speed required, the character of the driving machinery, the form of the ship, and many other conditions for which only approximate rules can be given. It is interesting and valuable to note in this connection, that upon the basis of the data derived from the actual tests of a great variety of screw propellers it is safe to state that the exact effect due to the form of their blades has not as yet been definitely determined, and that the shape of the hull of the vessel is by far the chief controlling factor in determining the question of speed. Another factor which adds greatly to the loss of applied power is the «slip» resulting from the working of the screw in a yielding or fluid medium and, therefore, requiring a greater number of revolutions to travel a given distance than would be required if it worked in a solid medium. Slip is a factor which adds greatly to the waste of applied power in all forms of propellers — sails, oars, paddlewheels, etc. In the case of the screw propeller, the difference between the distance traveled by the screw in a fluid, and the interval of its advance in a solid medium is known as the «apparent slip»; while the backward velocity given to the water immediately acted upon by the screw, is called the «real slip.» Both of these results are consequences necessitated by the working of a screw in a fluid medium, and may under certain circumstances vary considerably from each other. «Negative slip» is a term used to denote the actual speed of a ship above its calculated speed, very often attained by a change of the size or form of the propellor. Real slip may be expressed by the formula $\frac{v+f-s}{v}$, in which (v) represents the speed of the screw, (s) the speed of the vessel, and (f) the velocity of the forward motion of the water following in the wake of the vessel. The factor (f), being due to the frictional resistance of the vessel, depends so much upon the shape of its hull, that it is not susceptible of accurate determination, so that in considering the loss of applied power in this connection, the result ordinarily referred to is the apparent slip.

The speed of propeller is expressed by multiplying the number of its revolutions per minute by its pitch. This expression gives the theoretical speed per minute. The slip being subtracted from this gives the actual or effective speed. If the vessel were moored to a dock while the screw was running, the entire speed would be nullified by the slip.

The efficiency of different forms of propellers differs but slightly so long as their pitch, and their blade areas are designed correctly to suit the conditions for which they are employed. In general three-bladed propellers are the most efficient and are freer from vibrations than the other forms. As previously stated, however, the most important element affecting the propulsive efficiency of a screw propeller is the form of the vessel. For low speeds, bluff bows and full sterns gives results equally as good as sharp bows and lean sterns with a long hollow run; while on the other hand the last-named qualifications give a form that allows the waves of replacement to flow in solidly to the propeller, and is the most appropriate for high speeds. In general it may be said that the problem of the most efficient propeller for any given ship depends upon the speed at which the ship is intended to be driven. This being decided, the hull must be modeled in such lines that the water pushed to either side by the passage of the vessel shall have ample time and room to come solidly together again before the propeller begins to work in it. Hence, the slower the speed the fuller the stern may be modeled; and the higher the speed, the finer the lines of the stern approaching the propeller. Upon the

modeling of the hull, therefore, depends the speed of the engines. If the propeller is turned too fast for the possible speed of the model through the water it will simply churn the water (in part) to foam, at a great loss of efficiency. So that the number of revolutions of the screw per minute is actually determined by the shape of the hull, and its consequent resistance to motion through water. A slow moving screw may have narrower and longer blades, thus reducing the friction of the blade surfaces on the water, and in this way making for efficiency of the power delivered by the engine. And a slow moving screw may also have a greater pitch than a fast running screw, and this also tends to increase efficiency. The most satisfactory slow propellers (those on merchant ships) have a pitch of 1.2 to 1.5 times the diameter of the screw. On the contrary, the fast screws on passenger ships and war vessels, particularly those run by turbine engines, have a pitch of less than their diameter, and broad squat blades. Broadening the tip of the propeller blade increases the thrust, but slows down its speed. Conversely, the slow engine admits of a propeller of larger diameter, and with wider tips; and the efficiency of engines is greater at moderate speeds. So that the problem of the propeller depends upon the skilful balancing of many requirements and each must be given its weight in the compromise to achieve the best possible result.

Figs. 1 to 8 show a few of the 150 forms of screw propellers, designed at different periods, and illustrate in a general way its development from the primitive form designed by Ressel in 1812. All of those used at the present time,

FIG. 1.—Ressel-1812.

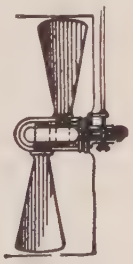


FIG. 2.—Ressel-improved.

however, are modifications of the Griffiths, Thornycroft, and Jarrow types. The Hirsch propeller has not come into general use for shipping, although in all trials it has shown an

FIG. 3.
Ericsson — 1835.

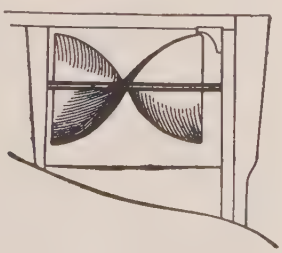

FIG. 4.
Maudslay — 1848.

efficiency from 3 to 8 per cent higher than the other types. It has, however, been largely adopted for motor-boats and small yachts and speed boats, and there are numerous modifications of it under various trade names. The so-called «weedless» propellers are on Hirsch lines.

Propellers are built of iron, steel or bronze. The last named is the preferred material and while there are as many formulas as there are

manufacturers, they may be classified generally under four groups: (1) Admiralty bronze, with a composition of about 87 per cent copper; 8 per cent tin; 5 per cent zinc; and with a strength of 15 tons to the square inch; (2)

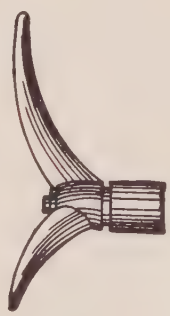

FIG. 7.
Jarrow — 1880.

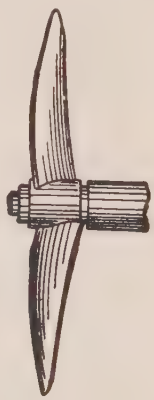

FIG. 8
Thornycroft — 1885.

phosphor bronze, 82.2 per cent copper; 12.95 per cent tin; 4.28 per cent lead; 0.52 per cent phosphorus; and with a strength of 17 tons per square inch; (3) aluminum bronze, 95 per cent copper and 5 per cent aluminum; with a strength of 25 tons per square inch; and (4) manganese bronze, of secret composition, except that it contains both copper and zinc, and has a strength of 30 tons per square inch. The cast iron or cast steel propellers of the slow-going merchant ships have a strength of from 10 to 20 tons per square inch. This would not be safe for a fast running propeller. The blades are cast solid with the boss, or made separate and bolted or attached to it in various ways. For small boats a reversible propeller is made in such fashion that the pitch of the blades may be altered from right-hand to left-hand by moving a lever working through a hollow propeller shaft, thus reversing the direction of the thrust without reversing the engine. A screw propeller when in position is secured to the end of the shaft of bronze or steel called the propeller or tail shaft, which is connected to the line shafting attached to the crank shaft of the driving engine. The push

or thrust of the screw, which is equivalent to the resistance of the hull, and amounts to about 20,000 pounds per 1,000 horse power, is received on a thrust bearing provided with a series of collars and grooves which fit similar ones on the shaft. Small vessels, and those designed for slow speed, are usually equipped with single screws; but for large high speed vessels, twin screws placed horizontally at right angles to the keel, one on each side of the stern post, are the most efficient. Some vessels have been fitted with three screws, but the amount of additional efficiency derived from the arrangement is a very doubtful quantity. On the other hand, high-powered vessels equipped with turbine engines employ multiple screws, the engines operating two, three or more shafts, with the advantage of dividing the work of generating the enormous power required by large modern ships among several small engines instead of one large ponderous machine, thus reducing to a minimum the difficulties and dangers incident to breakdowns. Sailing vessels using steam only as an auxiliary power are equipped with «feathering» screws, the blades of which can be closed together in a line parallel with the keel, and thus prevent them from acting as a drag when the vessel is propelled by the sails alone.

Fig. 9 shows the stern of the United States cruiser *New York* with twin screws in position.

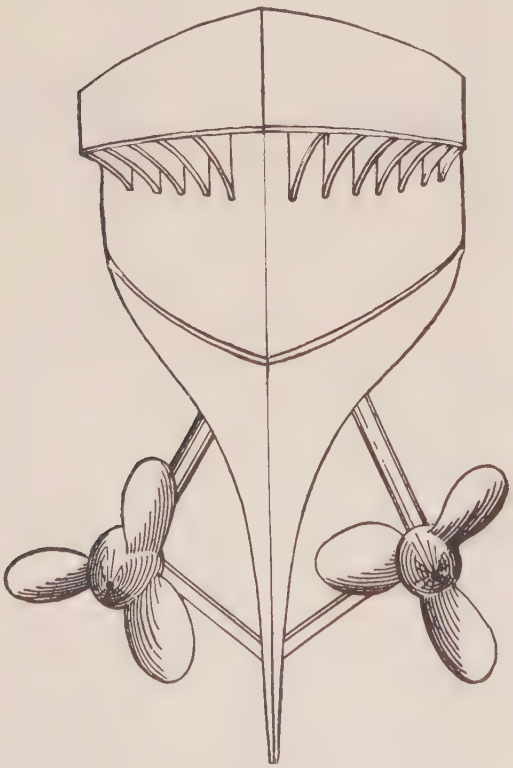

Fig. 9.—Twin Propellers, U. S. S. *New York*.

W., 'Screw Propellers and Estimation of Power for Propulsion of Ships' (New York 1913); Peabody, C. H., 'Propellers' (New York 1912); Seaton, A. E., 'The Screw Propeller and Other Competing Instruments of Marine Propulsion' (London 1909).

SCREW-WORM FLY, one of the fleshflies (q.v.) most troublesome to domestic animals in the southwestern United States. It lays its eggs in wounds, and the twisted larvæ feed and move in the flesh, making a bad sore.

SCRIABIN, skrĭ'ä-bēn, **Alexander,** Russian composer: b. Moscow, 10 Jan. 1872; d. there, 1915. In early life he was trained for a military career, but entered the Moscow Conservatory where he studied piano under Safonov and composition with Taneiev. In 1892 he won the gold medal for piano playing and during European tours achieved fame as a virtuoso. During 1898–1903 he was professor in the Moscow Conservatory, then resigned and devoted his energies to composition. Chopinesque yet original, his early piano pieces are marked by fervid spirituality, which led him after 1900 to formulate a synchronous theory of music, color and perfume which he sought to prove by means of his «color keyboard,» and his symphonic work 'Prometheus or Poem of Fire.' His other works include a piano concerto and four symphonies.

SCRIBE, skrēb, **Augustin Eugène,** French dramatist: b. Paris, 24 Dec. 1791; d. there, 20 Feb. 1861. He was originally intended for the legal profession, but early abandoned it for the more congenial occupation of a writer for the stage, in which after a careful study of the public taste his success was very decided. His first piece was 'Les dervis,' written in conjunction with his friend Germain Delavigne, and produced in 1811. Scribe's dramatic pieces comprise all the departments of the lighter kind of drama, and from their gaiety and interest of plot, as well as the felicitous manner in which modern French life is depicted, have acquired a universal popularity in Europe, and have also been introduced on the English stage in translations. Among his vaudevilles may be mentioned 'Le comte Ory,' 'Le nouveau pourceaugnac' and 'Une visite à Bedlam.' He wrote for the Odéon, the Porte Saint Martin, and the Variétés theatres, but more especially for the Gymnase Dramatique, to which he furnished 'La maîtresse du logis'; 'Malvina ou un mariage d'inclination'; 'Le mariage de raison'; 'Geneviève, ou la jalousie paternelle'; 'Maître Jean, ou la comédie à la cour'; 'L'Amitié, ou les trois epoques'; 'Héloise et Abélard'; and numerous other pieces. To the Théâtre Français he contributed 'Bertrand et Raton' (1833); 'Le verre d'eau' (1840); 'Adrienne Lecouvreur' (1849) and 'Les contes de la reine de Navarre' (1850). In collaboration with Legouvé he wrote 'Bataille des dames' (1851) and 'Les doigts de fée' (1858). As a writer of opera librettos Scribe is also deservedly famous, having supplied composers with the text of the most celebrated of those produced at the Grand Opera and Opera Comique. Of these mention may be made of 'La dame blanche' (1825); 'Fra Diavolo' (1830); 'Robert le Diable (1831); 'La juive' (1835); 'Les huguenots' (1836); 'Les diamants de la couronne': 'Les martyrs' and 'Le prophète' (1849). From the multiplicity of works with which he was engaged, Scribe, like other French authors, availed himself largely of the assistance of collaborateurs, and much,

therefore, which bears his name was in reality only subjected to his revision and superintendence. In 1836 he was admitted a member of the French Academy.

SCRIBE, The, an early Egyptian statue now in the Louvre Museum, Paris. Colored red, and with inlaid eyes of crystal, it is regarded as one of the most characteristic illustrations of the art of the fifth dynasty.

SCRIBES, Jewish. Originally nothing more than copyists of the law, a business which they followed as a means of livelihood, the Jewish scribes gradually increased the importance of their position until, after the dissolution of the commonwealth, they became the vital force which determined the later form of Judaism. The importance of their office as doctors of the law and interpreters of the Scriptures is shown in many passages in the Old and New Testament. During this rise in the influence of the Jewish doctors they were known by five distinct appellations: (1) the Sopherim, or «Scribes.» who guarded the Bible against corruption and who read the law; (2) the Tanaim, or teachers of the law; (3) the Amoraim, or doctors of the law; (4) the Saboraim, or teachers of the law after the conclusion of the Talmud; (5) the Gaonin, or last doctors of the law in the chain of rabbinic succession, the latter title being applied to the presidents of the colleges, which when assembled together explained difficult points in the Talmud, discussed and answered all ritual questions and enacted new laws for the regulation of the dispersed congregations.

SCRIBLERUS CLUB, The, a club organized by Swift in 1714. An association of writers, its object was the suppression of exhibitions of literary incompetence by means of satire. Pope, Gay, Bolingbroke and other authors of that day were prominent as members.

SCRIBNER, skrĭb'nẽr, **Charles**, American publisher: b. New York, 21 Feb. 1821; d. Lucerne, Switzerland, 26 Aug. 1871. He was graduated from Princeton in 1840, and in 1846 established with Isaac D. Baker the publishing house of Baker and Scribner, which after the death of his partner in 1850 became known as that of Charles Scribner and Company. *Scribner's Magazine*, founded by this firm in 1870, was purchased by other publishers and became the *Century Magazine* in 1881. A new *Scribner's Magazine* was established by the firm, known since the death of its founder as Charles Scribner's Sons, in 1887.

SCRIBNER, Frank Kimball, American author: b. New York, 22 Feb. 1866. He was graduated from Williams College in 1890, studied at Harvard Law School, engaged in literary work since 1903 and was for four years on staff of the New York *Sun*. He has contributed articles to current publications and has had published series of hunting and fishing stories, 'The Honor of a Princess' (1897); 'The Love of the Princess Alice' (1898); 'The Fifth of November' (1898); 'A Continental Cavalier' (1900); 'The Red Lion'; 'The Ravens of the Rhine'; 'The Secret of Frontellac.' He is a member of the Author's League of America, the Williams Club, the National Geographic Society, American Forestry Association and the Social Science Club.

SCRIBNER, Frank Lamson. See LAMSON-SCRIBNER.

SCRIP, *in commerce*, a term commonly used for a certificate of loans or shares in a joint-stock company, whether as a temporary acknowledgment or the permanent voucher of the holder's interest. Script may accordingly be either transferable or not transferable. The valid transfer of interest may be effected only by registration in the books of the company, or the transfer of the scrip itself may be held to represent a valid transfer of interest. *In heraldry*, a bearing representing a pouch or almoner. The word also means a scrap of paper or parchment usually with some writing on it, and during and after the Civil War in America was applied to the fractional paper money issued by the government of the United States.

SCRIPTURE, skrĭp'tūr, **Edward Wheeler**, American psychologist: b. Mason, N. H., 21 May 1864. He was graduated from the College of the City of New York in 1884. After pursuing his psychological investigations at the universities of Berlin, Leipzig and Zürich, he was called to Yale, where he became director of the psychological laboratory in 1898. In 1902 he became assistant professor of psychology there and four years later was made lecturer at Johns Hopkins. In 1909 he became lecturer on psychiatry at Columbia. Later he became professor of experimental phonetics in the University of Vienna. He was the discoverer of a method of measuring hallucinations and processes of imagination, and the originator of a method of producing insensibility by means of electricity. He was also the discoverer of the law of the «mediate association of ideas.» His writings include 'Thinking, Feeling and Doing' (1897; 2d ed., 1907); 'The New Psychology' (1898; 2d ed., 1905); 'The Elements of Experimental Phonetics' (1902); 'Researches in Experimental Phonetics' (1906); 'Study of English Speech by New Methods of Phonetic Investigation' (New York 1923); 'Stuttering, Lisping and Correction of the Speech of the Deaf' (New York 1923).

SCRIVENER, skrĭv'nẽr, **Frederick Henry Ambrose**, English Biblical scholar: b. Bermondsey, London, 29 Sept. 1813; d. Hendon, 26 Oct. 1891. He was educated at Trinity College, Cambridge, and from 1846 to 1856 was headmaster of Falmouth School and incumbent of Penwerris, retaining this living till in 1862 he was presented to the rectory of Gerrans, Cornwall. In 1870 he was appointed a member of the New Testament Revision Company, and in 1872 was granted a pension from the civil list in recognition of his services in connection with Biblical criticism. In 1875 he became vicar of Hendon, Middlesex, and prebendary of Exeter. He took high rank in the philological criticism of the New Testament, on which he published some valuable works, beginning with an edition of the Greek text in 1858, executed after collating about a score of unexamined manuscripts. His chief work was his 'Plain Introduction to the Criticism of the New Testament' (1861). He also published 'Cambridge Paragraph Bible' (1873) and 'Bezæ Codex Cantabrigiensis,' etc.

SCROFULA, a diseased state of the body characterized by usually indolent cheesy glan-

dular tumors which suppurate and imperfectly heal, leaving fistulous passages or ugly scars. It is also known as struma, scrofulosis, tuberculous adenitis and tuberculosis of the lymphatic system. It is a mild grade of tuberculous infection and should be treated as such. Sometimes internal organs, especially bones and joints, are attacked by a low grade of inflammation followed by a caseous degeneration. Scrofula was common in ancient and medieval times. It was formerly called king's evil, and for centuries was treated by the touch of the kings of England and France. Modern medicine does not recognize any disease as scrofula.

SCROGGS, skrŏgz, Sir **William,** English jurist: b. Deddington, Oxfordshire, England, about 1623; d. London, Oct. 25, 1683. His name is a synonym for judicial injustice and cruelty. He was appointed chief justice in 1678 in which office his brutal methods and infamous partiality in conducting the trial of the victims of Titus Oates' antipopish conspiracies, soon made him notorious. He was impeached by the House of Commons in 1680 but was never tried. However, in 1681 he was removed from his office by the king, who granted him a pension.

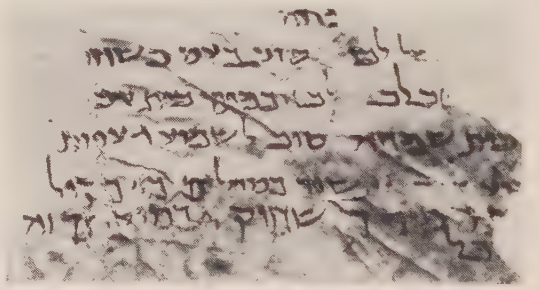
SCROLL, skrōl. The word is derived through the Middle English from the Old French *escroelle, escroele,* meaning a strip or roll; hence a roll or bundle of paper or parchment containing writing. The larger number of ancient Biblical documents were inscribed on leather, parchment, or vellum. The skins were sewn together in long strips, and after being inscribed were formed into scrolls. Compare the Hebrew Megilloth or rolls, such as the five books of Ruth, Esther, Canticle of Canticles (Song of Songs), Ecclesiastes, and Lamentation. The word scroll is also applied to a wide class of ornaments, etc., with spiral designs of various sorts, or to the flourish appended to a signature.

SCROLLS, The Dead Sea. In the spring of 1947 a member of the Ta'amireh tribe of Bedouins discovered a number of ancient scrolls in a cave in the cliffs west of the Dead Sea, some seven miles south of modern Jericho.

The 11 scrolls represent seven independent works. The first of these is a complete Book of Isaiah, containing 54 columns. The orthography is notable for its profuse use of the vowel letters. While there are a number of variants, some of which agree with the Septuagint and other versions, the most striking feature of the scroll is its close approximation to the Masoretic text. The manuscript is carelessly written, containing a number of omissions, but these have been remedied by marginal and supralinear insertions. The complete text, together with that of the Habakkuk commentary, mentioned below, was published in 1950 by the American Schools of Oriental Research, and edited by Millar Burrows of Yale University (*The Dead Sea Scrolls of St. Mark's Monastery,* vol. 1). It gives a facsimile of each column together with the transcription of the Hebrew on the opposite page.

The second work, containing 11 columns of text, is a composition of a Jewish sect and is known as the Manual of Discipline. It is the most important of the non-Biblical writings. It gives the impression of being a compilation of several originally separate documents. The life and order of the community are described in great detail. The community is dedicated to a life of obedience and service to God, "to do what is good and right before Him, as he commanded through Moses and through all his servants the prophets." The annual ceremony of entrance into the covenant is described, and the statutes and regulations governing daily conduct, especially for the meetings of the holy assembly, are given in great detail. The most characteristic words are *truth, faithfulness, holiness, perfection, knowledge, community,* and *covenant.* While the greater part of the work is legalistic, the last two or three columns, in poetic form, are confessional and devotional in character and, in striking contrast, appeal to justification through God's righteousness.

The third scroll, with a little more than 12 columns, contains a commentary of the first two chapters of the Book of Habakkuk. The writer quotes a small portion of the Biblical text, and follows it with the formula, "This means" or "Its meaning is." The commentary reflects the writer's own times; it is, therefore, the most important of the scrolls for our knowledge of the history of the period. Unfortunately the allusions are obscure. Many attempts have been made to identify "the teacher of righteousness" and "the wicked priest" or "the man of lies," but no proposed solution has yet found general support. The scroll is superbly written and obviously the work of a skilful scribe.



© Palestine Archaeological Museum

A beautifully written fragment from the Book of Ecclesiastes, dating from about the middle of the second century B.C.

The fourth scroll, originally believed to be the lost Apocalypse of Lamech and to be written in Aramaic, is now known to be a paraphrase and commentary on the Book of Genesis in Hebrew and Aramaic. These four scrolls together with those still to be discussed are deposited at the Hebrew University in Jerusalem.

Among the scrolls originally published by E. L. Sukenik of the Hebrew University the first is an incomplete Isaiah (chaps. 38-66 with parts of chap. 10 in fragments). It follows the Masoretic text much more closely than the first scroll, and therefore has special interest for the transmission and history of the text. It has been published under the title (in Hebrew) of *Library of the Hidden Scrolls,* by the Bialik Foundation in Jerusalem, together with the other books named below.

The War of the Sons of Light and the Sons of Darkness is preserved almost in its entirety. It contains 19 columns, and describes in vivid detail an eschatological war, reminding one of the conflict of Gog and Magog in the Book of Ezekiel and of the final conflict described in the

Book of Revelation. The description of the battle formations with their standards, bearing sacred legends like "The Truth of God," "The Glory of God," and "The Justice of God"; the inscribed trumpets of various military divisions, and of the military tactics and strategy, have been clarified by the study of contemporary Roman practices.

The last work, now in four separate scrolls with 12 columns of text, was originally a collection of 20 psalms, and is known as the Hodayoth or thanksgiving hymns. They not infrequently remind one of the Hebrew Psalter, but their stylistic affinities are closer to some of the psalms of the intertestamental period, such as the Psalms of Solomon, and to the nativity hymns of the Gospel of Luke.

In addition to the foregoing scrolls a substantial number of fragments have been recovered from Cave 1. These have been published in *Discoveries of the Judean Desert* by D. Barthélemy and J. T. Milik, vol. 1. Besides a number of Biblical texts, they contain fragments of commentaries on the books of Micah, Zephaniah, and Psalms; pseudepigraphical writings like Jubilees, the Testament of Levi, and a Book of Mysteries; liturgical works with a collection of benedictions, hymns, and prayers; and finally the extraordinary "Rule of the Congregation" in two columns, which opens with the words, "Now this is the order for the whole congregation of Israel in the latter days."

Date of the Scrolls.—Several independent lines of evidence converge upon a period from the 2d century B.C. to the Jewish War (66–70 A.D.), more precisely 68 A.D. Among these the more important are the paleographical, that is, the witness of the handwriting; the archaeological, especially the ceramic evidence gathered from the pottery of the caves and of Khirbet Qumrân; the witness of the coins, or numismatic evidence, which in one significant cache terminated c.68 A.D.; the historical allusions, though these are admittedly unclear; the literary relationships; the orthography, vocabulary, and syntax; the Carbon 14 test, yielding a date of 33 A.D. with a margin of plus or minus 200 years. No one of these witnesses can be said to be in itself decisive, but together they constitute a strong bulwark for an early date.

Excavations at Khirbet Qumrân.—This ancient ruin lies about a kilometer to the south of Cave 1. It has been excavated by Father Roland de Vaux, the head of the French Dominican School of St. Stephen in Jerusalem (Jordan), and G. Lankester Harding, Director of Antiquities for the Hashemite Kingdom of Jordan. It has been demonstrated that the ruin is contemporary with the writing of the scrolls. Cisterns have been exposed, some of which *may* be related to the references to ceremonial ablutions or baptisms described in the Manual of Discipline. In one room (40 feet by 12 feet) benches, desks, an ablution bowl, and two inkwells containing dry ink were discovered. This was in all probability the place where the scrolls were copied. More interesting was a large room, the place where the sacred meals were celebrated. Nearby some 1,100 bowls and other "dishes" were found, more than 600 of them unbroken. Five campaigns have thus far (1956) been carried on at Khirbet Qumrân. The results have served to supplement much of what we learn from the Manual.

Identification of the Community.—But who were the holy men who lived on the shores of the Dead Sea from the 2d century B.C. to the destruction of the community c.68 A.D.? The question is obviously one of great importance. Now the Roman historian Pliny, writing c.77 A.D., tells of "the solitary tribe of Essenes" living on "the west side of the Dead Sea," and the Jewish historian, Flavius Josephus, writing in the 1st century of the Christian era, devotes a long section of his *Wars* (II, viii, 2-14) to the Essenes. These reports are amplified by a number of references in the works of Philo of Alexandria (*Quod omnis probus liber sit; De Vita contemplativa; Hypotheteca*). There are many striking parallels between Josephus' account of the Essenes with the Manual of Discipline, and this is true also, though to a lesser degree perhaps, of Philo. While absolute certainty on the question of identification is precluded, it can be said with considerable confidence that the Qumrân sect must have been very similar to the Essenes, if, indeed, they were not the Essenes.

Discovery of the Fragments.—In the spring of 1952 announcement was made of the discovery of many more scrolls by the Ta'amireh bedu. By far the richest "find" came from Cave 4, the most impressive of all the caves, located, as it is, high up on the face of a cliff at the juncture of two wadies. This cave alone contained fragments of well over 300 separate scrolls. About one third of them are Biblical, every book in the Old Testament being represented with the exception of the Book of Esther. Deuteronomy, Isaiah, and Psalms are represented most frequently. Among the extra-Biblical writings only the following can be mentioned here: a messianic florilegium, a catena of passages from the Hexateuch and containing the crucial verse, Deuteronomy 18:18, concerning the coming prophet; fragments of the Zadokite Work, certainly the composition of the same community; fragments of an Aramaic Enoch and of a Hebrew and an Aramaic Tobit; several commentaries; and liturgical works.

Significance of the Scrolls.—(1) The Biblical scrolls antedate our earliest extant Hebrew text by about 1,000 years. This by no means suggests that the text is superior to the Masoretic text. On the contrary the latter can generally be safely maintained. But this does not dispose of the matter. Not a few of the variants in the first Isaiah scroll have a claim to be considered. Moreover, extensive fragments from I and II Samuel, representing the Hebrew prototype or Vorlage of the Septuagint, have appeared. Since the Masoretic text of these books is notoriously corrupt, and the Septuagint often gives us a superior witness, these materials are of great importance. A line fallen out of our Hebrew text of Deuteronomy 32:43, but preserved for us in Hebrews 1:6 and the Septuagint, has been recovered in a Hebrew text. Finally, it is to be observed that we now have evidence of a Masoretic tradition long before the rabbinic recension of 100 A.D., a recension which destroyed all variant textual traditions.

(2) The scrolls have importance for our knowledge of the history, literature, and religion of the intertestamental period. The Essenes (?) were, to be sure, a sectarian group, but it can no longer be doubted that they occupied a position of far greater importance than we have assumed in recent years. The question of the authorship of the books of the Apocrypha and pseudepigrapha will now have to be reconsidered. The Zadokite work was *certainly* Essene (?), and Jubilees, Enoch, the Testaments of the Twelve Patriarchs,

and the Assumption of Moses probably belong to the same group. The apocalyptic world view of the community is strongly marked, but there are other strands of thought too; that is, legalism, prophetic theology and ethics, wisdom, and mystical piety.

(3) The holy men of this ancient sect thought of themselves as "the new covenant" that is, New Testament. They went into the desert in literal fulfillment of the words of Second Isaiah (40–66), "In the wilderness prepare the way of the Lord, make straight his paths," though they interpreted this as meaning the devout study of the law, which, indeed, they pursued day and night. It is significant that the ministry of John the Baptist opens with these words in all four of our Gospels. John came baptizing in the wilderness of Judea in the region of the Jordan, in all likelihood in the very region of our holy community. The affinities between John and the Essenes (?) are so numerous and striking that some scholars have thought of him as at one time a member of the community; while this cannot be demonstrated, the possibility cannot be excluded. The question "Are you the prophet?" would have very special relevance for the sect. The rite of "baptism," the emphasis upon repentance and the Spirit, the message of judgment and doom, all this belongs to the same climate as that at Qumrân.

(4) The affinities between the Dead Sea Scrolls and the New Testament have received much attention by scholars. Most striking is the relationship of the Manual to the Gospel of John. The conflict between light and darkness and between life and death, is common to both, and John's words about the relation of the *logos* to creation in the prologue are not unlike a passage in the Manual. The Semitic character of John has been rendered more probable.

(5) The two central rites of the sect of the "new covenant" were baptism and the communion meal. The former was not an act once for all, but was practiced periodically, perhaps annually, at each celebration of the renewal of the covenant. The latter is described in a remarkable passage in the "Rule of the Community" in two columns. Here we have an eschatological celebration; the messiahs play a central role; the participants are seated according to rank at the table of communion; the presiding priest blesses the wine and the bread.

(6) In the ritual of the communion the messiahs of Aaron and Israel are mentioned, but elsewhere we read (in the Manual of Discipline) of "the coming of the prophet and the messiahs of Aaron and Israel." In the New Testament each of these titles, prophetic, priestly, and royal, are referred to Jesus, but never together. In later Christian thought the association of all three is made, however. This influence upon the early Christian community is by no means isolated. In such early Christian writings as the Didache and the Epistle of Barnabas, we encounter a number of striking parallels to the Dead Sea Scrolls, more especially in the section on the Two Ways.

SCROOGE, Ebenezer, the leading character in Dickens' *Christmas Carol* (q.v.) and employer of Bob Cratchit, a poor clerk. Scrooge, "a squeezing, grasping, covetous old hunks, sharp and hard as flint," has visions of Christmases past, present, and to come. They have a miraculous effect on his nature, making him benevolent, cheerful, loving, and by all beloved.

SCROPHULARIACEAE. See FIGWORTS.

SCRUBBIRD, skrŭb'bûrd, any bird living in or frequenting bush or scrub; specifically a small bird of the abnormal passerine genus *Atrichornis* inhabiting bushy scrub in Australia.

SCUDDER, skŭd'ĕr, **Horace Elisha,** American author: b. Boston, Mass., Oct. 16, 1838; d. Cambridge, Jan. 11, 1902. He was graduated from Williams College in 1858, engaged as a teacher in New York for three years, and in 1867–1870 he edited *The Riverside Magazine for Young People.* He then entered business life, but soon withdrew to devote himself entirely to literature. His juvenile publications, which were widely popular, include *Seven Little People and their Friends* (1862); *The Bodley Books* (1875–1887); *The Book of Legends Told over Again* (1899). His work was not, however, confined to juvenile literature. He edited the *Atlantic Monthly* in 1890–1898, and contributed much to it, though usually anonymously; edited *The American Commonwealth Series; American Poems* (1879); *American Prose* (1880); and wrote *Life and Letters of David Coit Scudder, a Missionary in India* (1864); *Noah Webster, a Biography* (1882); *Men and Letters* (1887); *James Russell Lowell, a Biography* (1901).

SCUDDER, Janet, American sculptor and painter: b. Terre Haute, Ind., Oct. 27, 1873; d. New York, N. Y., June 9, 1940. She was educated at the Cincinnati Art Academy, the Art Institute, Chicago, and at the academies of Vittis and Colarossi in Paris, and at MacMonnie's Studio there. She lived abroad most of her life. She was awarded medals at the expositions at Chicago 1893; St. Louis 1904; Paris 1911 (honorable mention); San Francisco 1915; and Amsterdam 1928. She was made chevalier of the Legion of Honor in 1925. Her works include *The Frog Fountain* (Metropolitan Museum, New York City); *Young Diana* and *Little Lady of the Sea* (Paris Salon); *Fighting Boys Fountain* (Art Institute of Chicago); and others at the Luxembourg, Congressional Library, and Peabody Institute. She wrote *Modeling My Life* (1925).

SCUDDER, John Milton, American eclectic physician: b. Harrison, Ohio, Sept. 8, 1829; d. Daytona, Fla., Feb. 17, 1894. He was educated at Miami University, Oxford, Ohio, and was graduated in medicine at the Eclectic Medical Institute of Cincinnati, Ohio, in 1856. In 1857 he was appointed demonstrator of anatomy and served as professor of obstetrics and diseases of women in his alma mater, 1858–1860. From 1860 to 1887 he filled the chair of pathology and practice of medicine, and from 1887 to his death the chair of hygiene, principles of medicine, physical and specific diagnosis. In 1869 he published the doctrine of specific medication, originated by him, and since that time the basis of practice of the eclectic school of

medicine. For 32 years he was editor of the *Eclectic Medical Journal*, the oldest periodical devoted to American eclectic medicine. He wrote 'Practical Treatise on Diseases of Women' (1858); 'Eclectic Materia Medica and Therapeutics' (1860); 'The Eclectic Practice of Medicine' (1864); 'The Use of Inhalations' (1865); 'Domestic Medicine' (1866); 'The Principles of Medicine' (1867); 'Diseases of Children' (1867); 'Specific Medication' (1871); 'Reproductive Organs and Venereal Diseases' (1874); 'Specific Diagnosis' (1874). He was the most conspicuous eclectic physician of his time.

SCUDDER, Samuel Hubbard, American entomologist: b. Boston, Mass., 13 April 1837; d. 17 May 1911. He was graduated at Williams College in 1857 and at Harvard University in 1862. He was custodian of the Boston Society of Natural History in 1864–70, and was its president in 1880–87. He served as palæontologist on the United States Geological Survey in 1886–92. Author of 'A Century of Orthoptera' (1879); 'Butterflies' (1881); 'Fossil Insects of North America' (1890); 'American Fossil Cockroaches' (1895); 'Catalogue of the Described Orthoptera of the United States and Canada' (1900); 'Index to North American Orthoptera Described in the Eighteenth and Nineteenth Centuries' (1901), etc.

SCUDDER, Vida Dutton, American educator and author: b. Madura, India, 15 Dec. 1861. She was graduated from Smith College, Northampton, Mass., and studied at Oxford, England, and in Paris, France. She became connected with the formation of college settlements, was instructor in English literature at Wellesley College in 1887–92 and from 1892–1910 was associate professor when she became professor of that department. She is the author of 'How the Rain Sprites Were Freed' (1883); 'The Life of the Spirit in Modern English Poets' (1895); 'Social Ideas in English Letters' (1898); 'Introduction to the Study of English Literature' (1901); 'A Listener in Babel' (1903); 'The Disciple of a Saint' (1907); 'English Poems' (1915); 'Social Teachings of the Christian Year' (1921); 'Brother John' (1927).

SCUDÉRY, skü-dā-rē, or **SCUDERI, Madeleine de,** French writer: b. Havre, 15 Nov. 1607; d. Paris, 2 June 1701. She gives an account of her early life under the name of «Sapho,» the title assigned to her by her contemporaries, in her romance, 'Le grand Cyrus.' At 12, she says, she was spoken of as a person of mature judgment, and much admired. On coming to Paris she was admitted to the society of the Hôtel de Rambouillet, and began to assist her brother Georges, a writer of plays, romances and sonnets, in his literary labors. Her first romances were published in her brother's name, and he doubtless assisted in the formation of the plot, or at least suggested the plan of her works. The character of the works themselves is sufficiently explained by the circumstances of their production, but their protracted popularity is not so easy to understand. Her admirers range from Christina of Sweden to Mascaron, Fléchier and Massillon. Boileau himself did not dare to publish his satire during her lifetime. Her works may be regarded as a reflection of the society in which she moved. They consist chiefly of long romances replete with sentiments of love and gallantry; their predominant characteristic is affection.

The heroes of Mlle. Scudéry are the heroes of antiquity, Cyrus, Horatius Cocles, Mutius Scævola and Brutus. These and similar personages meet and discuss with appropriate heroines the anatomy of passion in endless conversations of the most refined subtlety.

The names of her characters were only a transparent mask behind which her readers saw and read themselves. The society of the Hôtel de Rambouillet furnished the originals for all the heroes of antiquity. Cyrus, it is well known, was the great Condé. The society of the day furnished her with endless materials and the gallantries of the preceding night formed the subject of the day's description. Thus with conversation, epistle, sonnet and madrigal she worked out a chronicle of petty intrigue under the greatest names of the world's history. After the reunions at the Hôtel de Rambouillet had been broken up by the troubles of the Fronde, Mlle. de Scudéry opened her own house to a select society on Saturday evenings. In this society, where everybody assumed a sentimental name, love was discussed, according to Mme. de Sévigné, in language so involved, that the speakers were ever in danger of being lost in their own mazes. The interminable conversations and meaningless gallantries which make her works dull at present were precisely what gave them interest when all her characters were known; and as she was admired and respected by those she portrayed, it is evident they were flattered by her portraits. Her principal works are 'Ibrahim, ou L'illustré Bassa' (1641); 'Artamène, ou le grand Cyrus' (1650); 'Clélie, histoire romaine' (1656). Besides these are numerous other romances, poems and 10 volumes of conversations and moral discussions. She obtained the prize in the first competition of the French Academy in eloquence for a 'Le discours de la gloire' (1671). See CLÉLIE.

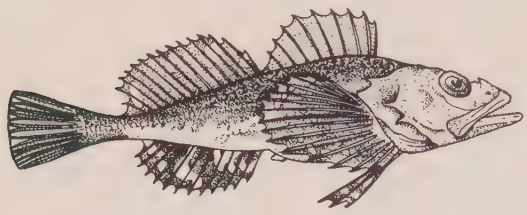
SCUDO, skoo'dō, an ancient Italian coin named from its bearing the impress of the heraldic shield of the sovereign by whom it was issued. The scudo was of different value in different states and at different times. The recent value of the Italian scudo was about $1. The Roman scudo was of gold and worth about $16.

SCULLING. See ROWING.

SCULPINS, the name given to various species of spiny-rayed teleostomous fishes of the family *Cottidæ*, or to the members generally of that family. The sculpins are fishes of striking appearance owing to the peculiar manner in which the body tapers regularly backward from the large, depressed head, and the large size of the fins. The mouth is large, the eyes placed so that they look more or less upward, a bony rod runs across the cheek between the suborbital and the preopercular bones, and the bones of the head are ornamented in varied fashions with numerous ridges and spines. The skin is largely naked but is often provided along the lateral line and elsewhere with bony plates or spines. All of the fins, and especially the pectorals, are of large size and the latter has a remarkably extended base of attachment. The family is a large one, embracing more than 60 genera and 250 species. Most of the species

live in the northern seas among rocks in shallow water, but some remarkable forms live in deep water. Some small species inhabit fresh waters. All are of small or moderate size and are little used for food.

Among the numerous North American species the best known is the common or big sculpin (*Myoxocephalus groenlandicus*). This species reaches a length of two feet, but is usually smaller and is abundant in the North Atlantic, on the American side as far south as New York. In the far north it approaches the coast from the deeper water in summer, but on our shores is



Sculpin.

most plentiful during the winter spawning season. The eggs are laid in large masses attached to seaweeds or rocks.

Sculpins are exceedingly active and voracious and devour all kinds of animals dwelling on the bottom. The sea raven (*Hemitripterus americanus*) (q.v.) is another noteworthy member of this family. Of the freshwater sculpins the miller's thumbs (*Cottus*) are represented by numerous species of little fishes which dwell among stones in cold springs, brooks and lakes, laying their eggs in masses on the under side of stones and guarding them until hatched.

SCULPTURE is the art of shaping figures or organizing forms in three dimensions. Most commonly the shaping is achieved by carving, by modeling or by casting, though other procedures, for instance beating and welding, are also used. The materials employed are extremely varied and range from plastic, amorphous substances, such as clay, to the hardest of stones and metals. The techniques and processes of fashioning sculpture vary with the nature of the materials shaped.

Carving.—To the layman, carving is the most obvious method for producing sculpture. In a broad sense carving comprehends any means by which the sculptor can reduce a piece of material to the form desired by removing the superfluous portions. For this reason it is often called a subtractive process. In the carving of wood the sculptor will use tools similar to those used by carpenters or cabinetmakers, that is to say, saws, chisels, files, etc. Almost all kinds of wood have been used for sculpture, but generally the carver prefers evenly textured woods with little grain. Large wooden statues are made by gluing several pieces together. Some of the softer stones, for instance limestone when freshly quarried, may be carved about as easily as wood, and with similar tools. The preliminary shaping of a block of marble is done with a pick or with points (single pointed chisels). The generalized form is achieved with the use of claws (many pointed chisels) which leave fairly small parallel ridges on the surface of the marble. These ridges may be reduced with flat chisels and files, and the surface polished with abrasives. Drills are used on marble as well as other stones. Extremely hard stones like granite are generally worn down by repeatedly crushing the surface with a many-pointed hammer called the boucharde or bush-hammer.

Modeling.—Modeling is the making of sculpture from plastic, rather soft and yielding materials, such as clay or wax. While the sculpture so produced may occasionally be the complete work, usually it is intended to be translated into a more durable material. Clay, of course, may be baked to form terra cotta, which is as durable as tile or brick. When he prepares a large work for baking, the sculptor makes it hollow if it be in the round, or rather thin if it be in low relief, to insure thorough baking of the entire fabric and to avoid fracturing from sealed-in moisture, which under heat would literally explode.

Modeling is often called an additive process, signifying that the work is produced by adding piece by piece until the whole is built up. Thus it is distinguished from the subtractive procedure of carving. Actually, carving tools of wood and wire, suitable for the soft materials, are used in modeling to cut away or scoop out unwanted material. A more significant distinction between modeling and carving lies in the fact that the material of the modeler is amorphous and yielding with virtually no form except what the sculptor gives it. This is illustrated by the usual procedure of modeling in clay. First the sculptor visualizes quite clearly the completed work (often he makes drawings or small models for this purpose); then he constructs an armature (a kind of skeletonlike structure) of wire or pipes depending on the size of the work; and then he adds handsful of clay to the armature until he has built up the complete bulk of his statue. He finishes the modeling by manipulating the clay with his hands, by carving, and perhaps by producing some textural effects. While the procedure just described pertains to sculpture in the round, the same procedure with some variations applies also to work in relief, although in relief the structure to which the clay is added is a board rather than an armature.

Metal Techniques.—Repoussé is the technique of pushing, beating, or hammering quite malleable metals, such as copper, lead, and aluminum, into the form desired. Frequently the metal is beaten into shape over, or into, a form which has been produced by carving or casting. This is a handicraft reproductive process akin to the manufacturing process of stamping with dies. Twentieth century artists generally employ the freer technique of beating the metal into shape without the use of prepared forms.

Other metal techniques include the hammering into shape of metal (especially wrought iron) which has been softened by heating; and an additive process of constructing a work of sculpture with blobs of molten metal using welding equipment and materials. Both of these techniques are most used for small works since the products are apt to be solid and therefore very heavy for their size.

Reproductive Processes.—These have been, and still are, of great importance in the art of sculpture both for making replicas of originals and as a phase in the production of original works. When used for the latter purpose the artist should have had in mind from the beginning of his work the possibilities and limitations of the reproductive technique as well as the character of the

final material. The chief reproductive processes are casting and pointing.

Casting is the process of producing objects, or reproducing the form of objects, by putting into a mold a plastic or temporarily fluid material which will assume and retain the shape of the mold. Since casting is extensively used in industry, a great variety of techniques and materials have been developed for specific needs. Nearly all of these procedures and materials may be used for the casting of sculpture, however only a few are much employed by the sculptor.

The model of the work to be cast is usually produced by modeling a plastic earth or wax; however carved works will serve as well, and are frequently copied by casting. Indeed, the mold, or matrix, which has the negative form of the work to be produced, may be fashioned directly without the use of a positive model. This has seldom been done for sculpture and then usually for extremely simple works.

Molds may be made of flexible materials such as glue, gelatin, rubber or agar compositions, or they may be rigid of plaster of paris, terra-cotta, sand, metal, etc. Flexible molds, first developed about the middle of the 19th century, are especially useful for the casting of intricate forms with undercuttings. The older, traditional methods of casting employ rigid molds which may be either waste molds or piece molds.

A waste mold is a negative mold that will be fractured and destroyed in order to free the positive cast within it. A new mold must be made for each work produced. The major sculptural use of the waste mold is in the process of bronze casting known as *cire-perdu* (or lost-wax).

Benvenuto Cellini (1500–1571) described the lost-wax process which he used for the casting of his bronze relief *Nymph of Fontainebleau* and his statue *Perseus*. He began by modeling each work in fire-resistant clay over an armature. These he allowed to dry until they had shrunk about one half inch all around. Then he covered them with a coating of wax somewhat less than a half inch in thickness, which he carefully modeled and finished in every detail. For each work, over the wax he placed successive layers of fire-resistant clay until he had built up a heavy envelope, which was firmly attached by transverse bronze rods (used skewer fashion) through the layer of wax to the inner clay core. With the application of heat the wax was melted and drawn out through apertures left for that purpose, and when the core and envelope were thoroughly dried, the molten bronze was poured in so as to replace, and reproduce exactly, the form of the wax. When the outer envelope, or negative mold, was broken off, the sculpture was revealed as he had modeled it in wax except for projecting bronze rods and pouring channels which had to be cut down to the surface of the statue. This method, also used by the ancient Greeks and the Chinese, produces the finest quality of bronze casting; however, it is not always successful. Sometimes the bronze does not flow into all parts of the interior space, in which case the sculptor may have to repeat his work from the beginning. Giorgio Vasari (1511–1574) describes a method to avoid remodeling the original in such an eventuality by taking the precaution to prepare a piece mold of the statue before the enclosing envelope is put on.

A piece mold is a negative mold (as is the "envelope" discussed above) which is made in two or more sections so that when properly reassembled it will constitute a complete negative mold.

In making piece molds of plaster of paris from a clay or wax model, the division of the sections is obtained by inserting fences (thin strips of metal) into the model where such divisions are needed. If the model be of plaster or some other hard substance, area separators (thin strips of clay) are put on the model to form the boundaries of the sections. The separation of the sections in the metal casting technique, known as the sand-mold process, is achieved by applying thin layers of nonfusable material at the section boundaries.

When casting sculpture in metal it is desirable, if the work be of more than the smallest dimensions, that it be hollow. For this reason a core must be constructed to fit precisely within a piece mold so that there will be left between the core and the enveloping mold a space of just the thickness desired for the metal. Such cores are fixed in position with metal rods as in the lost-wax process.

Of all casting materials the most used by sculptors is plaster of paris (calcined gypsum, or sulphate of lime, or $Ca\,SO_4 \cdot \frac{1}{2}\,H_2O$). Except for its fragility it is an almost ideal casting substance. It is available everywhere cheaply. It is safe to handle, simple to use, and sets rapidly. Also it expands slightly on setting and thus tends to fill the mold completely to produce a clear cast. Usually when a work in clay has been modeled it is cast immediately into plaster, for the clay will not long maintain its shape under most conditions. Such a cast requires the making of a piece mold in plaster and then the use of the piece mold as a negative to cast a positive which will be a replica in plaster of the original clay. Specially prepared plasters are also used in making piece molds for the casting of nonferrous metals.

Of all the metals cast by the sculptor, bronze (an alloy composed chiefly of copper and tin) is the most extensively employed because of its great structural strength, resistance to atmospheric corrosion, ease of casting, and its fine, compact surface which permits a great variety of finishes in texture and color. Other metals cast as sculpture in the approximate order of their popularity for such use are: brass, copper, iron, lead, aluminum, pewter, silver, gold, and platinum. The last three are used mostly for very small works and jewelry. Other materials for which casting is an appropriate technique are: cement, and clay for terra cotta.

A variety of methods, materials, and tools are employed in finishing a work after casting. Besides removing the ridges left where sections of a piece mold join, and other protuberances such as the transverse bars used to hold cores in position, there are also apt to be holes, often caused by air bubbles, to fill up. Metal is filed, chiseled, or sometimes beaten, to bring out detail or modify the rough cast. Colors are changed or patinas added by the use of chemical fumes or baths. Sometimes metals are electroplated or inlaid with other metals.

Pointing is a term applied to the processes employed for copying three-dimensional models (or finished works) by the use of geometrical measurements and drilling. While sculpture of any material may be thus copied, models specially prepared for pointing are generally of plaster. The material on which the pointing is

executed may be any which is suitable for carving. Marble and limestone are probably the most used. The model may be the same size as the copy which will reproduce it, or it may be any reasonable fraction of its size, or even larger, for there are also devices to enlarge or diminish the scale.

The mechanics of pointing are best explained by describing a device used by Benvenuto Cellini. After the model was finished, Cellini chose a block of marble large enough to produce the statue in the size desired. Around both the model and the block were constructed identical frameworks like cubical boxes. A measurement then would be taken from the model by measuring so far down from the top of the framework, so far across from one of the sides, and so far in, almost to the surface of the model. The first two measurements would be repeated on the framework which enclosed the block of marble, then where the lines met, a hole would be drilled into the block until it reached the depth taken in the third measurement from the model. A great many measurements of such points, and the consequent drilling of them, would enable the sculptor to chip off the marble between the holes with the result that the block would assume roughly the form of the model. The more points taken, the closer the copy would approximate the model. The sculptor finished the work in the usual manner of carving marble by removing the final thin layer of marble.

While rough devices such as Cellini described, were used in Greek and Roman times and from the Renaissance through the 18th century for copying and enlarging, they were generally so used by the sculptor himself, who might in the finishing, leave the feeling of his own personal handling on the work. About the beginning of the 19th century, however, new pointing machines, infinitely more accurate, resulted in the development of pointing studios where models were reproduced by skilled workmen even down to the final finishing and polishing. Thus the sculptor tended merely to model in clay and cast in plaster. The actual carving was done in the pointing shops; just as the casting, if the model was to be translated into metal, was done in foundries.

Since the sculptor in the 19th century worked in clay, and thought in terms of modeling, many of the works of that period exhibit little appreciation for the beauty of the material into which the model was ultimately translated. Because of this, early in the 20th century there began a reaction against modeling with the result that many sculptors turned to direct carving, which they considered the only honest way for a sculptor to work. By direct carving they meant carving without the use of a preparatory model, although small, sketchy models were generally condoned. The aim of these reformers was primarily to make the materials of the sculptor expressive. Some artists would contemplate a particular stone or piece of wood until the shape, the color, and the grain of the piece suggested a form within which needed only to be freed by the sculptor's tools. Carving by the sculptor himself was thus reintroduced to the art. There is no doubt that this recognition of the expressiveness of the special qualities of a given material has helped to develop a new interest in the art of sculpture. The tenets of the direct carvers also influenced those who modeled for casting to the extent that they re-examined properties and possibilities of the materials used for casting. Some sculptors working in metals, have given up casting in favor of the direct handling of the metals by hammering, heating, and welding. So, too, the artists who continue to have their works pointed, have tended to study the nature of the materials pointed, and to do the finishing of their sculpture themselves when it is important.

Aesthetic Aims.—The aesthetic aims of sculpture are best treated in relationship to the practical factors which affect the individual works of art. These factors involve the use and significance of the work; size; if it be in relief or in the round; if it be made primarily for tactile or visual effect; and the material and technique.

By and large sculpture has been made for practical purposes: to produce magical effects as among primitive peoples; to make deities, idols for pagans to worship, or images for devotional purposes as for the Buddhists and various Christian sects; to embellish and give meaning to architecture; to perpetuate the soul as among the Egyptians; or to preserve the memory of persons and events. These significant purposes have generally been served by sculpture of considerable size, and there is no doubt that largeness promotes an effect of impressiveness in sculpture as it does in architecture. This is borne out by the observation that most sculpture which has been made merely to embellish or to delight is definitely under life-size or even of the statuette category. A notable exception to this rule is found in fountain sculpture from the 16th century on, where the architectural or arboreal setting often requires commensurate scale in the sculpture.

Sculpture, both large and small, may be in the round, made to stand free and be observed from all sides, or it may be in relief, that is to say, either attached to a background or made to be placed against a background. Most sculpture in the round proportionally reproduces the full roundness of the object represented, while sculpture in relief may vary from full roundness (high relief, *alto rilievo*), to a much flattened representation (low relief, bas-relief, *basso rilievo*). An intermediate degree of flatness is called mezzo relief (or *mezzo rilievo*); and an extremely flattened effect is spoken of as *rilievo schiacciato* (literally: crushed or squashed relief). Sculpture in relief is made to be seen from a limited angle of vision, while sculpture in the round may be designed to be viewed all the way round. To achieve success in sculpture in the round, the sculptor strives to produce a form which will have profiles and interrelations of masses that are interesting and effective from all points of view. The consideration of the point of viewing a work of sculpture sometimes affects the design and execution of a work; for example, when sculpture is destined for a greatly elevated position, as on a church façade, it may well be very simply designed and boldly executed, in order that the spectator shall be able to understand its message almost at a glance. Some work, too, which is in such a position, shows signs of adjustment in the proportions of the limbs of a figure to counteract the pronounced foreshortening when seen from below. Closely connected with these considerations are those which have to do with the lighting for which the work is made, and the distance at which it is normally viewed. For most sculpture soft, rather diffused light is agreeable, but some boldly under-

cut work as in the baroque style, gains force and dramatic effect when illuminated by a shaft of direct light, or spotlighted. Sculpture made for an open air setting must take into account the varied effects of light that will be encountered. This sculpture is apt to be broad in execution with little attention to subtle detail, and to exhibit very strong outlines, for under many lighting conditions such a work is seen chiefly in silhouette.

Sculpture, unlike painting, may be appreciated by touch as well as by seeing. Even if one does not actually touch it when contemplating a particular work of sculpture, the appreciation of the smoothness of surface and the modulation of one mass into another may be so strong that the mind receives the sensation of touching. This is commonly referred to as tactile quality, and oftentimes the kind of sculpture which produces a strong tactile expression is called plastic. Small works of sculpture, such as some of the Chinese jade carvings, invite one to take them in the hand. Naturally such a carving has pronounced tactile quality. Obviously different works of sculpture vary markedly in this tactile sense. Sculpture which appeals much more strongly to the visual sense is spoken of as pictorial. Such work is usually rough, might even be unpleasant to touch, and makes its effects largely by plays of light and shadow, often with extreme contrasts produced by deep holes or grooves.

The material chosen and the technique of fashioning adopted by the sculptor will vary according to the considerations discussed above except when the sculpture is made with no definite use in mind. In such a case a sculptor may, for example, permit an irregular boulder or unusual piece of wood to suggest a form, which then would be realized by direct carving, even letting the nature of the material alter the form while the work is in progress. Modelers in clay, when producing a work for exhibition or undetermined use, also enjoy a certain freedom from the dictates of significance, use, placing, and lighting. When the work, however, is commissioned for a particular use and place, then all of the other factors involved should be subservient. Generally speaking, this was true of sculpture until the advent of the 19th century when selling through the agency of exhibitions and dealers began to supersede the direct patron to artist relationship with rather unhappy results, for the sculptor, like other artists, benefits by exercising that discipline developed in solving specific problems of use and significance.

The criticism of sculpture is as difficult and complicated as that of any of its sister arts, but the recognition of quality in a work of sculpture is attainable by any intelligent person without too much study. As the noted scholar, Dr. Gombrich, wrote, "I do not think there are any wrong reasons for liking a statue. . . ." That authoritative statement should give courage to the beginner. To put it in brief: what makes a work of art good is when every part and every factor is working together to enhance the effect of the whole. To judge a work of art one should contemplate it until its message is clear; then, and only then, analyze it to determine if all its parts and its handling are right for achieving that message. Do not condemn a work for being what it is not; do not ask a Romanesque figure to have Greek proportions, nor expect an abstract work by Constantin Brancusi to reproduce nature as much as a statue by Auguste Rodin.

Sculpture Related to Architecture.—Architectural sculpture may serve to illustrate the application of some of the factors discussed above to particular problems. In Egypt, sculpture on the exteriors of temples was simplified to deeply incised outlines with only slight modeling of the figures within (sunken relief) in order that the viewer readily might read the meaning in the prevailing, intense light. On the interior walls of temples and tombs the use of low relief prevailed. Where the light was dim this relief was made more visible by painting. In Mesopotamia the outstanding use of architectural sculpture was to embellish the lower portions of the walls of open courtyards with bands of low relief recounting deeds of the kings. Because these would be seen close up and were in shadow much of the time the very flat relief needed only slightly raised outlines with a system of bumps and grooves reserved to emphasize important areas, such as heads and arms. The later Babylonians faced the exterior walls of city gates and ziggurats (pyramidal towers of worship) with colored glazed tiles which had animals formed in relief on them. Since the animals were done in colors contrasting to the plain wall areas, they told readily even in brilliant light.

The Greeks, too, used color on their sculpture: marble statues had tinted hair and touches of color in the eyes, on the lips, and in decorative patterns of the draperies; bronze figures often had inlays of other colored metals or enamel; while those made of inferior materials, such as limestone, terra cotta, and wood, were often entirely painted. From traces of pigment still extant, it is clear that color was extensively employed for architectural sculpture. The most important use of sculpture on Greek temples of the developed period was in the pediments (the wide, rather low gables) which were filled with groups of figures carved in the round, but which because of their enclosed position told as reliefs. The backgrounds for these groups were generally painted a deep blue against which the light marble statues stood out in golden splendor. The clarity of the individual figures was heightened by arranging them so that one did not much overlap another. They were like actors carefully posed on a long stage only two feet deep. This was especially true in the earlier works such as the temple at Aegina and the Temple of Zeus at Olympia. The famous pediments of the Parthenon, done under Phidias, had the figures arranged with more overlapping, with the effect of greater backward and forward movement, and consequently with less clarity of outline. To cause his groups to be effective at the 50 or more feet from which they would be seen, Phidias introduced pronounced modeling and undercutting so that a play of rich shadows would bring out the forms. Greek temples also used sculpture in the friezes (horizontal bands above the columns) which also were high above the ground on the larger temples. In the Doric order this sculpture was in square plaques (metopes); in the Ionic it was in a continuous band. Such work was executed in low or mezzo relief. In general one feels that Greek sculpture maintains its identity as sculpture though it blends harmoniously with the architecture and embellishes and adds to its meaning. Most free-standing Greek sculpture, on the other hand, seems to have a strong affinity for architecture. This is illustrated by the fact that when displayed in museums it is most

effective when set against walls or even placed in niches.

The Romans used sculpture architecturally much the same as the Greeks. The Romans did, however, employ relief, both of figures and of ornament, for what might be called a textural, decorative effect on walls, vaults, and other architectural surfaces. When such a textural effect develops, sculpture tends to become ancillary or secondary to the architecture instead of maintaining its status as an equal and relatively independent art.

Sculpture on medieval buildings was distinctly subservient to the architecture. Especially was this true up to the Gothic period. On the façade of the Church of St. Trophime at Arles the sculpture was so intimately woven into the architectural elements that the separation of the two arts is here unthinkable. Figures seem to grow out of the walls, to be part of one organic creation. Figures were often distorted to fit architectural areas, or, as on the west façade of the Cathedral of Chartres, they were elongated to accord with the architectural character of the columns to which they were attached.

The Gothic period of the 13th and 14th centuries witnessed a gradual and partial emancipation of sculpture from architecture. Then, as seen on the great cathedrals of Amiens, Reims, and Bourges, sculpture in low relief and sculpture that was placed high remained, as in the Romanesque period, a part of the architecture giving textural richness and added emphasis to architectural form. But statues in niches or scenes in high relief which were near eye level began to be more independent of their architectural setting, though still heeding its demands.

The great sculptors of the Early Renaissance, like Donatello in his statues for niches on the campanile of Santa Maria del Fiore and Or San Michele, gave their statues so much character and vitality that one hardly thinks of the architectural functions. The latter do exist, however, even if they seem to lie chiefly in the realm where the architecture is ancillary to the extent of providing a frame and setting for the sculpture. The independence of the sculpture is often more marked by being different in color and material from the architecture.

During the High Renaissance of the early 16th century the relationship of sculpture to architecture was similar to that of Greek classical times: the two arts were working together in a fine balance, neither striving to dominate the other. The best illustrations of this, though a bit late for the period, would be the Loggetta and the library of St. Mark's Church in Venice by Jacopo Sansovino and assistants. In the continuance of Renaissance architecture into the 17th and 18th centuries there was little change in this relationship; but on the whole sculpture tended to become more subservient in the later periods when it was often used to enliven, sometimes almost animate, certain features of the architecture, especially where the building meets the line of the sky. This sculpture, while bold in its outlines and undercuttings, was generally coarse in execution (because it was not to be seen close by), and of little merit when taken from its original setting.

Sculptors of today can learn something from the great architectural sculpture of the past, but they must remember that a new style of architecture requires a new relationship of sculpture to architecture. From the past both sculptor and architect can learn effects of placement and lighting. They can learn the value of contrasts of color and material, and the telling power of light and shade and silhouette. Also they should be able to discern in what ways sculpture will enhance and give aesthetic accent to architecture.

HISTORY

The history of sculpture goes back to the paleolithic period in western Europe, a time when man was also making the earliest known paintings. Typical works are small statuettes of women, and reliefs of animals of the chase, reindeer and bison. Some though in soft clay have been miraculously preserved, many are engravings on bones or antlers, and some are carved in very soft stone. As might be expected, since these were executed before the use of metal was known they are simple in technique; many, however, are remarkable either for their organization of sculptural masses, or for their seizure of essential characteristics to achieve lifelike forms. It is believed that this early sculpture was eminently practical in a magical sense; for example, that the making or possession of a representation of a bison would ensure the hunter of success in hunting that animal.

Egypt.—Egyptian sculpture we know was highly endowed with magical properties. For the ancient Egyptian the representation of an object stood for the object itself. This was particularly important for the Egyptian credence in a life after death. The Egyptians believed that an aspect of the soul, called the *ka,* was a counterpart of the body, that it was born with the body, continued through life with the body, that it looked like the body, though invisible, and that at death they went together into the next world. It was essential to the everlasting life in the hereafter that the likeness of the body be preserved. This was done first by mummifying the corpse, and later also by making more permanent replicas of the body in sculpture. Thus the Egyptians were the first to develop the art of portraiture. The depiction of food, animals, servants, and acts of service, largely in relief or painting, also served the magical duty of providing for the wants of the *ka.* It was to provide for the life in the future that the tombs of the kings and nobles were so completely furnished and adorned with portraits in the round and pictures on the walls.

The earliest known large portrait statue is that of King Zoser, of the 3d dynasty (c.2700 B.C.), whose tomb was the first pyramid, the Step Pyramid at Saqqara. By this time Egyptian civilization and its art seem to have been realized in the essential form that it was to continue for more than 2,000 years. Some of the finest portraits were produced not long after Zoser in the period known as the Old Kingdom (2700–2200 B.C.). From then came the great diorite *Khafre* in the Egyptian Museum at Cairo; the double portrait of Menkure (Menkaure) and his queen in the Boston Museum of Fine Arts, executed in a dense slate; the seated *Scribe* in the Louvre of painted limestone; and the wooden statue, known as the *Sheikh-el-Beled,* also in the Egyptian Museum at Cairo. Egyptian statues, such as these, represent nearly always figures either standing or seated, and observe what is called the "law of frontality" (a plumb line dropped from the middle of the forehead would

divide the figure into two virtually equal parts). There is no bending to right or to left, and the head always faces straight forward.

In the Middle Kingdom (about 2050–1800 B.C.) portraiture continued to use the same poses and conventions. Royal portraits of this period, like the head of King Amenemhat III in the Ny Carlsberg Glyptothek, Copenhagen, usually seem less idealized than the earlier portraits with more detail in the features utilized to bring out not only the personality but even the thought of the king.

During the period known as the Empire or New Kingdom (about 1465–1090 B.C.[1]) the old forms, with some notable exceptions, continue. The lifesize figure in basalt of Thutmose (Thothmes) III in the Egyptian Museum at Cairo is one of the finest examples of the conservative tradition. Colossal portraits in the traditional mode and broadly executed are also characteristic of the Empire. Such are the four huge statues, more than 65 feet high, cut out of the living rock in front of a temple at Abu Simbel in Nubia. Some of the statues and statuettes of this period, however, are more lifelike than usual in Egyptian art, and tend to deviate from the old conventions. Especially is this true of the portraits of Ikhnaton, the rebel king, and his wife, Nefertiti (Nofretete), which attain a high degree of individuality and naturalism.

Egyptian sculpture in relief is usually very low in projection, sometimes hardly more than incision, and is closely related to Egyptian painting in its conventions, which derive largely from the desire to represent things, or parts of things, in their most characteristic attitudes. The head is shown in profile, but the eye is full face as are the shoulders and the chest, while from the waist down the profile is again employed. Kings are represented much larger than servants. Depth is indicated by placing distant objects above those which are nearer. These characteristics were established very early, as shown in the Palette of King Narmer in the Egyptian Museum at Cairo from about 3000 B.C. By and large, sculpture in relief in the early period was used on portable works; in the Old Kingdom, primarily for the walls of the tomb chambers; while in the Middle Kingdom, the Empire, and later, besides these uses, relief for the embellishment of temples was common. For this purpose the Egyptians developed what is called "sunken relief," where the outlines of the figures are deeply carved into the surface of the stone and the figures within are only lightly modeled. Nearly all relief was painted.

Mesopotamia.—Mesopotamian sculpture, like the civilization of that region, paralleled the Egyptian chronologically (c.3000–539 B.C.). Three important factors influenced a development different from that of Egypt: first, stone had to be imported at great expense; secondly, the people had no cult of the dead which fostered the art; and thirdly, since the land was not protected by natural barriers, invasions with consequent changes in religious and cultural outlooks prevented the continuation of inflexible traditions. From early times small statues of priests or priest-kings like the diorite *Gudea* in the Louvre from about 2450 B.C., and reliefs picturing important events, are the most notable forms. Sculpture in the later period under the Assyrians (c.1275–607 B.C.) was largely employed for the decoration of the walls in important areas of the royal palaces. Reliefs from the palaces of Ashurnasirpal (r. 884–859 B.C.) and Ashurbanipal (r. 669–626) depict the lives of those kings. Also characteristic are the colossal, man-headed and winged bulls and lions which flanked the chief entrances to the palaces. The British Museum in London is the greatest repository of Assyrian sculpture but splendid examples may also be seen in the Metropolitan Museum of Art in New York and at the Oriental Institute in Chicago.

The general traditions of Mesopotamian sculpture, which obeyed conventions similar to the Egyptian, continued in the Achaemenian Persian period (539–331 B.C.) with some Greek influence apparent in the later work. The greatest site was Persepolis.

Greece.—In Greek lands the earliest sculpture, of great interest to 20th century artists because of its abstract form and simple, beautiful handling of marble, is a group of violin-shaped idols from the Cyclades (about 3000 B.C.) now in the National Archaeological Museum at Athens. Then followed the brilliant Aegean civilization (c.3000–1000 B.C.) with its chief center the island of Crete, which produced little sculpture of large size, but many statuettes in terra cotta and ivory, and very remarkable small reliefs in various materials. Of large works the Lion Gate at Mycenae (about 1400 B.C.) is the most eminent, and of the smaller, outstanding are the gold *repoussé* cups from Vaphio (c.1500 B.C.) with bulls in relief.

Greek sculpture, properly speaking, began a few centuries later, after the Greek-speaking invaders of the Aegean area had settled down to create a culture of their own. Sculpture from the Geometric period (about 900–700 B.C.) consists mostly of bronze statuettes of warriors and horses. These figures are of elongated proportions with a tendency to emphasize triangular masses. Large cult statues were probably made of wood, as we are told they were in the succeeding period.

After the Geometric period the general course of Greek sculpture was toward ever-increasing naturalism. This tendency was fostered by the nature of the Greek religion whose gods and heroes were conceived in human form, only more perfect and more powerful than ordinary men. Also the association between the worship of the gods and the great, periodic athletic games, such as those at Olympia, turned the minds of the people toward the appreciation of physical beauty and thus spurred on the artist's search for ways to depict that beauty more and more naturally. The ensuing periods of Greek art are differentiated primarily by their changing factors of naturalism.

The Archaic period (650–480 B.C.) is usually divided about 550 B.C. into early and late phases. Examples of Greek archaic sculpture are abundant and of many materials, except wood because that has perished, both in relief and in the round. For statues in the round the "law of frontality" held as in Egypt and Mesopotamia. For figures in relief, which includes pedimental sculpture, the desire to represent things in their most characteristic attitudes was particularly strong during the early phase of the archaic when a single figure was done part in profile, part in full face. It is reasonable to assume that the older traditions of Mesopotamia and Egypt influenced Greek sculpture of this time.

The types used in free-standing sculpture were

[1] Some chronologies date the Empire 1580–1085 B.C.

chiefly the standing male nude, or "Apollo" type, which apparently was employed to represent both gods and athletes with no variation which we are able to perceive in most cases; and draped female figures either seated or standing. The increase in naturalism from the early to the later archaic was great and was accompanied by technical advances in the working of marble and the casting of bronze. In fact the casting of large statues in bronze toward the end of the period was a proper accompaniment to the growing naturalism, for such castings were based on modeling, a technique of fashioning sculpture which invites a naturalistic approach. From this time on bronze was the most used material in Greek sculpture other than that employed for architectural decoration; and the practice of modeling affected the design of the work in stone as can be seen in the late archaic pedimental groups from Aegina, now in the Glyptothek at Munich.

The Transitional period (480–450 B.C.) produced one very famous master, Myron, whose bronze originals, such as the *Discobolus* and the *Boy Extracting a Thorn from his Foot* are known to us only through later copies. However, one can get a good idea of the restrained and dignified naturalism of the period in the bronze *Charioteer of Delphi*, museum at Delphi, and the *Zeus* in the museum at Athens, both by unknown artists. The great monument of architectural sculpture of this style was the Temple of Zeus at Olympia. Well-preserved pieces of these marbles are in the museum at Olympia.

The Golden Age, the great period of Greek sculpture, is customarily divided into 5th century (450–400 B.C.) and 4th century (400–300 B.C.). Undoubtedly the creations of two of the world's greatest masters, Polyclitus of Argos and Phidias of Athens, determined to a great extent the character of sculpture during the Golden Age. The art of this period is so impressive in its quiet dignity, so reserved in its expression of power, and so measured in its fine naturalism, that we have long called its products classic (which means, literally, first-class). Though many admired originals exist from the 5th century, ironically there is no work which we can say was done by the hand of either Phidias or Polyclitus. The nature of the latter's style may be fairly well observed in the *Doryphorus* or *Spear Bearer*, a marble copy of a lost bronze statue by Polyclitus. It is a stocky athletic figure with the anatomical details broadly but strongly rendered. The head is more natural than in earlier Greek work but not so natural that it draws attention from the harmonious, powerful body. Polyclitus established a norm for the depiction of the male nude not only for Greek sculpture but for later Western civilization, so much so that subconsciously even people who have never heard of Polyclitus tend to measure the deviation of other works which may be much more realistic, or stylized, or distorted, against that norm.

The accomplishment of Phidias in establishing classic ideals was even greater, if we can judge correctly on the basis of copies and the extant fragments of the sculpture from the Parthenon, which was done under his direction. Phidias created gods, or, at least, established our visual concepts for them. The echo of his serene, powerful types for Zeus and Athena has continued through the ages. Also it would seem that we owe to Phidias the development of a whole new order of poses which are at once serene and graceful as well as expressing a latent power for action. This is seen in the fragments from the pediments of the Parthenon, which also reveal a new music in the rendition of draperies, which are naturalistic and expressive of the bodies to which they cling.

In the 4th century the serene nobility of concept continued but began to be tempered by more human emotions. Naturalism developed to show figures in more active poses, to render the soft textures of skin and hair, and to depict emotions. It is not surprising then that during this period true portraiture first appeared in Greek sculpture. Three great sculptors dominated the age. Scopas of Paros, whose style is known through ancient descriptions, copies, and some heads found at Tegea, where he was the architect of the Temple of Athena Alea, made use of his greater anatomical knowledge to render figures in poses expressing great emotional tension. His heads, too, depict violence of feeling in their wide-open eyes, distended nostrils and parted lips. Praxiteles, the most famous sculptor of the period, is known for his exceedingly graceful, languorous renditions of Aphrodite (Venus) and the younger male gods. Characteristic are his relaxed, "S-curve" poses, the dreamy, contemplative expression of his heads, and his caressingly soft treatment of the texture of skin. His famous nude Aphrodite of Cnidus, known through a copy in the Vatican, serves to illustrate that Praxiteles set the standard for future sculpture of this subject. His Hermes, discovered in 1877 in the excavation of a ruined temple at Olympia, where Pausanias said he had seen it, is considered to be the only sure work we have from the hand of any of the most famous Greek sculptors. Seemingly, Praxiteles was the only one among these greatest of the Greek sculptors who used marble in preference to bronze for his works. The third, and decidedly youngest sculptor of the period, was Lysippus, who is said to have made many portraits of Alexander the Great, and to have produced 1,500 works, all in bronze. Ancient descriptions of his style accord with the *Apoxyomenos* or the *Scraper*, a marble statue in the Vatican, believed to be a faithful copy of a lost, bronze original. The freedom of pose, the detailed handling of anatomy, and the almost portrait-quality of the head will illustrate the fairly high degree of realism attained in the latter part of the 4th century. His brother, Lysistratus, is said to have been the first Greek sculptor to take a cast from the face of his model, which, of course, is an indication of the developing realism which was to mark the following period. The outstanding examples of architectural sculpture from this time are the marble statues and reliefs, mostly in the British Museum, from the Mausoleum at Halicarnassus.

The Hellenistic period which dates from the death of Alexander in 323 B.C. to the Roman conquest of Greece in 146 B.C., witnessed the spread of Greek culture into Egypt, the Mesopotamian Valley, and east to the Ganges. Established native traditions in some of these regions, in Egypt and Gandhara in northwestern India for example, modified the Greek quality of the sculpture produced there, but on the whole, sculpture of the Hellenistic civilization continued to develop much the same as it might have, had its area of production been confined to Grecian territory. The chief tendencies were toward greater realism both in subject and treatment, and the search for novel and striking effects. Many works, however, preserved the dignity and restraint of the Golden Age. Some notable works of classic spirit are: the *Aphrodite of Melos* (*Venus de Milo*) in the Louvre, the *Aphrodite of Cnidus* in Rome, and the *Victory of Samothrace* also in the Louvre. The elegant *Apollo Belvedere*

in the Vatican, which influenced so much the art of the Renaissance and later periods, is very likely a Roman copy of a bronze original from the late 4th century. The new realism is seen in the pathetic bronze *Boxer* in the Naples Museum, in the bronze *Hellenistic Ruler* in Rome (a full-length portrait in the nude), and in many genre (subjects from everyday life) works, such as the *Old Market Woman* in the Metropolitan Museum and the *Boy with a Goose* in the Capitoline Museum, Rome. Also realistic is the *Dying Gaul,* Capitoline Museum, a copy of a work from the school of Pergamum, a city-state in Asia Minor. A later work from Pergamum, the *Altar of Zeus,* combined the heroic proportions of Phidias with an intensification of the emotional qualities of Scopas. The *Laocoön* group also is in much the same spirit.

Etruscan.—Etruscan sculpture early developed a remarkable tradition in the Italian peninsula. Early Etruscan bronze devotional figurines, often extremely attenuated, are admired for their expressiveness and sympathetic use of the material. From the 6th century on Greek influence is manifest. Large painted, terra cotta figures of amazing technical skill were used for temple pediments, and on sarcophagi to represent the deceased. The Etruscans developed lifelike portraiture earlier than the Greeks, primarily for funeral purposes.

Roman.—Roman sculpture evolved from Etruscan and continued, in many respects, the Hellenistic traditions. Indeed, it would seem that great numbers of the sculptors were of Greek origin. Also Rome imported works of sculpture from Athens and other centers of Greek art. The term, Roman, however, applies not only to the city of Rome, but also to the huge empire which that city built up, thus sculpture from Athens or Spain is called Roman if done during the period of Roman dominance.

For the making of statues of gods and heroes the Hellenistic tradition continued, though weakened in vigor and originality by the Roman collectors' preference for older works, or even copies of them, to any new work showing great originality. In the field of sculpture in relief, for which the demand was great, the situation was not so static, though one cannot discern a clear line of development. Under Augustus (27 B.C–14 A.D.) the sculptors of the *Altar of Peace* (*Ara Pacis Augustae*) were rather academic in following Hellenistic and earlier Greek models for reliefs of a sacrificial procession and allegorical figures, but manifested true originality in their fine carvings of garlands of fruit and flowers. Two reliefs on the Arch of Titus (*Arcus Titi,* dedicated in 81 A.D.), achieve a new effect of depth and atmosphere by placing figures in different planes and by using a variety of heights of relief. The two great commemorative columns of Trajan and Marcus Aurelius from the 2d century A.D. in continuous bands spirally wound around the columns, narrate episodes in the military campaigns of the two emperors. Late works, like those on the Arch of Constantine (Arcus Constantini, dedicated in 315 A.D.), often frankly renounce classic naturalism, and revert to early Mesopotamian conventions of squat proportions for the human figure and simple superposition to indicate space. By classical standards these works would be judged bad; they have, however, a certain rough vigor and fitness to use and material all their own.

Portraiture was ever important to the Romans, who employed portraits in their cult of ancestor worship. Nearly all Roman portraits, one feels, were good likenesses. Many are masterpieces. To single out a few: the Junius Secundus from Pompeii, the Augustinian princes in the Prado, several of the benign Emperor Trajan, and all of the wicked Emperor Caracalla.

Early Christian Sculpture.—Christians, as early as the 2d century, adopted the regional pagan styles, modifying pagan elements to their own use. They seldom made statues in the round but employed relief extensively on marble sarcophagi. Of these many are known, and the research of scholars has shown that the great variation in type and style among them was due to the different provincial centers of production, as well as to period. Allegory and symbolism were much used: as the Good Shepherd standing for Christ, or vineyard scenes which symbolize the sacrificial wine. Scenes from the Old and New Testaments were frequent and were important because they helped to fix the representation of these subjects in the classic tradition, however diluted that tradition had become. These sarcophagi date largely from the 3d through the 5th centuries.

By the beginning of the 6th century the invasion of Teutonic tribes had so disrupted the way of life in western Europe that one must turn to the Eastern Roman civilization, with its center at Constantinople (or Byzantium), to follow the development of sculpture. There the production was intermittent because of a widespread tendency to regard "the graven image" as a sign of paganism. The sculpture of the Byzantines, however, was important, for it kept alive the plastic inheritance of antiquity for medieval Christianity. Typical are the small devotional plaques of ivory carved with religious subjects. Most of these are from the 10th and 11th centuries, though earlier examples exist.

In western Europe the history of sculpture resumed importantly about the year 1000 A.D., when the bronze doors on the Cathedral of Hildesheim, Germany, were made for Bishop Bernward. The Biblical scenes here have a feeling of life and intensity which augurs the great medieval art to follow.

Romanesque.—Romanesque sculpture exhibits the renewed vitality of Western culture in the 11th and 12th centuries. A factor, highly favorable to its development, was that sculpture at this time was eminently useful. Nearly all Romanesque sculpture was for the embellishment of churches and sacred objects. It follows that most of it is in relief, be it in the stone of which the churches were built, or be it in the gold or bronze or wood of the object it adorned and gave meaning to. As far as naturalism and limitation of technique are concerned, there is a certain analogy between Romanesque and Greek archaic sculpture, but the differences in subject, purpose, and emotional content are most marked. The Romanesque sculptor distorted the human figure and made unnatural patterns in his draperies, not so much for expression, but to coerce his designs into the shapes of capitals, or columns, or to run along the bend of a bishop's crozier. Superb examples of the architectural sculpture are to be seen in many parts of France; notable are the portals of Saint Pierre at Moissac, the church at Souillac, and the façade of St. Trophime at Arles. A variation of the French work may be seen in a portal at Santiago de Compostela in Spain. In Italy, the Baptistery at Parma is outstanding. Bronze work of the period is well represented in a series of Italian doors at Trani, Monreale, Ravello, Pisa, and Benevento. Many of the Italian works bear the signature of the artist.

Gothic.—Gothic sculpture was the product of an age still intensely religious but which manifested a new, broader outlook. Signs of this are perceptible in religious practices and reflected in art. The more austere, older monastic orders were losing favor while the new orders of friars, the Franciscans and Dominicans, gained enthusiastic following. The Dominicans, a preaching order, exhorted people to choose the good way of life, and stamped out heresy. The Franciscans by their humility and simple faith showed people how to live in the way of Christ. Both orders appealed directly to the individual man. Religion was humanized. Accompanying these changes came the development of a new mode of everyday life. Trade from region to region, from one nation to another, began to replace an almost completely local economy. Banking developed. People traveled more, and villages grew into towns. A middle class of merchants and artisans was born.

The reflection in art of these changes was profound. In Romanesque times the greatest buildings were monastic, built for monks with funds from the nobility; the glory of the Gothic period lay in its great cathedrals, built in towns and paid for largely by burghers. Sculpture became more natural to keep pace with the increased importance of the individual man, and to portray the new intimacy and tenderness of religion. This is shown in many ways. Sculpture used architecturally became more independent of the restrictions of its architectural placement, and began to create space in which figures could move. Portraiture gradually developed so that by the end of the period fairly convincing likenesses were made. Innovations in facial expression and gesture met the new demands for emotional characterization. In a way, even the subjects became more natural. The dominating Romanesque theme of Christ the Ruler gave way to the representation of the Madonna and Child, which offered the artist much greater opportunity to express the very human relationship of mother and child.

The dating of the Gothic period is complicated: the 13th and 14th centuries comprise the heart of the period, but because of the continuation of the Gothic style in architecture into the 15th and even 16th centuries, the terminal date is ambiguous, and it varies in different regions.

France was the cradle of Gothic art and it is to that country that one must turn to see the finest of Gothic work. There most of the medieval cathedrals have splendid sculpture. One might single out for examples of the early 13th century the central portal of the west façade of Amiens with its rows of lifesize patriarchs and apostles flanking the doors, between which is the gracious figure of Christ Blessing (*le Beau-Dieu*). Above is a large relief of the Last Judgment enframed in a series of pointed arches bearing over 100 figures. The portal of the south transept at Amiens illustrates the greater naturalism of the later 13th century. The central figure is the Madonna and Child (known as *la Vierge dorée* because the limestone statue was originally covered with gold leaf). Other particularly fine works of the 13th century may be seen on the south porch at Chartres, the west façade of Reims, and the portal of the south transept at Strasbourg. The 14th century produced portraits which were increasingly lifelike, but otherwise the greater naturalism has a tendency to waste itself on details of costume and rather over-elegant poses and expressions. The *Virgin of Paris* in Nôtre Dame is a typical illustration.

Not without French influence, but with more powerful individualization, are the finest of German works of the 13th century, such as the statues of the 12 benefactors of the Cathedral of Naumburg. English sculpture, although likewise strongly under French influence, lacked the vitality and distinction of the continental work. Something of the same might be said of Spanish Gothic.

Only in Italy during this period was there a strong native style that long resisted French influence. There on the Arch of Frederick II at Capua (1234) antique models were so ably employed that the heads and busts seem almost Roman. Out of this south Italian school came Nicola Pisano (1220–1284) whose hexagonal pulpit (1260) in the Baptistery of Pisa combined the imitation of the antique with a keen rendition of actual life. His son, Giovanni Pisano (1245–1314), probably under French influence, produced pulpits and Madonnas of high emotional content and increased realism. The great master of the next generation was Andrea Pisano (1270?–1348) a Florentine, not related to the above. His master works were the parcel gilt bronze doors now in the south portal of the Baptistery of Florence. Andrea's work is closely related to that of the painter, Giotto (1276?–?1337), in its combination of telling naturalism and measured restraint.

The Renaissance.—Renaissance sculpture in most respects is simply a continuation of the Gothic with certain tendencies of the Gothic accentuated. On the whole, one might say the same of the contemporary civilization. As trade, manufactures and cities flourished, so likewise did the independence of the individual increase. The burgher had to exercise his personal judgment and taste in the wares he made or bought, so, too, did he in the art he ordered. Out of this the individuality of the artist emerged, for the patron would seek out that artist whose style and expression pleased him most. The growth of trade encouraged inventions and discoveries. The same spirit was manifest in art: the laws of perspective were worked out, bodies were dissected to learn the secrets of anatomy, and treatises on techniques and the nature of art appeared. By 1500 most of the means for attaining naturalism had been explored and were available to an artist like Leonardo da Vinci. With the emergence of the individual, men developed the right to entertain their own opinions on beliefs hitherto accepted dogmatically. One manifestation of skepticism affected religion and produced reformations, both heretical and within the Catholic Church. Another manifestation, bolstered by a much increased knowledge of the writings and art of the ancient Greeks and Romans, influenced the subject matter and style of art. It is in this classical influence that one finds the most distinguishing characteristic of art of this time. Indeed the term Renaissance, literally "rebirth," means the rebirth of antique learning and forms.

The Renaissance may be taken as comprising the 15th and 16th centuries. In Italy the 15th century is known as the Early Renaissance; the first generation of the 16th (roughly 1500–1530), the High Renaissance; and the remainder of the 16th, the Late Renaissance. In the rest of Europe the new classicism did not prevail until the 16th century. The factor of classicism in Renaissance art is Italian, but the emphasis on individuality and the development of naturalism, which were equally important factors, were common to all of western Europe.

It may be affirmed that the first true Renaissance

art was in the field of sculpture. In 1401 the Merchant's Guild of Florence held a competition to choose a sculptor to make another set of bronze doors for the Baptistery of Florence, to match those of Andrea Pisano. The trial panels (preserved in the National Museum, Florence), of Lorenzo Ghiberti (1378–1455) and Filippo Brunelleschi (1377?–1446), representing the Sacrifice of Isaac, both reveal the major aspects of the new style: interest in the anatomy of the nude human body, a rich play of emotional expressions, a variety of poses in orderly but complicated compositions, and direct influence from antique sculpture. Ghiberti went on to do the portals (1403–1424) and still another set, the so-called "Gates of Paradise" (1425–1452).

The most versatile and most powerful sculptor of the first half of the 15th century was Donatello (1386?–1466) a Florentine, who exploited all techniques of sculpture in producing reliefs and statues which run the gamut of emotional expression from the delicate meekness of the *Annunciation* in Santa Croce and calm assurance of his great equestrian bronze statue of Erasmo da Narni, called Gattamelata, in Padua, to the profound pathos of the starkly realistic *Zuccone* on the Campanile and the wooden *Magdalen* in the Baptistery. A somewhat younger contemporary, Luca della Robbia (1400?–1482) fashioned his *Singing Gallery* for the Cathedral of Florence with delicate realism. Luca also introduced the new technique of colored, glazed terra cotta in which he did many beautiful works.

In the second half of the 15th century, Florence produced much sculpture of outstanding quality. Notable are the exquisitely sensitive marble reliefs of Desiderio da Settignano (1428–1464). Antonio Rossellino (1427?–1479) and Benedetto da Maiano (1442–1497) followed the same path. The outstanding sculptors of the time, however, were the realists, Antonio Pollaiuolo (1429–1498) and Andrea del Verrocchio (1435–1488). Pollaiuolo is credited with being the first modern artist to dissect the human body. His remarkable ability to use anatomy as an expressive vehicle is seen in the bronze statuette group, *Hercules and Antaeus* in the National Museum at Florence. Verrocchio, the master of Leonardo da Vinci, followed Pollaiuolo in mastering anatomy and extended its application in the field of facial expression as illustrated in his psychologically charged bronze group of *Christ and St. Thomas*. A supreme example of his dynamic realism is the bronze equestrian statue of General Bartolommeo Colleoni in Venice. The greatest sculptural achievement of the Early Renaissance was in Florence, but other regions of Italy also produced great masters: Jacopo della Quercia (1378?–1438) of Siena was a worthy rival of Ghiberti and Donatello; the Dalmatian, Francesco da Laurana (c.1420–c.1503), produced busts of esoteric beauty; the Venetian, Antonio Rizzo (1430?–?1498), combined Florentine features with German expressiveness; and the Emilian, Guido Mazzoni (1450–1518), produced dramatically realistic works in painted terra cotta.

Fifteenth century sculpture in northern Europe and Spain, like the Italian, developed realism in various ways. This is seen clearly in the work of Claus Sluter (d. 1406), a Dutch-Burgundian, at the very beginning of the century. His limestone *Well of Moses* (1395–1403) at Champnol near Dijon, represents four prophets so realistic in type and pose that they seem to have just stepped out of one of the contemporary mystery plays. The same feeling of actuality was carried by a Dutchman, Nicolaus Gerhaert of Leyden (c.1430–1473) into southern Germany. German sculptors continued the trend of dramatic grouping and intensified the emotional content of their figures, both in wood and stone. Significant artists were Veit Stoss (1440?–1533) with his *Shrine to the Virgin* (1477–1487) for the Marienkirche in Cracow, Adam Krafft (Kraft, 1450/55–1508/9) with many works in Nürnberg, and Tilman Riemenschneider (1460?–1531) whose dreamy, melancholy work is best seen in Würzburg. Netherlandish and German artists carried their traditions to Spain where there was an almost insatiable demand for ecclesiastical sculpture. French sculpture followed in the course laid down by Claus Sluter at Dijon with modifications tending toward quiet restraint. This is illustrated in a series of depictions of the Holy Sepulcher, of which a typical example is in the Hospital at Tonnerre (1454). Toward the end of the century Italian influence, especially in the use of classical ornament, appeared in the work of Michel Colombe (1430?–1512).

The High Renaissance in Italy was characterized by a markedly increased influence of the antique not only in types and details such as headdress and draperies, but even in the measured naturalism of classicism. This is illustrated in the sculpture of Andrea Sansovino (1460–1529) whose tombs of the cardinals Girolamo Basso della Rovere and Ascanio Sforza in Santa Maria del Popolo, Rome, imitating the form of the Roman triumphal arch, have figures of classic quiet and beauty. His pupil, Jacopo Tatti, also called Sansovino (1486–1570), continued the same trend in Venice. But the outstanding sculptor of the period, and indeed of the entire Renaissance, Michelangelo Buonarroti (1475–1564), did work too powerful and too varied in its expressiveness to be categorized so simply. His early works such as the *Bacchus* (about 1500) and *David* (begun 1501), both in Florence, show him conquering the problems of anatomy. His use of the nude in these statues is chiefly for the expression of realism. His *Moses* (San Pietro in Vincoli, Rome) and the *Bound* and *Dying Slaves* (Louvre, Paris), the only important finished parts of his great tomb for Pope Julius II (begun 1505), exhibit his mature mastery of anatomy to express diverse human emotions. The *Moses* with superhuman strength springs forward in wrathful indignation. The *Dying Slave* resigns his earthly life for the sweet sleep of death. Both works are pure poetry with every element in each, working to produce the desired effects in greatest intensity. Michelangelo's later Medici tombs in San Lorenzo, Florence (1520–1534), reveal other, equally powerful, variations of his mastery of the human body. The poses are forced and proportions are exaggerated but one would not call the figures unnatural. In his latest works (after 1550), however, Michelangelo severely distorted the human body to express his soul's anguish as in the *Pietà Palestrina* (Academy, Florence), a group of the Virgin and Mary Magdalen supporting the impossibly heavy body of the dead Christ.

Sculpture of the Late Renaissance in Italy followed two paths: one which exaggerated Michelangelo's use of pronounced muscles, twisting poses and elongated figures; and the other which more clearly was inspired directly by the antique. The Michelangelesque manner was used mostly for large works: architectural sculpture, fountains, public monuments and tombs. The classicizing tendency was pronounced in garden sculpture and bronze statuettes. Important sculptors of the period

were Il Tribolo (Niccolò Pericoli 1500–1550), Benvenuto Cellini, famous as a goldsmith (1500–1571), Bartolommeo Ammanati (1511–1592), the Italianized Fleming, Giovanni da Bologna (Jean Boulogne, known as Giambologna, 1529?–1608), and the Venetian, Alessandro Vittoria (1524–1608).

Italian influence in northern Europe and Spain was spread by traveling Italian sculptors, by foreign artists who completed their studies in Italy, and by a lively trade in exporting Italian sculpture especially around the western Mediterranean.

For Spain, the Florentine, Domenico Fancelli (1469–1519), did many monuments including the marble tomb of Ferdinand and Isabella in the Cathedral of Granada. Among other Italians who worked in Spain later in the century was Leone Leoni (1509–1590). Some of the best Spaniards were trained in Italy, notably the great painter-sculptor Alonso Berruguete (c.1486–1561), a pupil of Michelangelo, who in some ways anticipated the intense manner of El Greco.

The Frenchmen, Jean Goujon (1510?–?1568) and Germain Pilon (1537?–?1590), influenced by Italian artists working for the French court, produced statues and reliefs which were nevertheless quite French in their elegant grace. Goujon's decoration of the Louvre and the *Fountain of the Nymphs,* both in Paris, are typical.

Germans continued their own earlier vigorous tradition modified by a limited amount of Italian influence. This is seen in the bronze work of Peter Vischer (1460?–1529) in his *Shrine of St. Sebald* in Nürnberg, and with more Italian traits, in the work of Peter Flötner (c.1485–1546) and Konrad Meit (c.1480–c.1550) of the same period.

Baroque Sculpture.—Baroque sculpture of the 17th and 18th centuries, despite its essential architectural function, was replete with lively movement and pictorial in nature. Figures moved, flew, or were contorted in agony. Abundant draperies fell in tortured folds or were swept by the wind. Figures in histrionic poses were made more dramatic by vivid light and dark contrasts produced by pronounced undercutting or deep indentations.

The greatest master, one whose work sums up the chief characteristics of the period, was Giovanni Lorenzo Bernini (1598–1680). His great *Shrine for St. Peter's Chair,* his huge, bronze *baldacchino* over the high altar, his theatrical tombs for Urban VIII and Alexander VII, together with sculpture of the same nature by followers, give life and vigor to the interior of St. Peter's in Rome. The impressive colonnaded piazza in front of the same basilica was also designed by Bernini and embellished with 140 colossal statues from his studio. His many fountains of fanciful design, such as those of the Piazza Navona, help to give Rome its unique character. His theatrically conceived Cornaro chapel in Santa Maria della Vittoria, Rome, with its *Vision of Santa Teresa,* is a masterpiece which magnificently defies all the logical properties of stone. Bernini's portrait busts, for example that of Louis XIV (at Versailles), are realistic, intensely alive, and at the same time grandiloquent in pose and exaggeration of drapery. The prestige of Bernini and the force of his art were so great that his style was imitated not only by his contemporary rivals such as François Duquesnoy (1594?–1642) and Alessandro Algardi (1602–1654), but by most Italian sculptors through the greater part of the 18th century. The famous *Trevi Fountain* in Rome, for example, was done by Pietro Bracci (1700–1773) following a drawing of Bernini.

French baroque sculpture, like the painting of the time, maintained a stronger element of the classic than the Italian. Nevertheless, Bernini's influence was felt. Antoine Coysevox (1640–1720) and François Girardon (1628–1715) produced classicizing garden and fountain sculpture for the park at Versailles, dramatic tombs for the regent cardinals (that of Richelieu by Girardon, that of Mazarin by Coysevox), and lifelike portrait busts somewhat in Bernini's flamboyant manner. Their decorative reliefs in the Louvre and at Versailles also manifest influence of the great Italian. Though France produced no sculptor of quite the rank of Bernini, the quality of French baroque sculpture was remarkably high, especially in the 18th century. Guillaume Coustou (1677–1746), Edmé Bouchardon (1698–1762), Jean Baptiste Lemoyne (1704–1778), Jean Baptiste Pigalle (1714–1785), Étienne Maurice Falconet (1716–1791), Jean Jacques Caffiéri (1725–1792), Augustin Pajou (1730–1809), and Claude Michel, called Clodion (1738–1814), were all so equally good in a wide range of subjects that it is difficult to single out any one of them as outstanding. Their sensitive and refined, yet lively, works, are so imbued with naturalism that they seem almost timeless.

German baroque sculpture drew inspiration from both France and Italy, but was essentially German in its nervous energy and powerful forms. This is seen in the equestrian statue of the great elector in Berlin by the Italian trained Andreas Schlüter (1664–1714). More of the classical, French taste is perceptible in the New Market Fountain by Georg Raphael Donner (1693–1741) in Vienna. But the most characteristic phase of sculpture of the period is the rich decoration of palaces and Roman Catholic churches by countless wood carvers and masters of stucco. Superb examples may be seen in the Church of St. George at Diessen and in the pilgrimage Church of Vierzehnheiligen.

Spanish sculpture was almost independent of the pervading influence of Bernini, but was indebted, as was Spanish painting of the time, to the great Italian realistic painter, Michelangelo da Caravaggio (c.1565–1609). The characteristic medium was wood, painted most realistically. Important carvers were Gregorio Fernández (1566–1636), Juan Martínez Montañés (1568–1649), Alonso Cano (1601–1667), and Pedro de Mena (1628–1688).

The 19th Century.—Neoclassicism, which had been developing during the second half of the 18th century, was, in part, a reaction against the excesses of the baroque. In part, it was the result of a new wave of enthusiasm for the classic which had been aroused by the rediscovery of Pompeii (1748) and Herculaneum (1737), cities buried by the ashes and volcanic mud of Vesuvius in the 1st century A.D. Knowledge of the startling discoveries was spread by detailed catalogues and engraved plates. Scholars, notably Johann Winckelmann (1717–1768), and amateurs analyzed ancient art. The qualities which they found admirable in antique art became the basic principles of neoclassicism. Idealization, or generalization, replaced realism. Classic repose supplanted baroque agitation. "Noble simplicity," a catch phrase from Winckelmann, became the cardinal principle of all art. Under its authority the rich compositions, the high emotional content, and the vivid contrasts of light and dark of the baroque, were condemned. Sculptors turned to Greek and Roman statues and reliefs as models of perfection

to be emulated. Classical togas and classical nudity replaced the representation of contemporary costume. And classical subjects, particularly of the noble deeds of heroes from ancient history and mythology, became favorite themes, wrought with meaning to the educated people of the time, and impressive even to the illiterate.

Because of its development of philosophy, the natural sciences and religious skepticism, the 18th century is often known as "the age of reason." To people of such a period it was only natural that art which could be reduced to principles, a rational art, would be appealing. But the 18th century was also a period with a strong vein of what might be called the irrational: modern romanticism was then a flourishing infant, and sentimentality was rife. To the romantic and the sentimentalist the new classicism also appealed. People began to lead a kind of masquerade life. By 1800 women dressed their hair in antique coiffures and dressed their bodies in antique costumes. People went to church in Greek temples and lived in rooms furnished in imitation of Pompeii. There was an identification between the new republicanism of France and America and the republicanism of ancient Rome and the democracy of Athens that gave a deep sentimental meaning to the use of the classic in art. There was no questioning the suitability of Roman architecture for Washington, the capital of a new republic. Later, Napoleon with his new empire, found the same kind of parallel with imperial Roman art.

Neoclassic art varied little from country to country; adherence to its rigid standards permitted little latitude even for the personal expression of the artist. It is not surprising then that the two most admired sculptors of the style came at its inception, that both had practiced in the old baroque-rococo tradition. In France, Jean Antoine Houdon (1741–1828) was one of the greatest of all portrait sculptors. All of his portraits are so infused with life that they tell us not only what people looked like but what they were. Such a work is the head of Benjamin Franklin in the City Art Museum, St. Louis, from 1778. Such also are the *Seated Voltaire* in the Comédie Française, Paris, and the statue of Washington (1785) in the State House at Richmond, Va. Realism in portraiture, because of the sanction of that factor provided by realistic Roman examples, continued from the baroque into the neoclassic. About 1780, however, signs of greater quietness of pose appear, and often, as in the *Seated Voltaire* done at that time, the garb is classic. At the same time Houdon did his most famous nonportrait work, the marble *Diana* of the Hermitage in Petrograd (a terra cotta version is in the Frick Gallery, New York), which is not only classic in subject but likewise classic in facial type and the idealization of anatomical features. The second great imitator of the style in sculpture was Antonio Canova (1757–1822), whose international fame made Rome the mecca of younger sculptors. He adopted neoclassic tenets after moving to Rome from Venice in 1779. Since he did relatively few portraits, the variety of his work is much greater than Houdon's. Canova left many tombs, from small, delicately executed stelae to the huge pyramidal tomb of the Archduchess Maria Christina in Vienna, with its allegorical procession showing that all paths lead but to the grave. His best known work is the sentimental group, *Cupid and Psyche,* in the Louvre, which seems to have been inspired by a painting from Herculaneum. His huge, and powerful, bronze statue of Napoleon as Mars (in the court of the Palazzo Brera, Milan) is typically neoclassic in its allegory and nudity. A third inaugurator of neoclassicism was the Englishman, John Flaxman (1755–1826), who was more famous for his decoration of Wedgwood pottery and his linear drawings than for large-scale sculpture. Already as early as 1775, when he began to work for Wedgwood, his manner was completely neoclassic. Another early practitioner of the new style was the German, Johann Heinrich von Dannecker (1758–1841), whose sculpture resembles Canova's. More original was Johann Gottfried Schadow of Berlin (1764–1850), who decorated the Brandenburg Gate in Berlin with rather dry neoclassic sculpture, but whose work in general, like the portrait group of the *Crown Princess Louise and her Sister* (Berlin), exhibits an admirable balance between naturalism and classic grace. The Dane, Bertel Thorvaldsen (1768–1844), enjoyed a reputation second only to that of Canova in his own day. His rhetorical variations of classical forms and themes are perfect examples of the vacuity of expression, which, alas, was all too frequent in neoclassic art and which is felt in the work of countless sculptors in the first half of the 19th century.

By about 1830 many sculptors began to deviate from the strictures of neoclassicism. Lorenzo Bartolini (1777–1850) preached unmitigated realism, but carved figures, as in the public Monument to General Demidov (Florence), which preserve neoclassic costume and nudity and have only a mild infusion of naturalism. Though he himself could not attain realism, Bartolini in 1842 gave unstinted praise to the starkly lifelike statue, *Abel* by Giovanni Dupré (1817–1882), whose works were inspired by nature and Early Renaissance sculpture. In France, François Rude (1784–1855) respected the neoclassic credo but could not stay within its bounds. As early as 1833 his *Neapolitan Fisher Boy* was hailed by some critics as romantic in subject and realism. His famous *Departure of the Volunteers* on the Arc de l'Étoile, Paris, used classical types and costumes but was quite opposed to the neoclassic in its intensity and movement. A greater break from his neoclassic training was made by Antoine Louis Barye (1795–1875) in 1831 when he exhibited the *Tiger Devouring a Crocodile* (in the Louvre) which was not only vividly realistic, but of a kind of subject outlawed by neoclassicism for monumental art. In 1837 Barye, rebuffed by the classicistic critics, began to produce statuettes, candelabra, clocks, etc., using his favorite motifs of wild animals. In the 1850's he returned at times to classical themes like the *Centaur and the Lapith* (Museum of Puy) but not to a neoclassic manner.

By 1850 neoclassicism was moribund. Young sculptors were no longer fettered by its principles and strictures. Instead, they turned to nature directly or drew inspiration from the great masters of the Renaissance and baroque periods. The Englishman, Alfred Stevens (1818–1875), though he studied for a year with Thorvaldsen, was never a neoclassicist. His decorative sculpture for Dorchester House in London (1858–1862) reminds one of the full-bodied figures and expressive poses of Michelangelo. His monument of the duke of Wellington in St. Paul's Cathedral, London, is one of

the sculptural masterpieces of its century. A nephew of François Rude, Emmanuel Frémiet (1824–1910), following the lead of Barye, devoted his talents chiefly to the modeling of animals. His most lasting success derives from a notable series of bronze equestrian monuments, such as the *Joan of Arc* in the Place de Rivoli, Paris, which, while meticulous in realism of anatomy and historical trappings, avoids the triteness of many of his other works. Of a surer taste are the exuberant, energetic works of Jean Baptiste Carpeaux (1827–1875) inspired by the spirit of 18th century French art. To appreciate Carpeaux to the full one should look at the terra cotta *Flora* (in the Louvre) and the plaster model of the *Dance* (in the Louvre) rather than the marble version on the façade of the Opéra. Paul Dubois (1829–1905), after a sojourn in Florence, adopted features of Early Renaissance sculpture. The delicacy and spirituality of that period appears in his bronze *Young St. John the Baptist* (Luxembourg Museum, Paris). Jules Dalou (1838–1902), who in his full forms and salubrious carnality reminds one of his contemporary, the painter Renoir, revoked the spirit of Rubens in great bronze groups of Silenus (Luxembourg Gardens, Paris), and the Republic (Place de la Nation, Paris). The German, Reinhold Begas (1831–1911), also drew inspiration from the rich fancy of baroque art in his fountain near the Royal Palace in Berlin. His work lacks the vitality of Dalou.

(François) Auguste Rodin (1840–1917) was the outstanding original genius of French 19th century sculpture. He used stark realism at times, he borrowed extensively from the art of the past, and he was a modeler who gave his plaster models to be reproduced by others in marble or bronze. Yet, though he had these things in common with nearly all 19th century sculptors, his work from the beginning rang as new and different. In modern sculpture, Rodin almost by himself, occupied a place as forerunner parallel to that of the entire group of Impressionists and Post-Impressionists in the field of painting. When shown in the Paris Salon of 1877, Rodin's first important work, the *Age of Bronze,* was taken to have been a cast from the body of a living man. It and his *Preaching Saint John the Baptist* (1879) may be considered the pre-eminent realistic statues of the 19th century. In them one detects influence from Donatello's late work in the exalted expressions and broken surface treatment. In 1879 Rodin began a huge portal with many figures and reliefs known as the *Gate of Hell,* which, though never completed, served as a source of themes for many of his later works, including his best known creation, the *Thinker,* a tribute of his admiration for Michelangelo. In his latest sculpture, like the statue of Balzac, Rodin exaggerated nature much like the great cartoonist, Honoré Daumier (1808–1879). The power of his figures and the poetic, emotional content of his works won Rodin fame in his day, but his enduring fame will rest rather on his realization of sculptural form as expressed in the myriad of telling outlines generated by any one of his mature works, and in the almost musical harmony produced by the undulation of his modeling as forms move into each other to create a whole Also, in spite of the fact that Rodin's models were put in stone or bronze by others, the finished works manifest a new sense of fitness to their materials even when, like the *Thinker,* they were reproduced both in bronze and marble. The Musée Rodin in Paris houses the sculptor's original casts.

A German sculptor, Adolf von Hildebrand (1847–1921), was second in importance to Rodin in affecting the course of 20th century sculpture. Hildebrand's approach to sculpture was intellectual; indeed at times so calculated that much of his work lacks the intuitive spark of inspiration which one demands in art. He turned from realism and baroque turbulence to Greek repose, even seeking impassivity of expression that he might accentuate formal qualities. His marble *Male Nude* (National Gallery, Berlin) from 1883 to 1884 is the most characteristic incarnation of his theories. The head is merely one of the anatomical details of the figure. While natural in proportion and relationship, the parts of the body and head were simplified and resolved into essentially geometric forms. The relationship of the figure to the block of marble from which it was carved was made evident to emphasize the nature of the material, to produce the desired glyptic (or stonelike) quality. Surfaces were smooth to enhance the beauty of the material.

The 20th Century.—At the very beginning, 20th century sculpture was revolutionary, especially in France, where the genius of Rodin had created new concepts of the nature of sculpture. What the younger artists learned from Rodin was, above all, that the essence of sculpture derives from the relationship of masses to masses, and then from the outlines generated by those masses. Hildebrand was also influential in his classicism with its insistence on repose; in his tending to geometrize which led to the simplification—or abstraction—of nature; and in his emphasis on respect for the nature of the materials used for sculpture. In respect for materials, Hildebrand's influence coalesced with more important developments of the same line of thought that had occurred in the fields of architecture and the minor arts, and that had already had effect in painting, particularly in the painting of Eugène Henri Paul Gauguin (1848–1903).

Aristide Maillol (1861–1944), trained as a painter and self-taught as a sculptor, rebelled from Rodin's expression of movement, especially in surface treatment. His *Seated Woman* (in plaster about 1901, a marble version is in the Garden of the Tuileries, Paris) is quiet and massive with an emphatic definition of geometric form. The facial type, the smooth roundness of the modeling, and the simple, continuous outlines derive from ancient Greek sculpture of the early 5th century B.C. His later work follows in the same path: feminine figures in restful or heroic poses with reminiscences of Greek classic art. The work of Joseph Bernard (1866–1931) might be described in much the same terms, but Bernard, though not so well known as Maillol, far surpassed the latter in variety of subject and treatment, and also in infusing life into his figures. His bronze *Maiden with a Jug* (in the Luxembourg Gardens) has the musical rhythm of Greek work embodied in its simple, harmonious forms. Bernard's figures in marble manifest an extraordinary sensitivity to the medium. Their pagan sensuousness reminds one of the finest of Renoir's paintings of the nude. Bernard carved directly; that is to say, without the use of a clay or plaster model. Émile-Antoine Bourdelle (1861–1929) and Charles Despiau (1874–1946) were two other sculptors of the same general classicizing tradition, who retained a bit

more of Rodin's love of surface manipulation and admiration for Gothic sculpture.

In Germany the rationality of Hildebrand resulted in a development of powerful architectural sculpture, largely under the direction of the architect, Bruno Schmitz (1856–1890). For the latter, Franz Metzner (1870–1919) executed the highly stylized, and architecturally controlled, sculptural decorations of the Leipzig Monument of the Battle of Nations (1906–1913). A pupil of Metzner, the Yugoslav, Ivan Meštrović (b. 1883) enlivened and enriched his master's architectural stylization with motifs and energy inspired by Michelangelo and Rodin. The most talented German sculptor of the first generation of the century was Wilhelm Lehmbruck (1881–1919), a pupil of Maillol, whose *The Kneeling Woman* (a cast stone version is in the Museum of Modern Art, New York), like most of his figures, combines classic repose and medieval elongation with most expressive results.

In England the American born Sir Jacob Epstein (1880–) has practiced in two distinct manners, one for bronze and quite another for stone. His works, therefore, are interesting examples of the 20th century sculptor's sharp distinction between modeling and carving. Epstein's bronzes, like those of the elderly Donatello whom he admires, are rough in surface and exaggerate natural forms, yet produce an effect of realism. His *Madonna and Child*, and the *Risen Christ* (both in the Tate Gallery, London) are outstanding examples of modern religious art. Epstein's stone sculpture, simple in outline and smooth in surface, has the qualities of direct carving.

Adolf Gustav Vigeland (1869–1943), whose work is seldom seen outside his native Norway, was perhaps the most original of Rodin's disciples. His manipulations of special effects have interested younger sculptors in many lands. Carl Milles of Sweden (b. 1875) has been unequaled in the production of large-scale decorative sculpture in bronze. The power and charm of his work may be appreciated in numerous works at the Cranbrook Academy, near Detroit, where he taught for several years.

All of the above leaders in sculpture of the 20th century insisted upon a respect for materials and all of them produced figures—chiefly of the human nude—which are recognizably natural but not realistic in the 19th century sense. A somewhat younger group of sculptors under the influence of cubism and later revolutionary developments, shunned naturalism and, to a great extent, the human subject. Pablo Picasso (b. 1881), one of the inventors of cubism, has made sculpture similar to his ever-changing painting since 1905. A bronze *Head of a Woman* (Art Institute, Chicago) distorts human features into angular cubic forms just as do his paintings from 1909. Within the next three years a number of youthful, traditionally trained sculptors followed the lead of Picasso. Raymond Duchamp-Villon (1876–1918), pupil of Rodin and influenced by Maillol and German sculpture, about 1912 renounced naturalism for abstraction. His bronze *Horse* (Museum of Modern Art, New York) from 1914 is an organically generated assemblage of geometric forms expressing the beat of a horse's hoofs as no naturalistic statue ever had. Umberto Boccioni (1882–1916), one of the founders of the Italian movement of futurism, transposed parts of the human body and used inexplicable applied or interpenetrating objects to produce effects of weirdness and movement. His *Unique Forms of Continuity in Space* from 1913 may be seen in the Museum of Modern Art, New York. Constantin Brancuşi (b. 1876), a Rumanian domiciled in Paris, while influenced by the abstract direction of cubism, was creating his own completely different abstractions as early as 1908. His repertory of geometric and organic creations is best studied in the Arensberg Collection of the Philadelphia Museum, which has, among others, his blocky and glyptic *The Kiss* from 1908, and three versions of his *Bird*. Hans (Jean) Arp (b. 1887), an Alsatian, has made smooth organic sculpture in the round similar to Brancuşi's but is especially known for his reliefs which often consist of nothing more than flat pieces of wood of squeezed ovoid outline, pasted to a board. Henri Laurens (1895–1954), a Frenchman, worked in much the same way but with added color and a variety of planes and shapes. The Russian born Aleksandr Porfirievich Archipenko (b. 1887) went to Paris in 1908 where within a few years he began to develop sculpture of cubist inspiration. His later work (since 1924 he has lived in the United States), lies between naturalism and abstraction. The Russian born brothers, Naum Gabo (b. 1890) and Antoine Pevsner Gabo (b. 1890) early developed cubism into opposing planes in space, then went on to produce purely nonobjective construction which resembles complicated mathematical projections, using wire, plastics, and other nontraditional materials. Jacques Lipschitz (b. 1891 in Lithuania) has been one of the most imaginative of French sculptors to evolve out of cubism. The variety of his forms and modes of expression are unequaled in 20th century sculpture. About 1930 his cubistic creations began to elicit weird, haunting effects. Since that time his sculpture has been largely representational in a fantastic vein. Though his work is usually in bronze his effects in the handling of that material are astonishingly varied. The Spaniards, Pablo Gargallo (1881–1934) and Julio Gonzalez (1876–1942), were important in establishing wrought iron as a medium for sculpture. Gonzalez, after working with Picasso about 1930, began to make constructions in an original fantastic vein. Italian sculptors, with the exception of Boccioni, worked in a simplified traditional manner until the 1930's, when Arturo Martini (1889–1947) and his pupil Marino Marini (b. 1901) evolved new expressive factors of distortion. Marini's weathered surfaces, and surface tensions, together with the Etruscan sepulchral aura which he creates, have brought him great fame.

Of all English sculptors of the century, Henry Moore (b. 1898) is most eminent. Influenced by Brancuşi, Picasso, and Epstein, his art is, nevertheless, highly original in its evolving forms and its recognition of the quality of materials. In the latter respect, Moore is unequaled, especially in the treatment of many different kinds of wood and stone. His favorite subject is the reclining female nude, represented abstractly with marked distortions The Swiss Alberto Giacometti (b. 1901) has attracted worldwide interest in his emaciated little figures of molten bronze, with which he creates extraordinary special effects by using a kind of horizontal relief setting.

American Sculpture.—Sculpture, recognized as art, did not exist in colonial America due to

the prejudice of militant Protestantism against the making of idols. In the 18th century, there were, however, anonymous carvers who made ship figureheads, weather vanes, and other objects which are now cherished as examples of folk art. With the birth of the new republic coinciding with a more broadminded concept of religion, there developed a real need for sculpture to commemorate heroism and to embellish monumental buildings. This need was first met by foreigners and self-trained artists. John Frazee (1790–1852), a stone-cutter, executed the first marble busts in this country. William Rush (1756–1833), a Philadelphia physician, with a modicum of instruction from the Englishman Edward Cutbush, carved ship figureheads which Benjamin Latrobe praised as peerless. He also carved busts and allegorical figures in wood. His best known work was the *Nymph of the Schuylkill,* preserved in a bronze replica in the Philadelphia Museum.

Young Americans, trained in Italy, were producing sculpture in a belated neoclassic style shortly before the middle of the 19th century. From that time on, sculpture in America followed the same general path of development as in Europe. Horatio Greenough (1805–1852) was the first academically trained American sculptor. He went to Rome in 1825, studied under Thorvaldsen, then in 1828 settled in Florence where he lived most of his life. His *Seated Washington* (now in the Smithsonian Institution), though a powerful, nobly conceived figure, became the butt of jokes because people in the 1840's, and especially Americans, could no longer regard as serious the portrait of a modern man as Zeus, naked to the waist. Hiram Powers (1805–1873) followed Greenough to Florence in 1837 and began to work in the same late neoclassic manner. Powers, however, enjoyed enormous success because his statues of the female nude combined the right amount of classic generalization with touches of realism to titillate, but not shock, contemporary taste. His *California* (in the Metropolitan Museum, New York) is a good example. Thomas Crawford (1813?–1857), after training in Rome, received commissions for the Capitol in Washington, D.C. His bronze *Armed Freedom* crowns the dome. Also he did the pediment of the Senate wing and the bronze doors of the Senate Portico. Another group of somewhat younger artists, including William Wetmore Story (1819–1895), Randolph Rogers (1825–1892), William Henry Rinehart (1825–1874), and our first prominent woman sculptor, Harriet Goodhue Hosmer (1830–1908), also studied in Italy and produced rather Victorianized neoclassic works almost to the end of the century.

In the meantime some other sculptors, as in Europe, adopted a more realistic attitude. Erastus Dow Palmer (1817–1904) infused life into neoclassic themes with a charmingly awkward naturalism and a caressingly soft handling of surfaces. Henry Kirke Brown (1814–1886), like his contemporary Emmanuel Frémiet in France, won fame for his equestrian monuments, of which the Washington (Union Square, New York) is his greatest achievement. John Quincy Adams Ward (1830–1910), a pupil of Brown, continued the latter's realistic approach with the harsh definition of steel engravings in a host of public monuments. Far the greatest of the realist trend was the Boston physician, Dr. William Rimmer (1816–1879), who demonstrated in words and in sculpture the clearest concept of the art. The vigor of his works, their organic coherence, and their realization of sculpture's multiplicity of outlines, make them rival the finest of Hellenistic sculpture. His *Falling Gladiator* of 1861 illustrates an early stage of his ability to transform a profound knowledge of anatomy into expressive form, an ability which reached a zenith in *The Dying Centaur* of The Metropolitan Museum of Art, New York. He also carved directly in granite a nobly tragic head of St. Stephen.

Sculptors of the last generation of the century went to school in Paris, where they acquired the more pictorial manner and eclectic qualities of their French masters. This is illustrated in one of the bronze doors of the Library of Congress building in Washington, D.C., modeled by Olin Levi Warner (1844–1896), and even in the work of the most famous American sculptor of the century, Augustus Saint-Gaudens (1848–1907). His first work after his return to America, the *Admiral Farragut* (1874) in Madison Square, New York, showed an inventiveness in design and a mastery of composition hitherto unknown in America. His statues of Lincoln, particularly the *Standing Lincoln* in Lincoln Park, Chicago, and his *Deacon Chapin,* or *The Puritan,* are so perfectly characterized and strongly presented that they have become part of America's visual heritage. His unequaled modeling in very low relief is readily appreciated in a series of bronze portrait plaques, of which those of Robert Louis Stevenson are best known.

Many sculptors in America, as elsewhere, carried the 19th century attitudes well into the 20th century. Daniel Chester French (1850–1931) continued, with great acclaim, a weak adaptation of Saint-Gaudens' style. George Grey Barnard (1863–1938) was more original. He, like Rodin, whose works Barnard's often resemble, was an admirer of Michelangelo. His early *Two Natures* (in the Metropolitan Museum, New York) was inspired by the great Italian but has Barnard's mysticism. The success of his heroic attempts to achieve monumentality may be judged in the two groups which flank the entrance to the capitol at Harrisburg, Pa. Another great personality, who like Barnard attempted the monumental, was Lorado Taft (1860–1936), known for his *Fountain of Time* (in the Midway, Chicago) and his colossal *Black Hawk* (in Oregon, Ill.) both in cast concrete. Cyrus Edwin Dallin (1861–1944) successfully adopted the realistic manner of Frémiet to the theme of the Indian on horseback. The same was done with more originality by Solon Hannibal Borglum (1868–1922), whose brother Gutzon Borglum (1871–1941) was one of the Americans inspired by Rodin. Gutzon will be remembered for the gigantic heads of national heroes which he carved in the living rock of Mount Rushmore, in the Black Hills of South Dakota. Jo Davidson (1883–1952) did portraits of great sensitivity in character delineation and in the handling of bronze. His marble *Japanese Girl* (Whitney Museum, New York) achieves a wistful poetic effect with very simple means.

Just before the outbreak of World War I an exhibition of European contemporary art was exhibited in the United States. The Armory Show, as it has been called, opening in New York City on Feb. 17, 1913, created a furore because it brought to the attention of Americans the most

advanced products of the cubists and other revolutionary artists. From this time on, whether an artist liked abstraction and distortion or not, he could not ignore their existence. Elie Nadelman (1885–1946) came to the United States from Poland in 1917, and remained. His extremely rounded doll-like figures are so simplified that, though usually not distorted in proportions, they produce strange, unnatural effects. Gaston Lachaise (1882–1935) was perhaps the first American sculptor to be considered an extremist in his deviation from naturalism. His *Floating Figure* from 1927 and *Standing Woman* from 1932 (both in the Museum of Modern Art, New York) exaggerated the female figure to achieve impressive heroic effects.

Paul Manship's (b. 1885) studies of the classic and Renaissance in Europe influenced his style. His work is characterized by conscientious craftsmanship and harmonious composition. He has done many bronze groups, like the *Dancer and Gazelles* (Corcoran Gallery, Washington, D.C.), which combine the human figure with animals. José de Creeft (b. 1884) and William Zorach (b. 1887) employ a simplified naturalism and emphasize the beauty of the material of their work, even seeking the effect that the material has generated the sculpture itself. Zorach has produced strongly modeled and emotionally effective works, especially in granites and other hard stones. John B. Flannagen (1898–1942), with similar aims, carved animals out of boulders. His *Triumph of the Egg* from 1937 is a genial specimen. Hugo Robus (b. 1885) is best known for the clever and effective *Girl Washing Her Hair* (Museum of Modern Art, New York) from 1933, which, while basically natural, is almost surrealist in effect. Alfeo Faggi (b. 1885) turned from a manner adapted from the early Renaissance to a kind of abstraction which seems almost Byzantine for his *Stations of the Cross* in Saint Thomas the Apostle, Chicago.

Robert Laurent (b. 1890) has turned from classical concepts similar to Maillol's to abstractions in which natural forms are stylized rather cubistically. Something of the same is true of the work of Berta Margoulis (b. 1907) and of Concetta Scaraglione (b. 1900), though a fine feeling for classic form and solidity has not disappeared completely in the latter's work. The strength and sensitivity of Dorothea Greenbaum (b. 1893) has also persisted through more modern stylistic phases. Among so many fine women sculptors (and there are others that space forbids consideration) perhaps the outstanding is Minna Harkavy (b. 1895) whose bronze *American Miner's Family* (Museum of Modern Art) is one of the most original and most expressive American works of art. Her much later, prize-winning *Two Men* from 1951 creates an aura of long past times in its powerful expression. William McVey (b. 1905) might be characterized as an abstracting naturalist who has come under the influence of Aztec sculpture. His figures, like *Vision Wichita,* are strongly rounded with textured, or sometimes almost weathered, surfaces. Chaim Gross (b. 1904) fits in no category. His blocky forms disclose a strange race of blocky girls in surprising poses.

A great number of the most talented American sculptors who developed in the 1930's have turned to extreme forms of abstraction, or even nonobjectivity. The oldest and most famous American extremist is Alexander Calder (b. 1898), the son of a well-known sculptor of the early part of the century, Alexander Sterling Calder. Young Calder went to Paris in 1936 where he made quite a reputation with his portraits in wire and his animated *Circus* with animals and acrobats cleverly constructed of wire and wood. Then about 1930, influenced by Pieter Cornelius Mondriaan (1872–1944), he designed three dimensional nonobjective compositions out of wire and sheet metal. These are called "stabiles." Soon he had worked out schemes for animating or giving motion to these creations. By 1932 the idea of his "mobiles" was realized, and Calder had made what is doubtless the most important contribution to nonobjective art of any American sculptor. A good example of a wind-turned mobile is his *Lobster and Fish Tail,* commissioned for the stairwell of the Museum of Modern Art in 1939. Many of the younger men were strongly influenced by the constructionists, especially by the work of Naum Gabo, who settled in the United States in 1947. The very geometric constructions of wire and rods by Richard Lippold (b. 1915) are usually pure examples of constructionism but sometimes Lippold inserts small figures which create a romantic, stage-set effect. Theodore J. Roszak (b. 1907) in the early 1940's did constructionist works influenced by Mondriaan and Alexander Calder, but later eschewed what he calls "a technological deity" in favor of savagely emotional creations of animal-like forms somewhat resembling the late work of Jacques Lipschitz. His medium is usually welded bronze. Somewhat similar, though more geometric and less emotional, is the work of David Smith (b. 1906). Experimenters in pure form, often biomorphic, are José Ruiz de Rivera (b. 1904), David Hare (b. 1917), and Ibram Lassaw (b. 1913). Isamu Noguchi (b. 1904), although an American and trained as an assistant by Brancuşi, makes designs which have a Japanese flavor. Some of them are for furniture. Herbert Ferber (b. 1906) worked in a manner influenced by Julio Gonzalez, then developed a peculiar, personal expression by composing thornlike bits of metal with almost anguishing effect.

There is no doubt that the meaning of sculpture must be extended to comprehend the constructional and biomorphic forms of the 20th century and the new materials and techniques which have been used to produce them. On the other hand, the representation of natural forms in a more-or-less traditional manner continues. There is need for both, and each may be fine in its own way.

SCUP, one of the names of an important American food-fish (*Stenotomus chrysops*) belonging to the family Sparidae, to which the sheepshead and snapper also belong. It is known among fishes inhabiting the same region by its deep body, prominent dorsal spines, and the canine-like teeth. The color is silvery gray with purplish reflections above, pure silvery on the sides below. This fish is abundant from Cape Cod to the Carolinas and reaches a large size on rocky ledges where food is abundant, though ordinarily not exceeding 9 or 10 inches in length; it reaches a remarkable size at the age of two years. In the South it is known popularly as porgy. Consult Goode, G. B., *American Fishes,* (New York 1888); Jordan and Evermann, *American Food and Game Fishes,* (New York 1902).

SCURVY, a disease resembling purpura, characterized by inanition, anemia, asthenia, ecchymoses and a tendency to swelling and bleeding of the gums. It is mainly due to disordered nutrition from improper food. Sometimes it follows a deficiency of fresh vegetables and fruits, or an excess of salt fish and pork, the use of tainted food, a too monotonous diet, or an insufficient amount of food. General ill health and malnutrition, and a cold, damp winter, compelling persons to house themselves, are predisposing causes. No condition of the blood differing from that found in other anemias has been recognized. Some believe that the disease is an infection because it has often spread rapidly in prisons, workhouses, etc., and sometimes has a distinct period of incubation, and because one attack, as a rule, confers immunity. It is not related to relapsing fever, which is contagious.

Up to the middle of the last century scurvy was frequent during wars, pestilences and famine, and especially on long sea-voyages when the diet consisted largely of bread, tea and salt meat. During the Crimean War 23,000 cases of scurvy occurred among the French troops alone, and in the American Civil War 15 per cent of the deaths were from this disease, though many cases recovered, owing to the use of vegetable food furnished by the Sanitary Commission. At the present time scurvy is comparatively rare, as most vessels going on long voyages are supplied with a variety of anti-scorbutics, canned meats, lime-juice, lemons, and other fruits, vegetables, etc., and on land, in civilized countries, or at least where hygiene is not rudimentary, fresh fruits and vegetables are more used than formerly.

In scurvy the blood coagulates poorly, its red corpuscles are diminished, while the white are increased in number. Sometimes there is edema of the feet and ankles and serous exudation into the pleural and large joint cavities. There are purpuric spots in the skin, especially on the legs, ecchymoses in the pleura, pericardium, cerebro-spinal meninges, synovial membranes and in the mucous lining of the bronchi and alimentary canal; and haematoma in muscles like the gastrocnemius and gluteus, which may suppurate or in part organize. The gums are swollen, especially about the teeth, and their deeper layers are thickened; fatty changes occur in the liver, spleen, kidneys and heart; the bones may be carious or fractured; and the bone-marrow and mesenteric glands may display hemorrhagic infiltration. In infants the ecchymoses are almost entirely subperiosteal, the blood raising the periosteum (usually of femur, sometimes of tibia or fibula, rarely of the bones of forearms or other parts) in a fusiform swelling, surrounding the bone. The bones become thickened and sometimes superficially necrosed. The epiphyses may separate. The gums may be spongy.

The symptoms of scurvy, which usually develop slowly, include lassitude, anemia, flaccidity of muscles, a cool, dry skin, with sometimes a yellowish pallor. When the disease is developed the gums are red, nodular or fungous, and bleed readily. When the disease is advanced, hemorrhage occurs internally or externally, the breath is offensive, the gums ulcerate, and the teeth loosen. There is thirst, with a craving for sour food and condiments; the joints are swollen and painful; syncope, dyspnoea, and pulmonary congestion are common; the urine is scanty, high-colored, and less than normally acid; the temperature is subnormal (96°F. or 97°F.). The patient is pale, feeble, much emaciated, mentally depressed, and may have low delirium and coma. Meningeal hemorrhage may cause convulsions or hemiplegia. In infants, over the inflamed periosteum there is intense pain and tenderness, swelling and a tense, shiny skin. The child screams when moved, loses appetite, emaciates, grows pale and feeble, perspires freely. There is usually diarrhoea, sometimes hematuria, hemorrhagic blebs in the pharynx, and extravasation of blood in the orbit. Other extravasations, however, are rare. The present day attitude is to regard scurvy as a disease due to the deficiency of certain ingredients in the diet. These are usually chemical or nitrogenous phosphorus compounds, often called vitamins.

SCUTAGE, or **ESCUAGE,** in the feudal system the fee on payment of which the military service due from the holder of a knight's fee was not exacted. It originated about the 11th century, and the irritation caused by its exaction was one of the causes that moved the barons to oppose King John in 1214. Consult Baldwin, J. F., *The Scutage and Knight Service in England* (Chicago 1897).

SCUTARI, (1) town, and (2) prefecture, in Albania, and (3) lake, partly in Albania and partly in Yugoslavia. The town, which the Albanians call Shkodër, is situated near the south-east end of the lake. It trades wool, hides, tobacco, and dried fish for foodstuffs, textiles, and metal goods, and manufactures cotton and firearms. In addition to its airport and ancient citadel, it has picturesque mosques, and a Roman

Catholic cathedral. Scutari figured for a time as capital of the ancient kingdom of Illyria, but was captured by the Romans in 168 B.C. During the middle ages it was held successively by the Serbians, the Normans, and the Republic of Venice. It was taken by the Turks in 1479, but from the middle of the 18th century its local rulers maintained virtual independence. After the Balkan Wars (1912–1913) it became part of the kingdom of Albania. Occupied by the Italians in 1939, it was freed by unified liberation forces by the end of 1944. Population (1930) 29,209. The prefecture of Scutari, with a population (1930) of 132,336, ranked fourth among the ten prefectures of the kingdom. The lake of Scutari has an area of about 135 square miles. In the north it receives the Morača; and it is drained from the southern end by the Boyana, which, being increased by the main current of the Drin, forms its outlet in the Adriatic.

SCUTARI, Turkey. See ÜSKÜDAR.

SCYLLA, sĭl'a, a character in mythology, the daughter of Nisus, king of Megara, who, when Minos came from Crete to attack Megara, in revenge for the death of his son, Androgeos, was led by her love for Minos to cut off from the head of her father, King Nisus, a purple lock of hair which while it remained on the head of Nisus made it impossible for Minos to take the city. Megara was captured and Nisus slain, and Scylla was either drowned or changed into a fish which Nisus, changed into an eagle, constantly pursued.

Also another Scylla, mentioned in the Odyssey, as a monster with 12 feet, six necks and six mouths, and occupying a rock on the Italian coast. Legends represent her as having been a beautiful woman changed into a monster through the jealousy of Circe or Amphitrite.

SCYLLA and **CHARYBDIS,** ka-rĭb'dĭs, the former a promontory of southern Italy, at the entrance of the strait which divides Italy from Sicily. Navigation around this promontory was considered dangerous by the ancients, but is regarded by moderns as not attended by special difficulty. Charybdis is a whirlpool nearly opposite the entrance to the harbor of Messina in Sicily, the navigation of which is regarded as very dangerous even to vessels of the present age and which must have been extremely perilous in ancient times. "Between Scylla and Charybdis," means to be confined to a choice between two dangerous situations.

According to the Odyssey (xii, 73ff.) these were two sea monsters, personifying the dangers of rocks and eddies. A description of Scylla is given under that heading. Charybdis sat opposite her, on a low rock under a fig tree, sucking in and belching forth, thrice daily, the adjacent water. In the *Alexandreis* of Gautier de Lille occurs the famous line, "Incidis in Scyllam cupiens vitare Charybdim."

SCYTHIANS, the writers of the Classic Age confounded under this name several peoples, who dwelt from the present Rumania to the Pamir across middle Russia and the Caspian steppes. However, the authors who have best described these peoples distinguish the Scythians proper or *Scolotes,* as they called themselves, the immediate neighbors on the north of the ancient Greeks, from the Sarmates who lived to the east of these, and from the Saks who dwelt further east in the land now known as Turkestan.

The Scythians proper occupied from the time of Herodotus the region between Atlas (the present Aluta, tributary of the Danube) on the west and the Tanaïs (the Don or perhaps the Molotchnaïa) flowing into the Sea of Azov on the east. To the south their frontier was marked by the lower course of the Danube from the mouth of the Aluta, and by the Black Sea. To the north their territory extended to the country of the Agathyrces (Transylvania?), to the Neuri in the upper basin of the Dneister and the Bug, and to the Androphages. Altogether they occupy the eastern part of Wallachia, almost all Moldavia, Bessarabia, and the present Russian provinces of Kherson and southern Podolia, and the Crimea, except the mountainous southern portion of the latter, which remained in possession of the savage Tauri. Herodotus divides the Scythians into (1) cultivators, dwelling in the valleys of the Dniester and the Bug, adjoining the Neuri and in the lower valley of the Dnieper and the Panticapée (probably the present Ingouletz); (2) the nomads of the eastern Crimea and south of the mouth of the Dnieper; (3) the Royal Scythians in the eastern Crimea and between the Dnieper and the Tanaïs; (4) the Kallipydes between the Bug and the mouths of the Danube. The Scythians are mentioned for the first time in Hesiod, and many ethnologists are of opinion that their arrival in Europe was about the 15th century B.C. The principal trait of nomadic life—sustenance from asses' milk—is recorded in every ancient description of this people, who were, for the most part, nomads and warriors. Hippocrates gives a detailed description of their mode of life—in four-wheeled chariots, impervious to rain, wind and snow, and often divided into two or three compartments. These chariots were drawn by hornless cattle, the women and children remaining within them while the men accompanied them on horseback. They remained in the same place while there was forage sufficient for their animals, failing which they moved onward. They lived on cooked meats, asses' milk and cheese.

Excellent horsemen, the Scythians hunted and fought on horseback; they were famed as bowmen, but were poor swordsmen. Enemies slain in battle were scalped and their blood drunk from the skulls of others previously slain.

Their religion was a kind of polytheism without external worship. They had no temples nor images of deities to which prayers and sacrifices were offered. The god of war alone had special places reserved for his especial adoration. To him animals and even human beings were offered in sacrifice. Fire worship was general. Women enjoyed a certain amount of consideration due, it is thought, to the legend that the people were descended from a female-warrior race, the Amazons.

The mode of life of the nomadic Scythians led many to a belief in their Mongolian origin. This opinion is, however, no longer held. The little we know of their language, customs and religion leads rather to the conclusion that they were Iraneans. About the second century B.C. the Scythians were conquered by the Sarmates and absorbed by them. Thereafter they dis-

appear from history. Consult Deniker, 'Races of Man'; Ratzel, 'History of Mankind' (1900).

SEA. See Ocean.

SEA-ACORN, or **ACORN-BARNACLE.** See Barnacle.

SEA-ADDER. See Stickleback.

SEA-ANEMONE, a popular name, having reference to their flower-like aspect, for certain polyps or cœlenterate animals belonging to the suborder *Actinaria* of the order or class *Anthozoa.* The sea-anemones are sac-like animals of a more or less cylindrical form, usually fixed by a base or foot to some firm body, and with a disc at the opposite end in which is the slit-like mouth surrounded by whorls of simple hollow tentacles in greater or less number, but nearly always some multiple of six. From the mouth a short tubular gullet or œsophagus reaches into the cavity of the body to the walls of which it is connected by radiating septa or mesenteries, which divide the body-cavity into a corresponding number of sacs, with all of which the œsophagus communicates by a central space into which the septa do not reach. A pair of ciliated grooves or siphonoglyphs extend along opposite sides of the œsophagus and into the corresponding corners of the mouth. These always remain open and are the seat of inflowing and outflowing currents of water, serving a respiratory function as well as for the transportation of waste matter from the body. The body-walls, as well as the tentacles, which are outgrowths from them, are very contractile and largely composed of muscles arranged in a circular and a longitudinal layer, the former serving for purposes of extension, the latter for retraction. These muscles have special relations to the mesenteries. The mesenteries are vertical radiating septa reaching from the mouth disc or peristome to the base, and from the body wall to the œsophagus, but below the level of the latter ending freely. They are not strictly radial in arrangement but are grouped in pairs almost always, like the tentacles, in some multiple of six. The mesenteries corresponding to the siphonoglyphs differ in structure from all of the others and are termed directive; the others form different classes according to the order and degree of development. The inter-mesenteric sacs may further communicate by one or two pores in each mesentery. Along the edges of the septa the testes and ovaries are developed from the cells lining the gastric cavity. Digestive cells are also found in the same region as well as an area filled with stinging thread cells or nematocysts. In some species the latter are found in addition upon delicate threads or acontia which may be protruded through the mouth or cinclides.

Most of the anemones live singly, but some are colonial, in which case they never, like the closely related stone corals, form an internal limy skeleton, but may form a superficial one in the ectoderm. Generally they live attached to rocks or piles, but a few burrow in mud or sand, some as commensals fix themselves to shells inhabited by hermit crabs, etc., and a few are truly parasitic in jellyfishes. All are marine; most sublittoral, some deep-sea and a very few pelagic. They reproduce both asexually by budding and fission and sexually by eggs and spermatozoa, which are usually produced by different individuals. The eggs are fertilized in the gastric cavity and escape from the mouth in most cases as minute free-swimming larvæ or planulæ which soon attach themselves, develop mouth, tentacles and mesenteries, the latter in a definite order, until the adult structure is attained. Sea-anemones are carnivorous, but, having very limited powers of locomotion, are dependent upon such food as falls upon the expanded tentacles and peristome. This is captured through the paralyzing effect of the stinging cells or engulfed by the enfolding tentacles and passed through the mouth into the gastric cavity for digestion, the undigested portion being rejected through the mouth. They will devour a surprising quantity of food and grow rapidly; and if starved, gradually shrink to almost the point of disappearance without losing their form. The species are quite numerous and are chiefly distinguished by the arrangement of the septa and tentacles, with color, form, etc., as minor characteristics. Most of them and particularly the tropical forms are beautifully colored. A large, handsome and variable species very common on the rocky shores of New England is *Metridium marginatum,* which makes an interesting inmate of the marine aquarium. Consult Agassiz, E. C., and A., 'Seaside Studies in Natural History' (Boston 1871); Arnold, A. F., 'The Sea Beach at Ebb Tide' (New York 1900); Mayer, A. G., 'Sea-Shore Life' (ib. 1905); Lankester, 'Treatise on Zoology,' Pt. II (London 1901); for American species, Parker, 'American Naturalist' (1900).

SEA-BASS, a fish (*Centropristis striatus*) of the family *Serranidæ* (q.v.), also known as the black-fish, etc. It commonly attains the length of about a foot and a weight of two to four pounds, and is readily known by the large mouth with the teeth of moderate and nearly uniform size, the smooth area on top of the head, the rather large very rough ctenoid scales, continuous dorsal fin with a very strong spine and the slightly trilobate tail with a short filamentous tip to the upper angle. The color is mottled blackish with more or less evident parallel pale streaks. The sea-bass is well known along the entire Atlantic Coast of the United States and is very common from Cape Cod to the mouth of Chesapeake Bay. It lives on rocky ledges wherever an abundance of food offers itself, and feeds voraciously upon all sorts of small crustaceans, fishes, squids and other mollusks, etc. The sea-bass is a sluggish bottom-loving fish, but appears to be somewhat migratory. It spawns in June and the eggs are of small size and buoyant. During the summer large numbers of the young collect in the shallow bays, where eel-grass grows in abundance. Owing to its abundance and the readiness and determination with which it takes the hook this is deservedly a favorite with anglers who lack the opportunity or skill to cope with nobler game. The fishing is done with hand-lines in from 5 to 20 fathoms of water, a heavy lead and a stout hook, preferably baited with squid, being required. Where they are plentiful two fish are frequently brought up simultaneously on as many hooks and large strings are taken during a single slack water, which is the time best suited to their capture. For the market large

numbers of sea-bass are taken by lines and in pound nets on the coasts of New Jersey and Massachusetts. The firmness, whiteness and sweetness of its flesh makes this a table favorite, especially for chowder. The sea-bass is readily propagated artificially, but there has been no necessity for entering upon this work on a large scale. The name is also sometimes applied to various other more or less closely related species.

SEA-BEANS, very hard-shelled seeds of tropical plants carried by ocean currents and deposited on beaches, where they take root. Those washed up on the Florida sands take a high polish and are made into jewelry and souvenirs. The polished, marble-like, pale-gray seeds are those of a tall Central American shrub (*Cæsalpinia bonducella*), known in their native country as the nicker or bondue nuts. They are employed for necklaces and by Indian doctors as a tonic and vermifuge. Other common sea-beans are flattened, like lima beans, with a pitted or granular surface, and are of various sizes and hues, ranging through shades of red and brown to black or mottled. These are the fruits of species of *Mucuna* and *Stizolohium,* the former climbing shrubs, the latter annual herbs, widely dispersed through the tropics and very annoying to travelers, as the seed-pods are covered with stinging hairs, easily detached. The Queensland nut, the Kindal-Kindal of Australia, is a nutritious nut, the fruit of a small Australian tree (*Macadamia ternifolia*) and so valuable as a food that no one is allowed to fell the trees. The seed is about the size of a hazelnut, with somewhat the same flavor. It is squarish, jet black, with a polished surface of iron-like hardness. A woody climber (*Entada scandeus*), native to Australia, the West Indies and other tropical countries bears pods two to four feet long and several inches wide. Its seeds, known as liner-beans, from their color, are used for washing the hair and for laundering and the shells are made into receptacles for trinkets.

SEA-BEAR. See Seals and Sealing.

SEA-BLITE. See Goosefoot.

SEA BOUNDARIES. See Boundaries of the United States.

SEA-BREAMS, fishes of the marine family *Sparidæ,* represented in the United States by the sheepshead and its congeners. They are coast-fishes of modern size, distributed throughout the warm and temperate parts of the world and are usually of dark coloration. They are distinguished by the strength and elaboration of their teeth, fitting them for seizing and chewing crustaceans, mussels and shellfish of all sorts. The fish most famous under this name is probably that of the Mediterranean *Chrysophrys aurata,* called gilthead in England, which sometimes reaches a weight of 20 pounds, and was one of the kinds fattened by the Romans of the classic age in fish ponds and regarded as especial delicacies.

SEA BUCKTHORN, or **SALLOW-THORN,** a monotypic genus (*Hippophaë*) of the *Elæagnaceæ,* confined to temperate Europe and the steppes of central Asia, and living near sea-coasts and alpine rivers. The single species, *H. rhamnoides,* is a thorny shrub, sometimes cultivated, especially for hedges near the sea in sandy soil, where it grows luxuriantly. The leaves are linear lanceolate, silvery in color; the inconspicuous diœcious flowers on the female plants are followed by succulent orange-colored, agreeably acid fruits. When the fruit is ripe in the fall the female plants are very beautiful because the berries are very abundant. These are used for making fish-sauces, jellies and condiments.

SEA-COCOANUT. See Palms.

SEA-COOT, a gunners' name for certain dark-colored ducks, especially the American scoter.

SEA-COW, a name often applied generally to sirenians (see Sirenia; Manatee), but especially restricted to the species formerly inhabiting the Pacific Coast of Kamchatka,—Steller's sea-cow (*Rhytina stelleri*), now extinct. Structurally it differs from other sirenians in the total absence of teeth, the masticating surfaces of the jaws being merely horny pads, very dense and hard. The tail was lobed and the fore limbs small truncate paddles. This was a very large animal, attaining a length of 25 feet and being very bulky. It is now entirely extinct and was under the observation of white men for a bare quarter of a century. In 1741 the explorer Bering and the naturalist Steller discovered this great animal about the shores of two small islands, now known as Bering and Copper islands, in the extreme north Pacific Ocean. It is not known to have lived elsewhere and there is no proof that any examples have been seen since that killed in 1768. Steller has preserved an account of their habits and anatomy during the period when he was a shipwrecked resident of that inhospitable region. The animals were at that time very abundant in the shallow waters about the islands, where they fed upon the large seaweeds which grow there so plentifully. They were extremely sluggish and inactive and of an unsuspicious, affectionate disposition. Upon Steller's return to Germany his discovery and suggestion that the flesh of these great seacows be utilized by explorers were published. Russian traders and trappers visited the islands in large numbers and in the short space of time noted exterminated this interesting animal. Consult Nordenskiöld, N. A. E., 'Voyage of the Vega' (English trans. by Alexander Leslie, 2 vols., New York 1881), and Stejneger, L. H., in the *American Naturalist* (Vol. XXI, Salem, Mass., 1887).

SEA-CUCUMBER, a holothuria (q.v.).

SEA-DEVIL, a devil-fish (q.v.).

SEA-DOVE, the little auk. See Dovekie.

SEA-EAGLE, an eagle of the genus *Haliaëtus,* especially the white-tailed eagle or Erne (*H. albicilla*) of Europe. See Eagle.

SEA-EGG. See Egg-urchin; Sea-urchin.

SEA-ELEPHANT. See Elephant-seal.

SEA-FAN. See Gorgonia.

SEA-FIR, a sertularian. See Cœlenterata.

SEA-FOX, a shark. See Thresher.

SEA-GULL, The (Chalka), a tragedy of Chekhof, first performed in Saint Petersburg in 1896, when the author was 31. It failed, but later met with brilliant success at the Moscow Theatre, and has perhaps been the most popu-

lar of Russian plays on the English stage. It was translated into English by Marian Fell (Mrs. Van Agnew) and published in New York in 1912. A hint at the plot may be given by a sort of algebraic formula: A, a famous actress, is the mistress of B, a famous novelist, who comes with A to visit her brother C, a typical landowner and invalid. A's son, D, who has ambitions as a playwright is in love with E, the beautiful daughter of a wealthy landowner. E, being unhappy at home, has a great desire to go on the stage, and easily falls a victim to B, who seduces her and deserts her, after their child is born. E comes back secretly after two years and has a passionate interview with D, confessing that she still loves B. She disappears, and D shoots himself. On C's estate is a beautiful lake which is the haunt of gulls. D kills one of them and has it stuffed. This «chalka» is typical of the heroine, E. B to E once said: «A young girl grows up on the shores of a lake, as you have. She loves the lake as the gulls do, and is as happy and free as they. But a man sees her who chances to come that way, and he destroys her out of idleness, as this gull here has been destroyed.»

There are passages of wit and humor in the play, but it is chiefly notable for its revelation of the darker strains of human nature, depicted with relentless realism and yet with a passionate sympathy with all suffering, physical, mental and moral. It is also interesting here and there, especially in contrasting the literary methods and aspirations of B and D, giving a hint at Chekhof's own literary creed. And E, the lovely young heroine, shows her whole attitude, in advance of the tragedy which, while it ruins D, only gives the cachet to her own ability as an actress, when she exclaims to her seducer: «For the joy of being an author or an actress I could endure want and disillusionment and the hatred of my friends and the pangs of my own dissatisfaction with myself; but in return I should demand fame — genuine, resounding fame.»

NATHAN HASKELL DOLE.

SEA-HARES, a genus (*Aplysia*), of opistho-branchiate gastropod mollusks, in which the shell is either absent or very rudimentary, and is concealed by the mantle. These animals are slug-like in appearance and derive their popular name from the prominent character of the front pair of tentacles which somewhat resemble the ears of a hare. The side lobes of the mantle are used as fins, and are reflected over the sides and back of the sea-hares, these portions of the mantle thus concealing the shell. This latter structure, when developed, is of oblong, flexible and transparent character. The gills are placed in the centre, and at the posterior portion of the dorsal surface or back; and four tentacles exist. Eyes are present, and are situated at the base of the hinder tentacles.

The sea-hares are widely distributed throughout most seas, and generally inhabit muddy or sandy tracts. The eggs are deposited in long strings. The food consists chiefly of sea-weeds, but they also devour small crustaceans, mollusks and annelids. The mouth possesses thick muscular lips, and the stomach is of compound nature, consisting of a crop, muscular gizzard and accessory cavities. The sea-hares were notorious among the ancients for their supposed venomous properties, and formed ingredients in the poisonous compounds used of old to destroy enemies. Locusta is thus said to have used them against the enemies of Nero; and they formed ingredients in the draught prepared for the tyrant himself. Domitian was similarly suspected of administering the poisonous Aplysiadæ to his brother, Titus. And when Apuleius was accused of practising magic a chief proof against him was the fact that he had employed fishermen to obtain sea-hares for him. These animals, however, are harmless so far as poisonous properties are concerned, except that some species exude an acrid liquor irritating to the human skin. The «lernæa» (*Aplysia leporina*) of the Bay of Naples has an evil reputation among fishermen for causing pain and sickness when touched. The sea-hares also emit a fluid of a rich purple hue, which, like the ink of the cuttle-fishes, has the property of diffusing itself quickly throughout the surrounding water. Gosse mentions that a West Indian species of Aplysia, on being put into a basin of clear sea-water, emitted sufficient of this purple secretion to tinge deeply the whole of the water within a few minutes. Consult 'Cambridge Natural History' (Vol. III, New York 1895); Lankester, 'Treatise on Zoology' (Vol. V, London 1906); Parker and Haswell, 'Text-book of Zoology' (Vol. I, New York 1910).

SEA-HORSE, a small fish of the genus *Hippocampus,* in which the head bears a close resemblance to that of the knight in chess. They belong to the order *Lophobranchii* and the same family (*Syngnathidæ*) as the pipe-fishes. From the latter, and indeed from all other fishes, they differ in having a prehensile tail, which is long, tapering and quadrate in section, owing to the integument of angulated, bony plates, and lacks altogether the caudal fin. The body is compressed, curiously prominent below, protected by rings of spinous bony plates, and bears small pectoral, dorsal and anal fins. In addition to its form the head is remarkable in being supported at right angles to the body-axis on a neck-like construction. Like other parts it is protected by tuberculated or spiny bony plates. A prolonged snout bears the small toothless mouth at its end. The gills are tufted and their arches and covers poorly developed. About half a dozen closely similar species are found in our waters, the best known of which is *H. hudsonicus* found in shallow bays and estuaries along the Atlantic Coast as far north as Cape Cod. There is no more interesting inmate of the marine aquarium than the sea-horse, which twists its tail about the stems of sea-plants, among which it seeks concealment or swims slowly in a very unfishlike attitude, with coiled tail, upright in the water. As in the pipe-fishes the eggs are protected until hatched in a brood-pouch at the base of the tail of the male. Other species occur in the warm waters of the Gulf of Mexico and California. A remarkable related genus is *Phylloperyx* of Australian seas, which bears numerous long cutaneous streamers closely mimicking the seaweeds among which the animal dwells.

In symbolic and heraldic art a «sea-horse» appears as a fabulous marine animal with foreparts like those of a horse, and with hinder

parts like a fish. Neptune is depicted as using them to draw his chariot. In the sea-horse of heraldry a scalloped fin runs down the back. In Biblical literature and early books generally the term often refers uncertainly to the walrus or to the hippopotamus. Consult Gunther, Albert, 'Introduction to the Study of Fishes' (London 1880), and Jordan, D. S., 'Fishes' (New York 1907).

SEA ISLAND COTTON. See COTTON CULTIVATION IN THE UNITED STATES.

SEA ISLANDS, the islands off the coast of South Carolina, south of Winyah Bay. They are a chain of low, flat islands noted for their fertility. The principal islands are Hilton Head, Port Royal, Saint Helena, Edisto, Johns and James. The quality of the long fibred "Sea Island cotton" is famous, and the rice product is large. In 1893 and in 1894 hurricanes devastated several of the islands, inundating them with the tidal waves and destroying the crops.

SEA-KALE, a cruciferous, large-leaved perennial (*Crambe maritima*) indigenous to the coasts of Europe. It has glaucous cabbage-like foliage and clusters of showy white flowers and is cultivated in rich soil for the young shoots and unfolded leaves, which are blanched and eaten as spring vegetables, like asparagus.

SEA-LAMPREY. See LAMPREY.

SEA LAVENDER, SEA PINK, THRIFT, a name common to various species of *Statice* (q.v.), and to the closely allied species of *Limonium.* Several of the former, being hardy, are popularly cultivated as border plants. They include annuals, biennials and perennials with abundant small blue, lilac, yellow or white flowers which are often used for "everlasting" bouquets. Species of *Limonium* are mostly perennial, are useful for cut flowers and for planting among rocks.

SEA-LEMON, a shell-less mollusk of the nudibranch family *Doridæ,* of cosmopolitan range. The body somewhat resembles a lemon in color, showing a beautiful plume-like tuft of gills (when expanded) on the back. These mollusks are carnivorous, feeding on zoophytes, crustacea, etc., and live under stones on the beach, usually near low-water mark. The eggs are emitted embedded in broad gelatinous ribbon-like masses, which may be found attached to the fronds of sea-weeds. These "spawn-coils," as they are named, include immense numbers of eggs. Darwin estimated that upward of 600,000 ova were contained in a coil found at the Falkland Islands.

SEA-LETTUCE, the delicate, thin, waving fronds of *Ulva lactuca,* a pale green sea-weed often used for food.

SEA-LILY, a crinoid (q.v.), especially a living example, as *Pentacrinus;* fossil crinoids are often called stone-lilies.

SEA-LION. See SEALS AND SEALING.

SEA-MAT, or **HORN-WRACK,** a colony of polyzoans (see POLYZOA); specifically, on British shores. Some species of *Flustra,* as the broad horn-wrath (*F. foliacea*).

SEA-MINK, one of the names of the king-fish (*Menticrrhus americanus*). See KING-FISH.

SEA-MOUSE, a free-moving marine annelid of the genus *Aphroditæ,* the most highly organized of "the world of worms." The body is oval, the head is provided with tentacles and two eyes and the back is covered with scales, which, by their expansion and contraction, provide for the admission and expulsion of water from the gills or branchiæ, situated beneath them. The most notable feature of these animals, however, is the beautiful iridescent hues exhibited by the hairs, which, as in other *Errantia,* fringe the sides of the body. The setæ of *Aphroditæ,* even preserved in spirits of wine, still give up these brilliant hues. These animals inhabit deep water and may be obtained by dredging, although they are frequently cast up on shores after storms. Various genera and species exist, some of which are North American. Consult Verill, 'Zoology of Vineyard Sound' (1875).

SEA-ONION, a squills. See SCILLA.

SEA-OTTER, a fur-bearing animal (*Enhydris* or *Latax lutris*) of the weasel family (*Mustelidæ*), and in its webbed hind feet and aquatic habits resembling the true otter, with which it is united zoologically in the subfamily *Lutrinæ.* The sea-otter is of a robust build, about four feet long, with a short blunt tail, short limbs, small fore feet and large, fully-webbed hind feet. The ears are small and the broad muzzle bears spreading tufts of stout bristles. There are but two incisor teeth on each side of the lower jaw and the molar and premolar teeth are remarkable for their massiveness and the bluntness of the cusps. The inner fur, which is very soft, dense and woolly, is deep brown or, in old animals, black, the longer white-tipped hairs being scanty on the body, to which they impart a hoary aspect, but more abundant on the yellowish or grayish head and neck. Sea-otters were formerly very abundant on rocky shores and islands of the north Pacific on both the American and Asiatic sides. The natives of the Aleutian Islands clothed themselves in their skins, but with the increased demand for the fur in China, Europe and America, and especially among the Russian nobility, their unremitting pursuit by native and white hunters has rendered them one of the rarest and most valued of fur-bearing animals. In greatly reduced numbers they are still found in Alaska and within the United States on a very limited reach of the Oregon coast. The otters are now found especially on the island-like masses of the giant bladder kelp or sea-weed and much persecution has made them exceedingly shy and wary. They are strictly marine and never leave the vicinity of water. Their food consists of various kinds of crustacea, mollusks and sea-urchins, which are easily crushed between the blunt massive teeth which are not at all adapted to a fish diet. A single young is born at a time and at any season, and is nursed by the mother as she lies on her back in the water. A century ago a single trading company secured as many as 15,000 skins, valued at $1,000,000, in one year, but now the annual production of all the hunters would not exceed 5,000, and single skins are worth $150 to the hunter and $1,000 or more at the final market. Formerly they were taken in nets, or shot, speared and clubbed; but now are usually shot with rifles either by the natives from boats or while patroling the beach, or from observation tripods erected by white hunters

on the shores. The Alaskan fishery is now regulated by law. Consult Elliot, H. W., 'Report on Alaska' (Washington 1875); Coues, E., 'Fur-bearing Animals' (Washington 1877); Taylor, W. P., 'Osteology and Evolution of the Sea-Otter' (in 'University of California Publications,' Vol. VII, No. 25, Berkeley 1914).

SEA-PEN, an alcyonarian coral of the family *Pennatulidæ* (class *Actinozoa*). It is a compound organism, which consists of a main stem with lateral pinnæ or branches, forming a feather-shaped community. The lower end of the stem is fleshy, destitute of polyps and contains an internal coral-rod, by which the sea-pens attach themselves loosely to the mud of the sea-bed. In color they are reddish-purple, the lower extremity being of a bright orange hue. The branches are studded on their upper margins with the individual polyp, which are connected together through the fleshy medium or cœnosarc. These organisms are common in all the warm seas. The Arctic species, *Umbellularia grœnlandica,* attains sometimes the extreme length of four feet.

SEA PLANES. See Aeronautics.

SEA-RAVEN, a large and very spiny and irregular sculpin (*Hemitripterus americanus*), common about rocky shores and reefs from the Arctic to Cape Cod. See Sculpin; Sea-robin.

SEA-ROBIN, a popular name for certain of the gurnards (*Triglidæ*) in allusion to their generally reddish color and large wing-like pectoral fins. They have rather large heads, encased in bony plates and with flattened snouts and elongated tapering bodies covered with small scales. The pectoral fins are very large and spreading and are especially remarkable in having the three lowermost rays separated from the fin-web and free from one another; they are somewhat enlarged, provided at the end with special organs of touch and are used much like so many fingers to feel the bottom, turn over stones and other small objects and to detect the presence of food. Numerous species of the genus *Prionotus* inhabit American seas, especially southward, the best known of which are the short-winged sea-robin (*P. carolinensis*), with the pectoral fins red and less than half as long as the body and the long-winged sea-robin (*P. strigatus*) with the pectorals brown and more than half as long as the body. Both are common as far north as Cape Cod and the former in Massachusetts Bay also. The sea-robins are extremely interesting to watch, as they turn over small objects on the bottom with their tactile rays in search of the small fishes and crustaceans upon which they feed. Large numbers are caught upon lines and in nets, but though the flesh is white and very excellent, they are not considered to be a food-fish. Several related species are found on the Pacific Coast, and elsewhere, and some are called flying-fish. See Sculpin.

SEA-SERPENT, a more or less mythical sea-monster of serpentine form and reputed gigantic size, whose appearance has been reported at varying intervals and in many seas from the earliest times. The existence of a definite species of serpent of this sort is firmly believed in by most sea-faring men, many of whom have observed conformatory appearances. In a large number of instances these have been quite satisfactorily explained as tide-rows of sea-weed, etc., moved in an undulating fashion by wave action; as schools of porpoises moving in a single file, as giant squids swimming at the surface with their serpentine arms trailing behind, or in a variety of similar ways. There remain, however, a number of accounts whose circumstantiality and general agreement, together with the trustworthiness of the narrators, are such that many zoologists are convinced of the existence of such a monster and few are willing to deny it, although, in the absence of direct proof, a scientific skepticism prevails. That large fishes of serpentine form live in the open ocean is well known and these may prove to be the foundation of many of the sea-serpent stories. Among these are the ribbon-fishes (*Regaleidæ*) of which a number of species have been described. They have elongated, compressed, tapering bodies with oblong heads and toothless jaws and a continuous dorsal fin for the entire length, rising on the head into a prominent crest. Specimens of these fishes exceeding 20 feet in length have been actually washed ashore and examined by naturalists, and others of much larger size have been observed swimming swiftly at the surface, presenting a veritable sea-serpent aspect. One has been taken in the Bermudas, another on the coast of California and perhaps a score on other shores, while many more have been seen alive. The ribbon-fish is supposed to live in the depths of the sea and to come to the surface only occasionally. A slender eel-like shark (*Clamydoselache*) also lives in the deep waters of the Pacific, and if it attains a large size might justify reports of sea-serpents seen in that region. In past ages huge serpent-like creatures did actually roam the high seas, and some naturalists have considered the possibility of some of these persisting in the oceanic abysses down to the present times. The most important of these were the mosasaurs (*Pythonomorpha*), rather closely related to true serpents. During the Cretaceous period they were widely distributed and some reached a length of 60 or 70 feet and were extremely elongated and slender, with pointed heads and two pairs of paddle-like limbs.

The only true marine serpents of the present day are the sea-snakes (*Hydrophidæ*), which live in warm seas of most parts of the world, often far from land. All are of small size, with compressed tails, and are very venomous. They feed on fish, are viviparous and produce their young among the rocky shores of islands, etc.

Consult Goode and Bean, 'Oceanic Ichthyology' (Washington 1875); Gunther, 'Challenger Reports' (Vol. XXII, London 1887); Boulenger, 'Natural Science' (1892); Lee, 'Sea Monsters Unmasked' (London 1883); Oudemans, A. C., 'The Great Sea Serpent: An Historical and Critical Treatise' (London 1893); Wilson, A., 'Leisure-Time Studies' (ib. 1878).

SEA-SIDE GRAPE, a small tree (*Coccoloba uvifera*) of the family *Polygonaceæ*, which grows on the sea-coasts of Florida and the West Indies. It has clusters of edible fruit somewhat resembling currants, and a beautiful hard, violet-colored wood, which produces a red dye and a juice known as West Indian kino, that is nearly as valuable as the officinal kino.

SEA-SLUG, a nudibranchiate mollusk. See NUDIBRANCHIATA.

SEA-SNAKE, a venomous, marine East Indian serpent of the numerous family *Hydrophidæ*. See SEA-SERPENT.

SEA-SPIDER, a spider-like «no-body crab» of the class *Pantopoda;* also, a spider-crab (q.v.).

SEA-SQUIRT, an ascidian or tunicate (qq.v.), so named from the habit of emitting jets of water from the orifices of the body when touched or irritated in any way. Other less apt names found in British books are sea-pear, sea-pork, etc.

SEA-SWALLOW. See TERN.

SEA-TROUT, a popular name for various fishes, primarily for the common salmon-trout (*S. trutta*) of British waters. In other parts of the world various fishes more or less resembling it are called sea-trout, as the weakfish (q.v.) in the southern United States.

SEA-URCHIN, an echinoderm of the class *Echinoidea* (q.v.), members of which differ from crinoids or starfishes in their compact spheroid, discoid or heart-shaped forms without arms or a stalk. The numerous species differ greatly in the number and arrangement of the calcareous plates forming the continuous test and in the character of the spines and other appendages with which the latter is studded. Of both fossil and living forms about 250 genera and 4,000 species are known. Although representatives of the 400 or so living species occur in most seas they are more numerous in warm waters, the West Indian fauna being the richest in the world. Regular sea-urchins are distributed widely in the littoral zone, but the irregular ones are especially characteristic of deep waters and the southern oceans, some of them extending to the utmost abysses. The shallow-water forms being subjected to the constant beating of the surf along the rocky shores which they chiefly inhabit are provided with a highly developed system of suctorial ambulacral feet, by means of which they are enabled to retain a hold. Many species also possess the remarkable power of boring into solid rock in which they excavate chambers exactly fitting them and increasing in size with their growth. Frequently the orifice representing the earlier dimensions of the chamber is too small to permit the urchin's escape and the animal is at once imprisoned in its cave and protected from any possibility of injury by the beating waves. The long-spined *Diadema* thus completely honeycombs the surface of the coral rock of the Bahama Islands, etc. Although this power of excavation is most displayed on soft calcareous rocks, the fact that solid granite is similarly bored in some parts of the world shows that it is not the result of a solvent action, but of a slow wearing away of the rock by the jaws and constant movements of the spines. Sea-urchins of most species swallow rock débris and sand in large quantities, digesting the abundant minute animal and plant life which it contains. Most of the species are gregarious, vast numbers collecting in certain areas on the sea-floor until their bodies completely pave the bottom. During the reproductive season, usually the summer, the ovaries and testes, found in separate individuals, become so greatly enlarged that they fill almost the entire interior of the test. Such forms are called sea-eggs, and this name is sometimes applied to regular sea-urchins generally. In some countries they are baked and eaten while in this condition. The egg-urchin (*Hipponoë esculenta*) of the West Indies is a large species so utilized. But very few species of sea-urchins are found in the shallow waters of the Atlantic Coast of the United States. The green sea-urchin (*Strongylocentratus drobachiensis*) is very common on the rocky shores of New England and the Pacific States. Besides the diatoms, etc., which it digests from the sand that it swallows, it also devours dead animals of every kind. Another example of the regular urchins is the purple or deep brown *Arbacia punctulata,* which is provided with very stout spines and is found from Cape Cod to the Gulf of Mexico. The species of *Diadema* and *Toxopneustes* occur only in the South Atlantic States. Of the flat or cake urchins (*Clypeasteroidea*) the sand dollars (*Echinarachinus parma* and *Mellita testudinata*) are examples. Both live in great numbers buried in the sand or lying on its surface on shoals, the first being most plentiful northward, the last southward. The heart urchin (*Moira atropos*) is the only example of the *Spatangoidea* that reaches even as far north as North Carolina in shallow water. Many interesting species of this and the other groups have been dredged in the deep water along the continental slopes and elsewhere. See ECHINODERMATA; ECHINOIDEA.

Consult Agassiz, 'Revision of the Echini' and subsequent articles in the Memoirs of the Museum of Comparative Zoology (Cambridge 1872); Agassiz, 'Seaside Studies' (Boston 1871); Lang, 'Lehrbuch der vergleichenden Anatomie' (Jena 1894).

SEA-WHIP. See GORGONIA.

SEABOARD AIR LINE RAILWAY COMPANY, the corporate name of a transportation system of southeastern United States. Its main arteries extend from Norfolk and Richmond, Va., southward to Tampa and Miami, Fla., and southwestward to Bessemer and Montgomery, Ala. Under a consolidation agreement of 11 Oct. 1915 the Seaboard Air Line Railway was consolidated on 16 Nov. 1915 under the laws of Virginia, North Carolina and South Carolina with the Carolina, Atlantic and Western Railway under the corporate name of the Seaboard Air Line Railway Company. The Carolina, Atlantic and Western Railway was a consolidation (April 1914) of the North and South Carolina Railway, the Charleston Northern Railway, the South Carolina Western Railway and the South Carolina Western Extension Railway, and had a total mileage owned of 330 miles and 86 miles under construction. Its lines extended from Hamlet, N. C., via Andrews, S. C., to Charleston, S. C., also from Lanes, via Andrews, to the port of Georgetown, S. C., also from McBee, S. C., through Hartsville, Darlington and Florence to a connection with the first-mentioned line at Poston, S. C., with branches to Sumter and Timmonsville. The 86 miles under construction were from Charleston to Savannah, which was opened to freight operation on 15 Oct. 1917 and to passenger operation on 5 Nov. 1917. The former Seaboard Air Line Railway was incorporated

April 10, 1900 in Virginia as successor to the Richmond, Petersburg and Carolina Railroad, a 102-mile road between Richmond, Va., and Norlina, N. C. The Georgia and Alabama Railway was acquired by purchase Feb. 20, 1902; other roads were absorbed in November 1901, and the Florida Central and Peninsular Railroad on June 27, 1903, the system comprising lines extending from Richmond, Va., to Atlanta, Ga., and Jacksonville and Tampa, Fla., with numerous branches, embracing in all over 3,120 miles of road. In November 1909 the Atlanta and Birmingham Air Line Railway, 237 miles; the Florida West Shore Railway, 19 miles, and the Tallahassee, Perry and Southeastern Railway, 39 miles, were merged in the Seaboard Air Line Railway. Its total mileage at present is 4,490.38 miles. The property of the Atlantic, Suwanee River and Gulf Railroad Company, the mileage of which had previously been included in that of the Seaboard Air Line, was transferred during the fiscal year 1909–1910. In 1911–1912 the Seaboard Line absorbed the properties of the Seaboard and Roanoke Railroad and the Roanoke and Tar River Railroad. The Georgia and Alabama Terminal Company is practically merged with the Seaboard, although its corporate existence is maintained. In April 1917 the Seaboard Company took over control of the Tampa and Gulf Coast Railroad and the East and West Coast Railway, and in 1926 it acquired the entire capital stock of the Tavares and Gulf Railway. Through the Seaboard-All Florida Railway, organized in 1925 to lease the Florida Western and Northern Railway Co., and the East and West Coast Railway, the company extended its lines to Miami, Florida, and built new lines, totaling 194 miles, on both coasts of the State. In July 1927 it acquired the entire capital stock of the Jacksonville, Gainesville & Gulf Railway; in Jan. 1928 the common stock of the Georgia, Florida & Alabama Railroad Company; and on Mar. 1, 1928 it acquired the entire capital stock of the Charlotte Harbor & Northern Railroad Company. It owns the entire capital stock of the Baltimore Steam Packet Company, and has an interest in the Macon, Dublin & Savannah Railroad. On Dec. 23, 1930 it was again placed in receivership. Operating revenues in 1929 amounted to $58,151,908, and in 1939 to $44,163,420. It maintains through car service between New York, Philadelphia, Washington, and the South.

SEABORG, Glenn Theodore, American nuclear physicist: b. Ishpeming, Mich., April 19, 1912. A graduate of the University of California (A.B. 1934, Ph.D. 1937), he remained at the university as research associate in the chemistry department. Promoted instructor (1939), then assistant professor (1941), he was appointed professor in 1945. During 1942–1946 he was on leave of absence working in the Metallurgical Laboratory of the University of Chicago. In 1940 he was codiscoverer of element 94 (plutonium), in 1941 of nuclear energy isotope Pu-239, and in 1944 of elements 95 (americium) and 96 (curium, qq.v.). In 1946 he became a member of the general advisory committee of the Atomic Energy Commission.

SEABURY, sē′bŭ-rĭ, **Samuel,** American Protestant Episcopal bishop: b. North Groton, Conn., Nov. 30, 1729; d. New London, Conn., Feb. 25, 1796. He was graduated at Yale College in 1748, and three years later took a course in medicine at the University of Edinburgh. He did not, however, practice this profession, but entered at once upon a course of theological study. He was ordained deacon and priest in the English Church in London in December 1753. Returning to America in the following summer, he became rector of Christ Church, New Brunswick, N. J. In 1757 he took charge of Grace Church, Jamaica, L. I., and in 1766 of Saint Peter's, Westchester, N. Y. In the autumn of 1775 he was obliged on account of his Loyalist sympathies to leave his parish and he resided, during the greater part of the war, in New York. He wrote numerous articles in support of the Tory cause, of which he was one of the ablest advocates, and suffered much, even to imprisonment and exile, for his loyalty to the king, though when peace was declared no one was more faithful to the United States. Immediately after the articles of peace were received in New York, 10 out of the 14 Episcopal clergymen in Connecticut assembled at Woodbury to consider action as to the organization of the Church under the changed civic conditions. On the first formal ballot, they elected Dr. Seabury as bishop. He then sailed for England, and waited in London more than a year for consecration by the English bishops. Owing to the connection between the Church of England and the state, various political reasons stood in the way, and he finally determined, in pursuance of his original instructions, to apply to the Scottish bishops, who were in a more independent position. On Nov. 14, 1784, Seabury was accordingly consecrated at Aberdeen by the bishop and coadjutor-bishop of that see and the bishop of Moray and Ross. He then returned to America and there, in addition to his episcopal duties, assumed the rectorship of Saint James' Church, New London, which he held until his death. His jurisdiction was recognized over Rhode Island as well as Connecticut and afterward over Massachusetts; but the validity of his consecration was denied by many, partly owing to the prejudice excited by his former political attitude. In 1789, however, it was expressly affirmed by the General Convention. Seabury exercised much influence on the final shape of the constitution and liturgy of his Church, especially (in accordance with his agreement with the Scottish bishops) by insisting on the restoration of the oblation of the elements and invocation of the Holy Ghost in the Eucharistic office. He was a man of pronounced views, but of great simplicity, humility and self-sacrifice; and the value of his services to the infant Church can scarcely be overestimated. Consult Beardsley, E. E., *Life and Correspondence of The Rt. Rev. Samuel Seabury* (1881); Tyler, M. C., *Literary History of the American Revolution* (1897).

See also Protestant Episcopal Church.

SEABURY, Samuel, American Protestant Episcopal clergyman, grandson of Bishop Samuel Seabury (q.v.): b. New London, Conn., June 9, 1801; d. New York, Oct. 10, 1872. He was privately educated but took his A.M. at Columbia College in 1823. He was ordained in 1828, was professor of languages at Flushing Institute and Saint Paul's College in 1828–1834 and in 1834–1849 he edited the *Churchman.* He was rector of the church of the Annuncia-

tion, New York, in 1838–1868, and from 1862 he was professor of Biblical learning at the General Theological Seminary, New York. Among his books are *The Continuity of the Church of England in the Sixteenth Century* (1853); *American Slavery Distinguished from the Slavery of English Theorists and Justified by Law of Nature* (1861); *Theory and Use of the Church Calendar* (1872).

SEABURY, Samuel, American lawyer and judge: b. New York, N. Y., Feb. 22, 1873. The son of the Rev. William Jones Seabury and a great great grandson of Samuel Seabury (qq.v.), first bishop of the Protestant Episcopal Church in America, he was educated by his father and in New York private day schools. The New York Law School conferred on him the LL.B. degree in 1893; he continued his studies during a postgraduate year and was admitted to the bar in 1894. Elected justice of the City Court of New York in 1901, he was in 1906 elected a justice of his state's Supreme Court for a 14-year term, but resigned in 1914 when elected associate justice of the Court of Appeals, New York State. He resigned his justiceship in August 1916 and the next month was nominated by the Democratic Party as its candidate for the governorship, but lost the election to Charles S. Whitman, re-elected governor for a second term. In 1930 he was appointed referee of the Appellate Division, 1st Judicial Department, New York, to investigate conditions in the magistrate courts, and the following year Gov. F. D. Roosevelt appointed him to hear charges filed against the district attorney of New York County. The same year he was counsel of the Joint Legislative Committee to investigate the affairs of New York City. His investigations revealed widespread corruption in the city government. Mayor James J. Walker, deeply involved, was forced to resign. Judge Seabury earned a national reputation as a foe of boss rule and champion of honest city administration.

SEABURY, William Jones, American Episcopal clergyman: b. New York, Jan. 25, 1837; d. Aug. 30, 1916. He was graduated at Columbia University in 1856 and received his master's degree there three years later. He took the degree of doctor of divinity at Hobart College in 1874, receiving the same degree from the General Theological Seminary in 1885. Meantime he studied law in the office of the late Stephen P. Nash, was admitted to the bar in 1858 and for a short time engaged in practice. Wm. Seabury succeeded his father in 1868 as rector of the Church of the Annunciation, where he remained until 1898. He was appointed to the chair of ecclesiastical polity and law in the General Theological Seminary in 1873 and occupied it until his death. During the latter part of his tenure he was the senior professor in the service.

SEACOAST ARTILLERY. See ARTILLERY.

SEAGER, Henry Rogers, American economist: b. Lansing, Mich., July 21, 1870; d. Kiev, Russia, Aug. 23, 1930. He was educated at the universities of Michigan, Pennsylvania, and Johns Hopkins, and then did further postgraduate work at Berlin, Halle, and Vienna. He was professor of political economy at the University of Pennsylvania in 1897–1902; was connected with the faculty of Columbia University from 1902, and from 1905 was professor of political economy there. In 1917 he was appointed secretary of the Shipbuilding Labor Adjustment Board at Washington, D.C. Author of *Introduction to Economics* (1904); *Economics Briefer Course* (1909); *Social Insurance* (1910); *Principles of Economics* (1917); *Practical Problems in Economics* (1923), etc.

SEAL, an engraved stamp bearing a device or inscription pertaining to the owner; also, the impression of such a stamp on a plastic substance, such as wax. A seal upon a document was originally a substitute for a signature; a seal upon a place of deposit was for security. Seals were used in pre-Christian times, and one of the earliest and commonest forms was the signet ring. In Egypt impressions of seals were made in fine clay, and attached to documents by slips of papyrus. The Romans used clay, beeswax and, in the time of the empire, lead for taking impressions. The Normans reintroduced beeswax in the Middle Ages; sealing wax was invented in the 17th century. Documents in England are still sealed as a formality, but the true voucher, to which alone any real importance attaches, is the signature.

There are three seals officially used in England by or in name of the sovereign—the great seal, the privy seal and the signet. In the United States, on July 4, 1776, Congress appointed Benjamin Franklin, John Adams and Thomas Jefferson a committee to prepare a device for the great seal of the United States. The committee reported various devices. William Barton, of Philadelphia, was appointed to submit designs. Sir John Prestwich, an English antiquarian, suggested a design to John Adams in 1779. Combining the various designs of Barton and Prestwich, a seal was adopted, June 20, 1782, as follows: Arms: Paleways of 13 pieces argent and gules; a chief azure; the escutcheon on the breast of the American eagle displayed proper, holding in his dexter talon an olive branch and in his sinister a bundle of 13 arrows, and in his beak a scroll with the motto: *E Pluribus Unum;* Crest: a glory breaking through a cloud proper and surrounding 13 stars; Reverse: A pyramid unfinished. In the zenith an eye in a triangle, surrounded with a glory proper, over the eye the words, *Annuit Caeptis.* Beneath the pyramid, MDCCLXXVI and words, *Novus Ordo Sacculorum.* The Confederate seal adopted by the Confederate Congress, April 30, 1863, was designed by Thomas J. Semmes, of Louisiana. The device represents an equestrian portrait of Washington, surrounded by the principal agricultural products of the Confederacy.

SEAL ISLANDS. See LOBOS.

SEAL OF THE CONFEDERACY. See GREAT SEAL OF THE CONFEDERACY.

SEAL OF THE UNITED STATES, Great. See GREAT SEAL OF THE UNITED STATES.

SEALING WAX, a resinous preparation used for securing folded papers and envelopes, and for receiving impressions of seals set to instruments. Ordinary red sealing wax is made

of pure bleached lac, to which when melted are added Venice turpentine and vermilion. Inferior qualities consist of common resin and red-lead, and black and other colors are produced by substituting appropriate pigments. Sealing wax was invented in the 17th century. Its use for sealing letters has been generally given up in favor of mucilage which, when moistened, fastens envelopes much more effectively and with greater rapidity than sealing wax.

SEALS AND SEALING. There are world-wide fisheries devoted primarily to the capture and utilization of fur seals and hair seals. Of less importance to these fisheries, but nevertheless objects of the hunt when sufficiently abundant, have been the sea lions, sea elephants, walruses and other marine mammals. The high value of the fur, leather, and oil products of this fishery in world commerce has brought many species perilously close to extinction while others, protected by international agreements and restrictive regulations, continue in abundance.

These animals all belong to the order *Pinnipedia* and are classified in three families: (1) *Otariidae,* the eared seals (fur seals), and sea lions; (2) *Phocidae,* the true seals or hair seals and sea elephants or elephant seals; and (3) *Odobenidae,* walruses. All are related to but differ from the carnivores in the finlike structure of the feet. Of the three families, the hair seals are the most highly specialized for aquatic life. The neck is short and the head can be raised only slightly; there are no external ears; and the posterior limbs are adapted for swimming to such an extent that these animals move with difficulty on land, whereas fur seals, sea lions and walruses can move with great rapidity in an undulating lope.

Fur Seals.—The fur seals of the world belong to two distinct groups or genera. One of these, the genus *Arctocephalus,* is widely distributed throughout the Southern Hemisphere where its members formerly existed in vast numbers along portions of the coasts of South America, South Africa, Australia, and New Zealand, as well as on many of the islands and land masses of the Antarctic regions. Only one species of this genus, the Guadalupe fur seal, occurs north of the equator. It was once abundant on the islands off the coast of southern and Lower California but only a few animals still remain. The second group of fur seals belong to the genus *Callorhinus* and are confined to the North Pacific; there are no fur seals in the North Atlantic.

By far the largest and most important herd of fur seals in the world is the Alaska herd which has its breeding grounds on the Pribilof Islands in Bering Sea. Here more than 80 per cent of all the fur seals in the world gather every year for four to six months, take up their only terrestrial life, give birth to their young, breed, and yield a part of their number to satisfy the couturiers of fine furs. Other herds of commercial importance resort to the Commander Islands off the Siberian coast, controlled by Russia; Robben Island and the Kuriles, formerly belonging to Japan, but now administered by Russia; Lobos Island belonging to Uruguay; and to the coastal area and adjacent islands in the vicinity of the Cape of Good Hope, South Africa. Remnants of once large herds are still to be found on many of the small islands in the South Atlantic, the Crozet Isles in the South Indian Ocean, and on Guadalupe and the Galapagos Islands in the Pacific. Tasmania, New Zealand, and Australia still have small colonies but these have been so reduced in size that the number of skins now obtained is insignificant.

Each herd is an independent, self-perpetuating unit, and the animals of the various herds do not intermingle. Permanent, constant anatomical differences between the animals of the several herds, both in the genus *Arctocephalus* and in the genus *Callorhinus,* have resulted in classification of their members as distinct and separate species. At least six species of the genus *Arctocephalus* and three of the genus *Callorhinus* have been described.

Southern Hemisphere.—Fur seals of the Southern Hemisphere were the first to feel the impact of commercial operations. Toward the end of the 18th century fur seal hunting began and grew rapidly in importance, and early in the 19th century it assumed gigantic proportions. Sealing first began at the Falkland Islands about 1784, and, according to the old accounts, "millions were taken during the next fifteen years." Fur seals were present in such numbers that there are records of "eight or nine hundred in a day" being killed with clubs on a single small islet. There are no fur seals on the Falkland Islands today and it is presumed they became extinct about 1800. Sealing voyages were made to the west coast of South Africa as early as 1790. The sealing fleet extended its range to include first the South Georgian rookeries, then successively those off the coast of Chile, Patagonia, Australia, the Antipodes, Crozet and Prince Edward Islands, the South Shetlands, Kerguelen Island, and others of lesser importance. There were approximately 60 vessels in the sealing fleet in 1801. The United States, Great Britain, Portugal, Germany, Russia, and France were represented in this enterprise. The fur seal skins obtained were taken mostly to the Canton market where, in exchange for teas and silks, they brought the comparatively low price of fifty cents to five dollars each. The sealing business was a profitable one, however, and this stimulated indiscriminate and exterminating slaughter. One after another of the populous seal rookeries was discovered and despoiled. Every seal that could be obtained was killed regardless of sex or age. So vigorously was sealing prosecuted that when the South Shetland rookeries were discovered in 1820 their immense wealth of seal life was nearly exterminated in a single season. There is a record of one vessel taking 57,000 fur seal skins in one season's operations. The period of prosperity was short-lived, and fur seals are now present in the Southern Hemisphere in significant numbers only on the South African coast and on Lobos Island near Maldonado, Uruguay, where they are protected and utilized on a management basis. Fur seals elsewhere south of the equator owe their existence to the inaccessibility of the rocky shores they inhabit, which offer partial protection against human predation.

Northern Hemisphere.—In the North Pacific, the Pribilof Islands were discovered by the Russian navigator, Gerassim Pribilof, in 1786, and the slaughter of the fur seals began there immediately, following the same destructive pattern pursued in the Southern Hemisphere. At the time of discovery, it was estimated that this herd contained at least 5,000,000 fur seals. In

the 50 years immediately following discovery about 2,000,000 fur seals were killed. By 1835 the Russian management had grown apprehensive as to the future of the herd and, in consequence, imposed restrictions on shore killings on the Pribilofs. Fortunately, these restrictions came soon enough and the herd responded to the more favorable conditions. In 1867, when these islands were acquired by the United States in the Alaska purchase, there were 3,000,000 fur seals in the herd.

During the first 40 years of ownership by the United States, the sealing privilege on the Pribilofs was leased to private companies, and more than 2,300,000 fur seal skins were taken, for which about $9,500,000 was paid into the United States Treasury. Such operations on shore were carefully regulated, but in 1879, and thereafter until stopped by the treaty of 1911, pelagic sealing, the killing of seals at sea, took a heavy and damaging toll and the herd suffered a serious decline. The Indians of the northwest coast from time immemorial followed the custom of spearing fur seals from their canoes as the herd passed along their shores from February to May. The number of animals so taken, primarily for food, was small and probably never exceeded a few thousand. In 1879 schooners engaged in this fishery, equipped to transport hunters and canoes to the sealing grounds and to care for them there. These schooners, averaging 70 tons, with sealing canoes and hunters on board, sailed chiefly from Victoria, B. C., but others based at Pacific Coast ports from San Diego to Seattle. Pelagic sealing commenced off the California coast late in December, and the migrating Pribilof herd was followed northward into Bering Sea where operations continued until September. A less important pelagic sealing industry was dependent upon the Japanese and Russian fur seal herds, the sealing grounds extending from the latitude of Yokohama to the Commander Islands in Bering Sea, and the season extending from March to September.

The rise of pelagic sealing was rapid. From one vessel in 1879, the sealing fleet had expanded to 122 vessels by 1891. The pelagic sealing fleet reached its zenith in 1894 when the ocean catch from the Pribilof herd totaled 143,000 animals. Thereafter the pelagic catch declined, and in 1902 was only about 15,000 seals.

Sealing on land could be controlled, for there the animals to be killed could be selected with respect to sex and age. At sea, however, all animals were targets for the guns of the pelagic sealers. The result was the loss of many injured animals, and many that were killed outright sank before they could be reached. In all cases, the killing of female seals at sea meant the destruction of unborn pups or of a pup left on shore to starve. The pelagic sealing catch, therefore, did not reflect accurately the drain on the herd.

Pelagic sealing was an extremely wasteful process but nothing could be done about it because it was carried on in waters beyond the control of the United States government. To be sure, an effort was made to prevent sealing in Bering Sea. Acting upon the precedent established by Russia in the ukase of 1821, the United States seized and confiscated a number of sealing vessels that entered Bering Sea. A lengthy controversy with Great Britain ensued, since the pelagic fleet was very largely of Canadian registry. In 1892 the entire matter was remanded to a tribunal of arbitration for settlement of the question of jurisdiction over fur seals in offshore waters, and also for recommendation of measures for the protection of fur seals. The tribunal of arbitration met in Paris in 1893 and denied the United States authority to exercise jurisdiction over Pribilof Islands' fur seals when such animals were more than three miles from shore. Regulations were formulated, the essential features of which were the establishment of a closed zone of 60 miles in Bering Sea about the islands, and a closed season from May 1 to August 1, within which all pelagic sealing was prohibited. These regulations were inadequate and the Pribilof herd continued to decline.

International Protection.—By 1911, this once great herd numbered only 125,000 animals. Extinction seemed certain. It was averted at the last possible moment, by the action of conservationists of the United States, Great Britain, Japan, and Russia, who finally succeeded in getting their countries to accept the terms of the fur seal treaty of 1911. Under the terms of this convention, the nationals of each of the treaty powers were prohibited from engaging in pelagic sealing in the waters of the North Pacific Ocean north of the 30th parallel of north latitude including the Seas of Bering, Kamchatka, Okhotsk, and Japan. Exception was made for aborigines in treaty waters using primitive methods. Management of fur seals on land was left to the country having jurisdiction over the rookery area, and provision was made for Japan and Canada to each receive 15 per cent of the land killings by the United States and Russia, and for the United States, Russia, and Canada to each receive 10 per cent of the land killings on Japanese seal islands. Great Britain had no shores frequented by fur seals within the protected area. This convention, as drawn, was to remain in effect for 15 years and thereafter until one of the treaty powers should give one year's notice of desire to terminate it. Japan gave notice of abrogation on October 23, 1940 and the treaty was terminated on October 23, 1941.

A provisional fur seal agreement was entered into by the United States and the Dominion of Canada on December 19, 1942, and a new Alaska fur seal law, giving effect to the provisional agreement, was approved on February 26, 1944. With enforcing legislation by the Canadian government, the agreement provides, among other things, for continuation of the prohibition on pelagic sealing, and for delivery to Canada of 20 per cent of the skins taken on the Pribilof Islands, the remainder to be retained by the United States.

The international cooperation afforded by the treaty of 1911 and the provisional agreement of 1942 has resulted in the most outstanding of all accomplishments in the conservation of wild life. Since 1911 the herd has steadily increased until it numbers more than 3,000,000 animals. In this same period about 1,500,000 seals were killed for their fur. This almost phenomenal growth has been possible only through careful management, taking into consideration all phases of the seal's natural history. Were it not for the polygamous nature of fur seals, the birth of both sexes in equal proportions, and the early maturity of the females, the herd would still be of almost insignificant size.

The convention of 1911 during the 30 years it was in effect afforded protection to the Robben

COMPUTATION OF PRIBILOF ISLANDS FUR SEAL HERD AND NUMBER OF SEALSKINS TAKEN BY THE GOVERNMENT, 1910–1949

Year	Sealskins obtained	Animals in herd	Year	Sealskins obtained	Animals in herd
1910	12,964	132,279	1930	42,500	1,045,101
1911	12,138	123,600	1931	49,524	1,127,082
1912	3,191	215,738	1932	49,336	1,219,961
1913	2,406	268,305	1933	54,550	1,318,568
1914	2,735	294,687	1934	53,470	1,430,418
1915	3,947	363,872	1935	57,296	1,550,913
1916	6,468	417,281	1936	52,446	1,689,743
1917	8,170	468,692	1937	55,180	1,839,119
1918	34,890	496,432	1938	58,364	1,872,438
1919	27,821	524,235	1939	60,473	2,020,774
1920	26,648	552,718	1940	65,263	2,185,136
1921	23,681	581,443	1941	95,013	2,338,312
1922	31,156	604,962	1942	150	2,585,397
1923	15,920	653,008	1943	117,164	2,720,780
1924	17,219	697,158	1944	47,652	2,945,663
1925	19,860	723,050	1945	76,964	3,155,268
1926	22,131	761,281	1946	64,523	3,386,008
1927	24,942	808,870	1947	61,447	3,386,008
1928	31,099	871,513	1948	70,142	3,837,131
1929	40,068	971,527	1949	70,891	

Island herd, then under the jurisdiction of Japan, and to the Commander Islands herd belonging to Russia. The Robben Island herd was estimated to contain 40,000 seals and the Commander Islands herd 100,000 when the treaty was terminated.

Natural History.—The hardy old males or bulls are the first to arrive at the Pribilof Islands in the spring, often hauling out on shore before the snow has disappeared. Each selects his summer home at a place along the shore where he may induce the greatest number of females or cows to join him. The younger, less experienced bulls are forced to take up their places at less advantageous points along the shore and consequently they acquire for their harems fewer cows. A family group or harem may comprise as many as 100 cows to one bull. Once a cow has joined the group there can be no amiable separation, and any move toward desertion ends in physical admonition for the wayward wife and scars and bruises for the covetous neighbor who tried to lure her into his harem. Nor are immature animals, except the newborn pups, allowed to intrude where the harems are established. The bulls see to that by keeping a constant vigil, unbroken even to obtain food or sleep.

Each fur seal cow gives birth to one young within a few hours after she lands at the islands. Jet black and weighing about 12 pounds at birth, the pups grow rapidly, and by fall are almost as large as their mothers. Breeding takes place soon after the young are born, the period of gestation, therefore, being approximately one year. The females are mature in their second year and give birth to their first pup when three years old. Males mature when about seven years old. Both males and females have a life span of about 15 years. At maturity a fur seal bull weighs about 500 pounds, and a cow about 90 pounds. Pups and cows leave the Pribilofs in November for the southward migration followed later by the other seals as winter approaches. This migration extends to the latitude of southern California, which is reached in December. The northern movement begins soon after the first of the year and the great majority of the animals arrive at the Pribilofs in July.

Fur seals feed on whatever is readily available. On the northward migration herring is important in their diet but many little known species having no commercial value are eaten also. The principal food throughout their range, and one for which a definite preference seems to exist, is squid. There is no evidence that the growing Pribilof Islands fur seal herd is a menace to any existing commercial fisheries.

Because of the polygamous habits of the fur seal and the fact that the sexes are in equal numbers at birth, there are many males unneeded to maintain the herd and provide for its continued growth. Instead of permitting the normal increase of male animals, therefore, this sex is maintained at the most desirable ratio by killing the surplus males for their fur. The fur is most desirable on the 3-year-olds, and from the males of this age group known as "bachelors," come the fur seal coats of the world. The bachelors very considerately segregate themselves from other seals on shore, and the job of killing the right animals thus is made easy. A proper number of the more fortunate 3-year-old males are reserved from killing to be future harem-masters. No female is ever purposely killed.

To carry on sealing at the Pribilofs in the early days, the Russian operators established colonies of natives from the Aleutian Islands on St. George and St. Paul islands where the principal rookeries exist. The descendants of these people, numbering about 500, still live at the Pribilofs and carry on the sealing operations under the direction and supervision of employees of the United States Fish and Wildlife Service. In return for this work they receive all of the necessities of life, including food, clothing, shelter, school facilities, and medical attention; and, in addition, cash payments are made to them for each skin taken.

Most of the skins are taken in July, and after preliminary preparation at the islands, they are shipped to a government-supervised factory in St. Louis where they are dressed, dyed, machined, and finished for sale at public auction to the highest bidder. The process of preparing fur seal skins for market is a difficult one requiring at least three months for each skin. At the end of the process the leather side of the skin has the same soft feel that one associates with the finest type of chamois, and the soft, lustrous fur has become unequalled for beauty and durability.

Hair Seals.—Hair seals are universal in their distribution but occur in sufficient numbers to support important fisheries in only a relatively few, well defined localities. They include the waters along the west coast of Greenland, the coasts of Newfoundland, Labrador, and the Gulf of St. Lawrence; Jan Mayan Island and adjacent waters; Novaya Zemlya Island and adjacent waters, and the White Sea. The Caspian Sea also supports a hair seal fishery. Small isolated groups of hair seals, of local importance only, are found along both coasts of the United States, around the British Isles, among the islands of the south seas, along both coasts of South America, and in Alaskan and Siberian waters. The species of chief importance commercially are the harp seal (*Phoca groenlandica*), the hood seal (*Cystophora cristata*), the harbor seal (*P. vitulina*), and the Caspian seal (*P. caspica*). The ringed seal (*P. hispida*) and the gray seal (*Halichoerus grypus*) also are taken. The harp seal which gets its name from dark markings on its back which resemble a harp, is, both in number of animals captured and value, the species of greatest commercial importance. In years of normal operation, the number of harps killed has equalled or exceeded the number of all other

species combined. It is the seal on which the Newfoundland, Greenland, and Arctic fisheries depend.

The once extensive hair seal fishery of the South Atlantic, South Pacific and Antarctic regions was primarily for the capture and utilization of the elephant seal or sea elephant, the largest member of the hair seal family. This fishery, prosecuted in conjunction with whaling and fur sealing, was exclusively for the oil. Elephant seals were abundant on many of the islands off the southern coasts of South America, Patagonia, the Falkland Islands, the South Shetlands, the South Georgian Islands, and Crozet and Kerguelen islands. The slaughter of these animals in the early years of sealing was without any thought of the future and the inevitable result has been extermination in many places. This fishery now has been abandoned and where this species has been protected, it is showing rapid recuperation.

The Newfoundland hair seal fishery is the most important in the world. For reasons of economic difficulties besetting the industry as well as decimation of the seal herds, this fishery has shown evidence of failing. In 1855, 400 vessels and 13,000 men were engaged in this fishery and took a total of more than half a million seals. Prior to that time there had been a gradual change in the method of sealing, from exclusively shore operations employing nets, to ice skiffs, small schooners, brigs, brigantines, and barks, successively. After 1855 the decline in sailing vessels commenced, and twenty-five years later they were a thing of the past. Steamers appeared in the fishery in 1863, and by 1906 there were 25 steamers engaged in furnishing employment to more than 4,000 men. The number since then has gradually declined and in 1938 only eight steamers and 1,459 men were engaged in sealing. Several disasters in which two sealing steamers were lost in 1940 and one in 1943, with diversion of others to emergency duties during World War II, brought a further decline to this industry, and in 1946 operations were limited to one steamer and four small motor vessels of less than 200 tons each.

The catch of seals through the years has followed a downward trend paralleling that of ships and men employed. Until about 1860, the average annual take of seals was in excess of 500,000. From 1860 until the early part of the 20th century, the catch averaged well above 200,000 annually, but after World War I dropped to an average of less than 125,000. The catches in 1941, 1942 and 1944 were insignificant; the sealing fleet did not operate in 1943 or 1945. This appears to be the closing chapter of another colorful, highly speculative industry replete with adventure, romance, and tragedy.

The principal species taken in the Newfoundland fishery is the harp seal, though hoods are taken in considerable numbers. These animals follow fairly definite routes of migration. Late in October they leave the Arctic ice and migrate south as far as the great Ocean banks off Cape Race. In this migration the harps appear to originate in the vicinity of Hudson Bay and the hoods come from the Greenland shores, the two species meeting off the Labrador coast. Returning north, they again mount the ice about the end of February in the neighborhood of the Strait of Belle Isle. At this time the young are born, and about a month later the hunt begins. Voyages commence early in March with much pomp and ceremony as the vessels sail from St. John's harbor. They cruise in a northerly direction, usually first locating the seals in the vicinity of Funk Island, between 50 and 100 miles off the northeastern coast of Newfoundland. The seals, congregated in great numbers, are rounded up, cut off from open water, and clubbed over the head. When all the seals are killed, the hunters remove the skins with the adhering layers of blubber and drag them back to the ship to be packed into the hold. When a full cargo is obtained the vessel returns to its home port where the skins are unloaded, the blubber removed, and the hides prepared for manufacture into leather.

Hair seals do not have the fine under-fur that characterizes fur seals, and comparatively little use is made of these skins in clothing. The oil extracted from the blubber is used as a lubricant, in the leather industry, and in soap manufacture.

The hair seal fishery of Jan Mayan Island ranks second to that of Newfoundland and was prosecuted by vessels from England, Norway, and Germany. The catch never equalled that of Newfoundland, and signs of depletion developed early. Despite attempts at regulation, this fishery was seriously depleted by the end of the 19th century. Substantial catches are made annually at Novaya Zemlya, and in the White and Caspian seas. Many hair seals are taken annually along the Alaskan and Siberian coasts of the North Pacific and Arctic oceans by native peoples for food and clothing; no commercial fishery of any consequence is carried on in these waters. Bounties are offered for destruction of the harbor seals in parts of Alaska and in some of the Pacific Coast states where they occur in sufficient numbers to be considered a menace to the various species of food fish of commercial importance.

SETON H. THOMPSON,
Chief, Division of Alaska Fisheries, United States Fish and Wildlife Service.

SEALSFIELD, sēlz'fēld, **Charles,** pseudonym of KARL ANTON POSTL, Austrian novelist: b. Poppitz, Moravia, March 3, 1793; d. Solothurn, Switzerland, May 26, 1864. He early entered a monastery and was ordained in the priesthood, but in 1822 fled to Switzerland and thence to the United States where he lived in 1822–1826 and 1827–1830. In 1829 he edited in New York the *Courier des Etats Unis,* and after 1832 made his residence chiefly in Switzerland, though he visited the United States at intervals. He subsequently engaged in novel writing, his work creating a sensation in Germany. His publications include *Die Vereinigten Staaten von Nordamerika* (1828); *Der Legitime und die Republikaner* (1833); *Lebensbilder aus bei den Hemisphären* (1835–1837); *Das Kajütenbuch* (1840); *Süden und Norden* (1842–1843).

SEALY, city, Texas, in Austin County, 48 miles west of Houston, on the Missouri-Kansas-Texas and the Gulf, Colorado and Santa Fe railroads. It is a trade and market center for cotton and corn. Pop. (1950) 1,942.

SEAMAN, Lazarus, English clergyman: d. probably Sept. 9, 1675. He was born in Leicester early in the 17th century. He was graduated from Cambridge in 1627 and became a teacher, and chaplain to the earl of Northumberland. He became rector of All Hallows, London, in 1642. After 1645 Seaman was engaged in attempts to secure toleration for the Nonconformists, of whom he was one. Their case was presented to Charles I in 1648, and the king complimented Seaman on his ability. During Cromwell's Commonwealth, which followed soon after, Seaman held various offices at Cambridge, but was deprived of them after the restoration of Charles II. The Act of Uniformity and the Five Mile Act (qq.v.) hampered his public work until the Declaration of Indulgence (q.v.).

SEAMAN, Louis Livingston, American surgeon: b. Newburgh, N. Y., Oct. 17, 1851; d. Bronxville, N. Y., Jan. 31, 1932. He was graduated at Cornell University in 1873, at Jefferson Medical College in 1876 and at University Medical College, New York, in 1877. He was resident surgeon in the New York State Emigrant Hospital in 1877–1879; superintendent of the State Emigrant Insane Asylum in 1879–1881 and chief of staff at Blackwell's Island in 1881–1885. He made a tour of the world and special study of the contagious diseases of the Orient in 1886. He was surgeon with rank of major in the American War with Spain; served with the Second Imperial army of Japan in Manchuria in 1905, and was special correspondent of the *Independent* in World War I. His books include *The Real Triumph of Japan* (1906); *Triumphs of Medical Science in Peace and War in Foreign Lands* (1908); *The Tse-Tse Fly and Sleeping Sickness* (1908); *The Aftermath of the Balkan War* (1914).

SEAMAN, sē'man, Sir **Owen,** English writer: b. Sept. 18, 1861; d. London, Feb. 2, 1936. He was educated at Cambridge, in 1888 became lecturer in literature at the Durham College of Science (Newcastle-on-Tyne), and in 1890 was there appointed to the newly-established professorship of literature. In 1897 he was admitted barrister of the Inner Temple. He began contributions in 1894 to the *National Observer,* in 1895 to the *World* and in 1894 to *Punch,* whose staff he joined in 1897, and of which he became editor in 1906. Author of *With Double Pipe* (1888); *Horace at Cambridge* (1894); *Tillers of the Sand* (1895); *The Battle of the Bays* (1896); *In Cap and Bells* (1899); *Borrowed Plumes* (1902); *A Harvest of Chaff* (1904); *Salvage* (1908); *War Time Verses* (1915).

SEAMAN, William, English Orientalist: b. 1606; d. Nov. 7, 1680. He was graduated from Oxford in 1623 or 1624, and from 1628 until his death he was rector of Upton-Scudamore. Shortly after 1628 he went to Constantinople where he entered the service of Sir Peter Wyche, the English ambassador there, who became his patron. During Seaman's stay in the capital, he perfected his knowledge of the Turkish language. This study led him to translate into English a short history of Turkey, published in 1652 after his return to England. At about the same time he was engaged in making a translation of the New Testament into Turkish. This work, the first of its kind, was published in part in 1659 and, in a complete edition, at Oxford in 1666. For the ensuing century and a half Seaman's translation of the Scriptures remained the only one in print. He also wrote a grammar of the Turkish language, published in 1670.

SEAMAN, a person below the rank of officer who is employed in the navigation of a vessel either coastwise or on the high seas. The word "sailor" is broader in meaning than that of seaman, including men employed on inland waters as well as at sea, and in the United States, with a vast area of navigable lakes, sailor is the term more generally used. Seamanship is, of course, as old as navigation, and that originated before the historic period. Although in ancient times vessels were propelled to a great extent by the labor of slaves, chained to the oars they handled, the men engaged in navigating ships were usually free, and the ancient seamen appear to have had more voice in matters affecting the voyage than seamen have today. Commerce by water was the chief source of the wealth which made Tyre and Carthage, and some of the Greek cities in Asia and Europe rich and powerful, and skilful seamen were, therefore, in great demand. Similar conditions prevailed in the more prosperous republics of the Middle Ages and the Northmen who spread their sails in search of lands they could plunder and subdue were sailors and warriors both.

The discovery of America gave a great impulse to seamanship and may be said to have created a new race of sailors, who were also adventurers and whose feats of navigation have never been surpassed for daring, skill and achievement. In the early days of the American colonies and indeed up to the time when manufactures attracted the surplus population of the rural districts, Americans might almost have been called a race of sailors. They sailed around the world in their merchant ships, fighting French privateers and, when nearer home, dodging English revenue cutters, and in this school of varied hardship and adventure they learned the lessons of seamanship as no others had learned it before. Good sailing ability to navigate a ship to the best advantage was almost as requisite as good gunnery in the naval battles of a century ago, and America's splendid naval record of 1800 to 1815, in combat with French, Barbary pirates and British proves that American seamen could both navigate and fight.

The seamen in vessels trading in American ports in the late 19th century were mostly of foreign origin. Scandinavia supplied a large proportion of them and they were excellent sailors. Laws have been enacted regulating the engagement and treatment of seamen, their claims to pay and their discharge and return to the United States, if abroad. Seamen can no longer be beaten with impunity by brutal shipmasters. The authorities, both civil and criminal, are quick to uphold the cause of a seaman who has a real grievance. Merchant seamen make their contract by signing a written agreement called the shipping articles. This must set forth the voyage, the ports at each end and all other matters which are necessary

to an intelligent understanding of the contract. The contract, when signed, is not absolute evidence of agreement on the part of the seaman, who may prove, if he can, that he was induced to sign by fraudulent representations, or while irresponsible. The law provides penalties for violation of the contract by either party; the amount and quality of provisions while on a voyage are regulated by statute, and the master is bound to pay the wages due, unless he can show that the seaman has been insubordinate or inefficient. A seaman refusing, without good cause. such as illness or other disability, to do the work assigned to him may be put in irons while on board and prosecuted in the nearest United States court. If he deserts he may be arrested and punished by forfeiture of wages and imprisonment. He can justify desertion by proof of cruel treatment. If a seaman is discharged without cause and against his will in a foreign port the master can be punished by six months' imprisonment or a fine of $500. If the seaman, who has done his duty, is willing to be discharged abroad, and the master on his part is willing to let the man go, the master must pay him three months' wages beyond what is due, one-third of which amount goes to a fund for the maintenance of American seamen abroad and for bringing them home. It is part of the duty of American consuls to be vigilant in the protection of American seamen, and the master of a vessel must present his papers for examination by the American consul or consular agent in all ports visited and must explain the reasons for the absence of anyone entered in the list of the crew.

Unfortunately many seamen are ignorant of the provisions of law intended to guard them from abuse and imposition, and the dissipation in which many of them indulge when on shore helps to make them easy victims of unscrupulous boarding-house-keepers and shipmasters, who conspire to rob them of advance money and virtually kidnap them on board vessels on which they had no intention of sailing. This evil is undoubtedly winked at, in some instances, by corrupt officials, who presumably receive a share of the proceeds. Some outrage, greater than usual, calls attention at intervals to the wrongs being perpetrated on seamen, and then there is a brief spasm of public anger and talk of prosecution and reform. This dies out, as a rule, without serious action having been taken and matters go on as before. The lot of the American seaman is, however, immeasurably better than it was in the early part of the 19th century, for now the law is on his side, when invoked, whereas formerly all its power was exerted on the side of the shipmaster, however cruel and unscrupulous.

In England also the seaman has had ample legal protection for over half a century, since the passage of the Mercantile Marine Act of 1850, which lays down minute rules for the government of both masters and seamen. The provisions of the act are very similar to the American laws bearing on the same subject.

The decline of the American merchant marine is attributed largely to the fact that, as a sop to American labor unions, laws were passed obliging vessels carrying the American flag to comply with certain regulations tending to increase the pay of the seamen. Because vessel-owners could hire seamen in foreign ports cheaper than in the United States they have chosen almost universally to fly a foreign flag. The World War, with the indiscriminate sinking of neutral craft by German submarines, stimulated the United States government to inaugurate a heavy shipbuilding era, and the consequent demand for American seamen resulted in increased pay and better conditions.

In 1915 the Congress passed a new seamen's act providing improved conditions as to hours, food, sleep, pay, living quarters and terms of service. One clause called for 75 per cent of the crew to be able to understand orders in English. Penalties for desertion were removed and one-half the wages due were made payable on demand at any port; assignments of wages were voided. On the other hand, the seamen can be dismissed for cause, even in a foreign port, by taking certain action before a United States consul, but to deliberately abandon a seaman in a foreign port is punishable criminally. Seamen's quarters are prescribed to be not less than 16 square feet of deck and 120 cubic feet of air space per individual; washing and toilet arrangements are ordered and medical care and attendance.

SEARCH, Right of, so far as it applies to the homes, persons, papers and effects of American citizens, is regulated by the Fourth Amendment to the Constitution of the United States, which provides that the right of the people to be secure against unreasonable searches and seizures shall not be violated. This provision appears also in State constitutions. A magistrate should issue a search warrant only on evidence sufficient for a reasonable presumption that stolen articles, or articles used in violation of law, such as gambling implements, are to be obtained by the search, or that evidence essential to a prosecution for serious crime may thus be secured. An officer holding a warrant for the arrest of a person charged with crime may enter upon any premises where he believes that person to be, but is responsible both civilly and criminally for abuse of his authority. If an officer makes an arrest without lawful authority he is liable for false imprisonment. Persons not charged with crime may be arrested and detained as witnesses.

The extent of the right of search by belligerents of the vessels of neutrals is a much disputed question, and although it has been agitated for over a century it is far from a comprehensive and satisfactory decision. The assertion by Great Britain, during the wars with Napoleon, of the right to search American vessels on the high seas for alleged deserters from the British navy — some of whom were hanged after being taken from an American man-of-war — provoked the War of 1812. When peace was made, although other points in dispute were adjusted, this question was left unsettled, England, at that time, making no further attempt to interfere with American vessels, and the fall of Napoleon removing the causes which had led to England's high-handed measures.

The Declaration of Paris, signed by the plenipotentiaries of France, Russia, Great Britain, Austria, Prussia, Turkey and Sardinia, 16 April 1856, sought to settle the various questions relating to the right of search, declared

privateering abolished, that the neutral flag covered enemy's goods, except contraband of war, that neutral goods, except contraband of war, were not liable to seizure, even under the enemy's flag, and that blockades, to be binding, must be effective. The United States did not assent to this declaration, and matters were in this condition when the American Civil War broke out.

In 1861 a collision between the United States and Great Britain was nearly caused by the unauthorized action of the commander of a Union war vessel, who stopped the British mail steamer *Trent* on the high seas and took from the *Trent* as prisoners Messrs. Slidell and Mason, commissioners of the Confederate States proceeding to Europe. England made preparations for war, but the government at Washington disavowed the stoppage of the *Trent* and released the commissioners. No privateers were chartered by the United States either during the Civil War or the Spanish-American War. In the latter conflict the United States and Spain proclaimed their intention to adhere to the principles of the Declaration of Paris, and this determination was adhered to throughout the war.

The right to search a neutral vessel for contraband of war is universally admitted, this right, however, being confined to private merchant vessels and not applying to ships of war. The exercise of this right must be conducted with due care and regard to the rights and safety of vessels. All civilized powers also exercise the right of stopping and searching and, if cause be found, seizing or destroying, should resistance be shown, a vessel suspected of piracy or slave trading. The right of search came into prominence again in 1914, 1915 and 1916, when Great Britain went to the limit in stopping neutral vessels in near-by waters and taking them to British ports. The action was violently opposed by many American shippers and was the subject of considerable diplomatic correspondence between the United States and British governments. Owing to the fact that American sympathies were mainly pro-British and that the United States joined the Allies in World Wars I and II, the entire question was dropped, and the conditions of right of search remain more indefinite than ever. See Blockade; Contraband; Declaration of Paris.

SEARCH WARRANT is a warrant requiring the officer to whom it is addressed to search a house or other place therein specified for property therein alleged to have been stolen, and if the same shall be found upon such search, to bring the goods so found, together with the person occupying the same, who is named, before the justice or other officer granting the warrant, or some other justice of the peace or other lawfully authorized officer. It should be given under the hand and seal of the justice and dated. The right is now extended to the search for other articles the possession of which is forbidden by law. The Constitution of the United States declares that "the right of the people to be secure in their persons, houses, papers, and effects, against unreasonable searches and seizures, shall not be violated; and no warrants shall issue, but upon probable cause, supported by oath or affirmation, and particularly describing the place to be searched, and the person or things to be seized."

SEARCHLIGHT. A searchlight is an optical device for projecting light to great distances, either as a signal, or to discover and illuminate any object. It consists essentially of: (1) an intense source of light, and (2) an accurately formed mirror that reflects the light into a substantially parallel beam. The source of light was originally a carbon arc, but between 1906 and 1910, the German inventor, Heinrich Beck, developed the high intensity arc that has since been used almost exclusively. The electrodes for this direct-current arc are made of dense, hard, pure carbon that resists burning when the hot electrodes are exposed to the air. The electrodes for 150 amperes are an 11-mm. negative and a 16-mm. diameter positive. The latter has an 8-mm. core that contains fluorides of the rare earths. When the arc is in operation, a hemispherical crater is formed at the end of the positive, and the gas from the fluorides fills this crater. The passage of the current through the gas heats it to a high temperature, and, accordingly, to high brilliance.

It was thought, previous to about 1910, that pure carbon was the ideal light source, since carbon has the highest melting point of all the elements. In addition, carbon is black, and therefore a good radiator. The maximum brightness of carbon is 13,500 candles per square centimeter, but the 150-ampere high intensity arc gives 82,500 candles per square centimeter, or more than six times as much. This arc, in different sized searchlights, may use from 75 to 500 amperes, and for each electrode there is a particular optimum current. Any departure from rated current will cause a degeneration of the arc toward the pure carbon state if the current is too low, and an increase of current will give a noisy and unstable arc.

The original Beck arc used alcohol burners under the exposed ends of the carbons, so as to immerse them in a neutral and nonoxidizing gas. The dense electrodes developed later made this flame no longer necessary.

The lamp mechanism is usually of the full automatic type. It holds the current constant by changing the arc length through motion of the negative electrode. The positive is rotated from 10 to 15 times per minute in order to obtain uniform walls around the crater. The crater is held at the focal point of the mirror by an optical regulator attached either to the lamp or to the searchlight drum.

One of the first successful searchlight reflectors was the Mangin (Alphonse François Eugene Mangin, 1825–1885) mirror. This reflector was made of glass, and had two spherical surfaces that differed in radius of curvature. The edge was much thicker than the center, which made the mirror a heavy and costly article, since optical glass of suitable quality is expensive. Shop methods of grinding paraboloids, in the United States developed by the Bausch and Lomb Optical Company, eventually rendered the Mangin mirror obsolete. Metal mirrors have become common in military practice: they are made either of some type of stainless steel, ground and optically polished, or they are of a composite type made by depositing rhodium on a heavy metallic backing formed on an accurate glass matrix. The change to metal was made because metal is more resistant to bombing and gunfire than glass. In general, however, metal mirrors fall short of the performance of a silver-backed glass mirror. Rhodium has a reflectance of 0.73, as against 0.88 for silvered glass, while the 60-inch searchlight was found

to give only 650,000,000 candles, as against 800,000,000 before the change was made.

The width and intensity of a searchlight beam may be accurately computed if one knows the brilliance and diameter of the crater, and the reflectance, the focal length, and the diameter of the mirror. The maximum strength of beam occurs in the center of the beam, and is proportional to the central brilliance of the crater multiplied by the plane area of the mirror, due allowance being made for losses of light by absorption and obstruction. The beam width is equal to the angular width of the crater as measured from the center of the mirror, which in the 60-inch searchlight is about 1 degree, 15 minutes. In general, the smaller the searchlight, the smaller the arc, and the less the crater brilliance. The beam strength, therefore, falls off at a faster rate than the decreased plane area of the mirror would indicate.

Practically all paraboloidal searchlight mirrors extend to a 60-degree angle on either side of the axis, and only the light that falls within this "acceptance angle" is useful. It is not economical to extend the mirror beyond this limit, since the radiation from the arc falls off rapidly at larger angles, and not much more light can be collected.

A searchlight arc requires complete protection from wind and rain, and a glass door accordingly is placed over the front of the searchlight. The original doors were of solid plane glass, but these developed heat strains due to unequal heating, and they soon cracked. To overcome this defect, the doors were next made of narrow strips of glass carefully fitted to exclude the weather. These, however, were apt to be broken by the shock of near-by gunfire, and recourse was then had to a solid dome-shaped glass door. The surfaces of this door are spherical, since this is the easiest of all curves to grind, and the two spheres are so selected as to have a minimum dispersing effect on the light passing through. The later development of tempered glass made it possible to use flat glass again in some of the larger naval searchlights.

There are small searchlights that are largely used for signaling. These searchlights use incandescent lamps with concentrated filaments. The filaments are arranged in a single plane, with the coils set as close together as possible, so as to simulate a solid surface. Since the highest brilliance of tungsten is only about 1,600 candles per square centimeter, it is evident that there is a wide gap in performance between tungsten and the best arc. The two types are consequently used in quite different ways.

FRANK BENFORD,
Research Laboratory, General Electric Company.

SEARCY, sär'sē, town, Arkansas, and White County seat; 50 miles northeast of Little Rock, on the Missouri and North Arkansas; the Chicago, Rock Island and Pacific; Missouri Pacific; and Missouri and Arkansas railroads. It is in an agricultural area raising cotton, corn, strawberries, and hay. There is considerable timber. The town has stave and sawmills; cotton gin, warehouse, and compress; bottling works and hatchery; pecan shelling plant; shoe manufacturing plant. Harding College is here. The town was incorporated in 1836. Pop. (1950) 6,024.

SEARING, Laura Catherine Redden (HOWARD GLYNDON), American author: b. Somerset, Md., Feb. 9, 1840; d. Aug. 10, 1923. At 10 she lost the power of hearing and of speech through illness, and was educated at the Missouri Institute for Deaf-Mutes. Later she largely regained the faculty of speech at Clark Institution, Northampton, Mass. She was married to Edward W. Searing in 1876. Her literary career began when she was 18, and during the Civil War she was a newspaper correspondent at Washington. In 1866–1867 she was in Italy as correspondent for the New York *Times* and also engaged in literary work for the Department of Agriculture. During the Franco-Prussian War she wrote *German War Gossip* for the New York *Tribune,* was on the staff of the New York *Mail* in 1868–1876. She published *Notable Men in the "House"* (1862); *Idyls of Battle* (1864); *Sounds from Secret Chambers* (1873). Her daughter published a complete edition of her poems, *Echoes of Other Days,* in 1921.

SEARLE, sėrl, **George Mary,** American clergyman: b. London, England, June 27, 1839; d. July 7, 1918. He came to the United States in 1840; was educated at Brookline High School and at Harvard University, being graduated at the latter institution in 1857. He was computer for the *Nautical Almanac* in 1857 and assistant at the Dudley Observatory, Albany, N. Y., in 1858–1859. In 1859–1862, he was engaged as computer in the United States Coast and Geodetic Survey and in 1862–1864 was assistant professor of mathematics at the United States Naval Academy. In 1866–1868 Mr. Searle was assistant at the Harvard Observatory. He entered the Paulist order in 1868 and was ordained in 1871. In 1895–1897 he was professor of mathematics at the Catholic University, Washington, D.C.; in 1904–1910 was superior general of the Paulist Fathers; in 1910–1911 was engaged in astronomical observations, particularly relative to Halley's Comet, at Newman Hall, University of California. In 1911–1915 Father Searle was stationed at Saint Mary's Church, San Francisco, and after 1915 at the Apostolic Mission House, Brookland, Washington, D.C. He published *Elements of Geometry* (1877); *Plain Facts for Fair Minds* (1895); *How to Become a Catholic* (1905); *The Truth about Christian Science* (1916), and contributed to periodicals.

SEARS, Barnas, American theologian and educator: b. Sandisfield, Mass., Nov. 19, 1802; d. Saratoga Springs, N. Y., July 6, 1880. He was graduated at Brown University in 1825 and later studied at Newton Theological Seminary. He was professor at Hamilton Literary and Theological Institute (now Colgate University) 1831–1833, and afterward studied in Germany, where he assisted in establishing Baptist missions. He was professor and, later, president of Newton Theological Seminary; and in 1855–1867 he was president of Brown University. He was general agent of the Peabody Educational Fund from 1867 until his death. For some years he edited the *Christian Review.* Author of *The Life of Luther* (1850); and several textbooks and translations.

SEARS, Edmund Hamilton, American Unitarian clergyman and poet: b. Sandisfield, Mass., 1810; d. Weston, Mass., Jan. 14, 1876. He was graduated at Union College in 1834 and at Harvard Divinity School in 1837. He was

pastor at Wayland, Mass., in 1839–1840; at Lancaster, Mass., in 1840–1847; editor of the *Monthly Religious Magazine* in 1847–1865; and after 1865 was pastor at Weston, Mass. Author of *Regeneration* (1853); *Pictures of the Olden Time* (1857); *Christian Lyrics* (1860); and *The Fourth Gospel: the Heart of Christ* (1872), his most notable work.

SEARS, sērz, **Isaac,** American patriot: b. West Brewster, Mass., July 1, 1730; d. Canton, China, Oct. 28, 1786. He descended from Richard Sears, who emigrated from Colchester, England, in 1630, and settled in Massachusetts. He was in command of a privateer against the French in 1758–1761, and after losing his vessel settled in New York and engaged in the West Indian and European trade. He became a prominent member of the Sons of Liberty, and was chairman of the first committee of correspondence established in New York. He commanded the troop that raided the printing establishment of James Rivington, editor of the *Royal Gazette*. After destroying the presses, the types were carried away to be cast into bullets. He was a member of the provincial congress in 1783, and also of the State assembly of New York. Having lost his fortune, he shipped as supercargo on a merchant vessel and contracted a fever on the voyage to China, from which he died.

SEARS, Joseph Hamblen, American author and publisher: b. Boston, Mass., April 10, 1865; d. Kingsport, Tenn., Feb. 15, 1946. He was graduated from Harvard in 1889, and later published, among other works, *The Governments of the World Today* (1893); *None But the Brave* (1902); and *Leonard Wood* (1916).

SEARS, Lorenzo, American rhetorician: b. Searsville, Mass., April 18, 1838; d. Providence, R. I., Feb. 29, 1916. He was graduated from Yale in 1861, from the General Theological Seminary, New York, in 1864, and was engaged in pastoral duties in New England in 1864–1885. He was appointed to the chair of rhetoric and English literature at the University of Vermont in 1885, which he filled until 1890, when he occupied that of rhetoric and American literature at Brown University until 1906. He has published *History of Oratory* (1896); *The Occasional Address, Its Literature and Composition* (1897); *Principles and Methods of Literary Criticism* (1898); *American Literature in the Colonial and National Periods* (1902); *Seven Natural Laws of Literary Composition* (1904); *Makers of American Literature* (1904); *Wendell Phillips, Orator and Agitator* (1909); *John Hancock, the Picturesque Patriot* (1912); *John Hay, Author and Statesman* (1914).

SEARS, Taber, American artist: b. Boston, Mass., 1870; d. New York City, Oct. 18, 1950. He was educated at the Boston Museum of Fine Arts, School of Arts and at the Jullian Academy, Paris, and studied under Jean Paul Laurens and Luc Olivier in Paris, as well as studying at Rome and Florence. He has specialized in mural paintings and in designs for stained glass windows. His mural paintings include *The Spirit of Niagara* (Buffalo Historical Society); *Among the Nations* (New York City Hall); frieze of the Apostles (Epiphany Church, Pittsburgh), etc.

SEARSPORT, town, Maine, in Waldo County; altitude 50 feet; about 30 miles southwest of Bangor; terminus of the Bangor and Aroostook Railroad. Its chief industries are boat building, ice-gathering and shipping potatoes. It was a seaport of importance in the days of sailing vessels. The Penobscot Marine Museum contains many relics and papers of the days when the town was a shipbuilding and marine center. The home of Lincoln Colcord, well-known writer of sea stories, is here. Pop. (1940) 1,319; (1950) 1,457.

SEAS, Freedom of, a term of international law and diplomacy employed to describe the legal nature of the high seas, in respect to the right of every nation to navigate their waters freely beyond a certain limit, usually three miles from the coast, without being subject to the control of any nation. This freedom, now so well established, was not universally recognized in earlier times. As late as the 15th century Portugal asserted sovereignty over the Indian Ocean, and a large part of the Atlantic Ocean south of Morocco, while Spain asserted an equal right over the Pacific and the Gulf of Mexico, and the pope supported their claims. In later times Great Britain asserted extravagant claims over the English Channel and certain great arms of the sea which washed the shores of the British Isles. Still later other nations, from time to time, asserted more or less jurisdiction over certain waters of the open seas. Thus the United States undertook to exclude other nations from killing fur seals in the Bering Sea many hundreds of miles from the American coast, but the question having been submitted to an international tribunal of arbitration, the tribunal decided against the American claims. Some nations claim and exercise jurisdiction in respect to fisheries and revenues over their littorals extending far beyond the three mile limit, and although this assertion has occasionally produced irritation and conflict it has usually been acquiesced in. Formerly certain nations claimed and exercised the right to control great bodies of the open sea connected by straits within their jurisdiction. The claims asserted by Denmark over the Baltic Sea were a well-known instance, and her claims were not finally abandoned until the middle of the 19th century.

Hugo Grotius in his *Mare Liberum* published in 1609 in answer to John Selden's attack upon the freedom of the seas revived the doctrine of the Roman law that there could be no property in anything which could not be effectually occupied; hence the oceans were free to the navigation of all, subject to the control of no nation. Since Grotius' time the general principle of the freedom of the seas in time of peace has been universally recognized and except for the depredations of pirates and slave traders it has been generally enjoyed for purposes of navigation. This, of course, does not mean that a nation cannot restrict the maritime trade between its own continental ports or between itself and its colonies to its own citizens and to vessels flying its own flag, or that it cannot prescribe conditions under which foreign ships may enter or depart from its own ports. What freedom of the seas in time of peace means is the right of the ships of all nations to navigate freely the high seas outside the ter-

ritorial waters and beyond the three-mile marginal sea without being subject to the right of search or molestation by the vessels or authorities of any nation.

In time of war no such freedom of navigation is recognized. This freedom is limited by the admitted right of belligerents to intercept and confiscate articles of contraband on their way to the enemy and to prevent by means of lawful blockade all intercourse or trade in any and all goods, whether contraband or not, with the enemy. To this end, the public vessels of a belligerent may stop and search on the high seas any neutral vessel with a view to ascertaining its nationality as well as the character and destination of its cargo and, under certain conditions, both may be confiscated or even destroyed. During the World War certain belligerents, notably Great Britain, went to the length of taking neutral vessels into distant ports for the purpose of conducting the searches, against all of which neutral governments vigorously protested. Mails from neutral steamers were likewise taken in, searched, censored and detained. Many neutral vessels were also stopped and persons of enemy nationality were taken off and imprisoned. Mines were sown in the open seas, first by Germany and then by Great Britain, and a goodly number of neutral merchant vessels innocently navigating the high seas were destroyed. Germany, and to a less extent Great Britain, also declared great areas of the open seas to be war zones, "barred zones," "danger areas" and the like (see WAR ZONES). The zones proclaimed by Great Britain could only be navigated with great danger and the Germans even went to the length of deliberately sinking all ships which entered the zones proclaimed by their government. In the enforcement of their blockade measures Great Britain and France applied the doctrine of continuous voyage or ultimate destination to trade with the enemy through neutral ports and thus effectually, it was charged, blockaded neutral ports. The doctrine of contraband was extended to include nearly everything that could be carried by sea, the distinction between conditional and absolute contraband was abolished and the rule of ultimate destination was applied to both classes of contraband without distinction (see CONTRABAND). The German government went even further and systematically sunk many hundreds of neutral vessels, including even fishing vessels, hospital ships and those engaged in missions of mercy and philanthropy, in spite of the immunity which international law assures them. By these and other acts the principle of the freedom of the seas, as it has been heretofore understood, was seriously infringed upon and loud protests were made by neutrals. The German government likewise never ceased to denounce the conduct of Great Britain and maintained that it was fighting for the freedom of the seas — a profession which in virtue of its own lawless conduct was more hypocritical than sincere.

While the United States was still a neutral the President denounced these infringements upon the freedom of the seas, and in an address to the Senate declared that the "paths of the sea must alike in law and in fact be free" and that "the freedom of the sea is the *sine quâ non* of peace, equality and co-operation." As one of the 14 conditions of peace which he announced to Congress on 8 Jan. 1918 was the following: "Absolute freedom of navigation upon the seas, outside territorial waters, alike in peace and in war, except as the seas may be closed in whole or in part by international action for the enforcement of international covenants." It was pointed out at the time that the seas were already free in time of peace and his proposal must, therefore, apply only to the freedom of the seas in time of war. There was a difference of opinion as to the exact meaning of the proposal for "absolute" freedom of navigation and it was the subject of much discussion. Literally interpreted it would mean the abolition of the belligerent right of blockade, at least of commercial blockade, the right to seize contraband of war going to the enemy, the surrender of the right to prevent unneutral service and perhaps of the right to capture enemy private property at sea and to destroy enemy merchant vessels. Great Britain and France in their replies to the President's proposals accordingly stated that since the point relating to the freedom of the seas was "open to various interpretations," some of which they could not accept, they must, therefore, "reserve to themselves complete freedom on the subject when they enter the peace conference." It is obvious that a freedom of the seas which would deprive a belligerent of these weapons would amount in effect to a prohibition of naval warfare altogether and would place a naval power in a position of great disadvantage in comparison with a military power. It is well known that the exercise of these rights contributed more than anything else to the defeat of the Confederacy during the Civil War and it is doubtful whether without them the Allies could have forced Germany into submission during the World War. There seems little likelihood, therefore, that the great naval powers, including the United States, will be willing to pay such a price for an absolute freedom of the seas. Much may be said and has been said in favor of the immunity of private property from capture at sea and even in favor of the abolition of purely commercial blockades. The British government even went to the length of proposing at the second Hague Conference that contraband be entirely abolished and that neutrals be allowed to carry without molestation what they will to belligerents, and this proposal received the support of 26 states. But as yet no agreement has been reached and it does not seem likely that as to some of the proposals any agreement will be reached in the near future. As the term is now understood, therefore, freedom of the seas in time of war means nothing more than the liberty of neutrals to trade with belligerents subject to the long-established restrictions in respect to blockade and contraband. To be sure, these restrictions should be more precisely defined and limited so as to prevent in the future such grave infringements as were committed upon the rights of neutrals during the late war. As to the rights of belligerents to sow mines in the open seas beyond their territorial waters, to assert control over great areas of the sea under the name of "war

zones," and to destroy systematically and generally neutral merchant vessels, they should be forbidden altogether. These measures would not ensure "absolute" freedom of the seas but they would remove the most irritating sources of controversy, which is probably all that can be expected for the present. After the war the subject of the freedom of the seas was avoided at the Washington Conference of 1922, and at the Geneva Conference of 1927. No definite action towards clarifying the points at issue was taken by the League of Nations.

JAMES W. GARNER,
Professor of Political Science, University of Illinois.

SEASHORE, Carl Emil, American psychologist: b. Mörlunda, Sweden, June 28, 1866; d. Lewiston, Idaho, Oct. 16, 1949. He was graduated at Gustavus Adolphus College, St. Peter, Minn., in 1891 and from Yale University in 1895. He was assistant in the Psychological Laboratory at Yale in 1895–1897; and from 1897 was associated with the faculty at the University of Iowa, where he was professor of psychology from 1902, head of the department of philosophy and psychology 1905–1937, and dean of the graduate college, 1908–1936. He invented many psychological instruments, among them the voice tunoscope, spark chronoscope, psycherogograph, audiometer, sound perimeter and multiple recorder, and originated the Seashore Measures of Musical Talents in 1919 (revised, 1939). He edited the University of Iowa's *Studies in Psychology;* was joint editor of the *Journal of Educational Psychology;* and consulting editor of the *Psychological Review.* He was author of *Psychology in Daily Life* (1913); *The Psychology of Musical Talent* (1919); *Introduction to Psychology* (1922); *A Preview of College and Life* (1938); *Why We Love Music* (1941); *In Search of Reality in Music* (1947).

SEASICKNESS, an affection attended with nausea and other disagreeable sensations produced by the motion of a vessel. Its causes and etiology are as yet imperfectly understood. Some refer it to causes dependent upon the altered or affected functions of the nervous centers; others to the regurgitation of bile into the stomach; and still others to irritation of the liver by the unusual movements of the body, increased secretion of bile being secondary. Probably each of these views contains something of the real explanation of the disorder.

When a landsman goes to sea, the movements of the ship, and the shifting lines and surfaces, unsettle his visual stability, as the different inclinations of the plank he stands on unsettle his muscular sense. The consequent derangement of these faculties reacts upon the nervous centers and through the latter upon the viscera, thus producing nausea and vomiting. Recollection of the disturbing sensations, together with the emotional state which they originally excited, may itself become an efficient cause, at least in individuals, of peculiarly irritable stomachs, or of highly sensitive nervous systems; for this plays downward upon the sensorial centers in such a manner as to excite in them the same condition as that which was originally produced through the medium of the sensory nerve. This may explain why certain individuals show all the symptoms of seasickness on going aboard a vessel perfectly at rest. So, no doubt, imagination is a potent and important factor in the case. The fact that visual impressions predispose travelers to seasickness suggests that a susceptible individual might do well to close his eyes, when on deck, and thus overcome this unpleasant sensation.

But perhaps the chief causes of seasickness may be summed up thus: (1) Effusion of blood to the brain; (2) disturbance of the digestive system; (3) over-eating, and also under-eating. Many preventive measures referring to the construction and arrangement of vessels have been tried with little success; yet experiments with vessels having a swinging saloon, designed to preserve equilibrium in any sea, and vessels with a breadth intended to minimize the rocking motion, show that nautical men and shipbuilders are becoming alive to the interests and comfort of travelers. Preventive measures regarded from the patient's point of view are practically limited to the regulation of diet before a voyage. The diet for some days previously should be plentiful, but of light and nutritious character. Above all, the bowels should not be constipated and food should not be taken for at least five or six hours before going on board, although a cup of strong coffee just before embarking will prove beneficial as a slight stimulant. On the ship a position as near the center as practicable is to be preferred.

Three or four drops of chloroform on lump-sugar may prevent vomiting and a suitable dose of bromide of soda and antipyrine will often give further relief. Many medical men consider that if drugs must be taken, the best all-around remedy is chlorobrom (not chloroform), a compound of chloralamide and bromide of potassium, while some prefer five grains of bromide of ammonia.

SEASIDE, unincorporated village, California, in Monterey County, altitude 4-400 feet; on the Southern Pacific Railroad, three miles east of Monterey. Situated on the south shore of Monterey Bay at the base of the Monterey Peninsula, it is mainly a residential community. Founded in 1900, its government is by local districts and through county supervisors. Pop. (1950) 10,226.

SEASONS, the four grand divisions of the year. Spring is from the vernal equinox, when the sun enters Aries, to the summer solstice; summer is from the summer solstice to the autumnal equinox; autumn is from the autumnal equinox to the winter solstice; winter is from the winter solstice to the vernal equinox. The earth's axis is inclined to the plane of the ecliptic at 66½ degrees, and as the earth moves round the sun in the course of a year, the northern hemisphere is turned to the sun in summer (most so at the summer solstice); at the equinoxes the line of light and shade on the earth passes through the poles, and at the winter solstice the Northern Hemisphere is turned from the sun. It is evident that the characters of the seasons are reversed to inhabitants of the Southern Hemisphere. See AUTUMN; EARTH; SUMMER; SPRING; WINTER; METEOROLOGY.

SEASONS, The, a poem in blank verse by James Thomson (q.v.), which has been characterized as "the classic of descriptive poetry." The evolution of the poem is traced in *Winter,* published in 1726; *Summer,* 1727; *Spring,* 1728; and *Autumn,* 1730. In 1744 the poet issued a new edition with extensive additions and alterations as *The Seasons.* Departing from the severe classic style of Pope and his school, Thomson relied solely on an appeal to the external beauties of nature, and by simplicity and truthfulness inaugurated a new era in English poetry which gathered strength in Gray and Cowper and culminated in Wordsworth. Not only in England was he imitated by his contemporaries—notably by Goldsmith in *The Deserted Village*—but numerous translations appeared on the continent of Europe, while in *Les Saisons,* Saint-Lambert (1716–1803) copied Thomson in a poem praised by Voltaire, and which was popular for half a century.

SEATON, Sir John Colborne, 1st Baron of. See Colborne, Sir John.

SEATON, William Winston, American journalist: b. King, William County, Va., Jan. 11, 1785; d. Washington, D.C., June 16, 1866. He engaged in journalism at 18 and edited various newspapers until 1812 when he became associated with his brother-in-law, Joseph Sales, Jr., with whom he was editor and owner of the *National Intelligencer* at Washington. From 1860, until just prior to his death, he was sole editor and manager. In 1812–1820 Seaton and Gales were exclusive congressional reporters, one attending the sessions of each house. Their publications are highly authoritative and of great historical value. They include *Annals of Congress, Debates and Proceedings of the Congress of the United States from March 3, 1798, till May 27, 1824,* 42 vols., (1834–1856); *Register of Debates in Congress from 1824–1837,* 29 vols., (1827–1837); *American State Papers,* 21 vols., (1832–1834).

Consult the *Life* by his daughter (1871).

SEATTLE, Wash., largest city of the Pacific Northwest, county seat of King County, important seaport, and the world's youngest city of its size, is situated on the eastern shore of Puget Sound, between Elliott Bay on the west and Lake Washington on the east; 865 miles by water north of San Francisco, Calif., 185 miles by rail north of Portland, Oreg., 123 miles by rail south of the Canadian boundary. The city area is 104.41 square miles, of which 35.91 square miles are water.

Population.—The population of Seattle in 1870 was 1,107; in 1880, 3,533; in 1890, 42,837; in 1900, 80,671; in 1910, 237,194; in 1920, 315,312; in 1930, 365,583; in 1940, 368,302; and in 1950 467,591.

Location.—Seattle's setting is one of great natural beauty, looking to the west across the wide reaches of Puget Sound to the lofty, rugged range of snow-capped Olympic Mountains. To the east, across Lake Washington, the foothills rise sharply to the Cascade Range with major peaks—Mount Baker (10,750 feet), Glacier Peak (10,436 feet), and Mount Rainier (14,408 feet)—visible from many parts of the city. Since these majestic peaks are viewed from approximately sea level, they are most impressive. Lake Washington, 22 miles long, 4 miles wide, 225 feet maximum depth, and with a shore line of 80 miles bounds the city entirely on the east.

The general contour of Seattle is hilly, ranging from sea level to 514 feet on the West Seattle crest. Queen Anne Hill, a prominent residential district, is 464 feet above sea level. The valleys have a general north and south trend, and the "seven hills" upon which the city is built include First, Beacon, Capitol, Queen Anne, Wallingford, Madrona, and West Seattle hills.

Cable and electric railroads that once served the city have been replaced by modern trackless trolley cars and mobile busses, operating on 300 miles of streets. By regrading, some of the hills obstructing business districts have been leveled and earth has been removed to fill low places and tidelands now forming some of the principal industrial districts and locations. More than 34,000,000 cubic yards of earth have been moved, largely by hydraulic process, and hills up to 130 feet in height have been leveled. The main business district occupies the relatively level area paralleling the waterfront on Elliott Bay and terraced up to about 8th Avenue. The general residential districts are on hills and slopes providing perfect drainage and a wide variety of mountain and water views. While there are numerous modern apartment houses, the great majority of homes are detached dwellings with yards attractively planted with shrubbery and flowers. In addition to Lakes Washington and Union, Green Lake, about 4 miles in circumference, in the north-central district of the city, is surrounded by parks, playfields and charming residences.

Climate.—The prevailing air currents which reach Seattle from the Pacific Ocean give the city a mild and moderately moist climate. The temperature reaches 90 degrees or more on the average of only once per year, and the city has no record as low as zero. The average daily minimum temperature in January is 36 degrees, while the average daily maximum in July is 74 degrees. The normal annual precipitation over a 50-year period is 34 inches, mostly as rain, distributed over 149 days of measurable amounts. The city experiences no extremes of heat or cold, floods or droughts.

Government.—The city government is by a mayor and 9 councilmen, elected every four years, with comptroller, treasurer, corporation counsel, and various boards, commissions and departments.

The municipal water supply is pure mountain water impounded on Cedar River in the Cascade Range. Reservoirs have a capacity of 365,370,000 gallons; daily consumption averages 79,700,000 gallons.

Seattle City Light is the second largest municipal plant in the United States, with a hydro capacity of 224,000 kw. and steam capacity of 38,000 kw. Additions under construction in 1950 were expected to provide a total capacity of 572,000 kw. by 1953, and of 712,000 kw. by 1956. City Light also provides power for Seattle's municipally owned transit system, operating over 300 "trackless trolley" cars.

Public Buildings.—Seattle has 250 churches, including Chinese, Japanese, Finnish, Jewish, Scandinavian, German, and White Russian, and is the see of the Roman Catholic bishopric of Seattle. Among the attractive religious edifices

are Saint James Cathedral, Saint Mark's Cathedral, Plymouth Congregational Church, First Baptist Church, First Church of Christ Scientist, First Presbyterian Church, University Temple, and Temple de Hirsch. Among other public buildings of note are the Civic Auditorium, Armory, L. C. Smith Building with its 42-story tower, Olympic Hotel (built at cost of $5,000,000), Medical-Dental Building, Dexter Horton Building, County-City Building, Public Safety Building, Telephone Building, Northern Life Tower, Shopping Tower, Exchange, Alaska and Central Buildings, Arctic Club, Washington Athletic Club, Sunset Club, Rainier Club. Among the leading theater buildings are the Orpheum, Metropolitan, Fifth Avenue, Paramount, and Music Hall.

Public Markets.—The public markets of Seattle are noted attractions for visitors, and are well patronized by residents. Here may be found fresh produce from the many farms and gardens surrounding the city or brought from the islands or mainland across the sound over the network of ferries operating from the port. Fish markets and seafood eating houses are found on the waterfront, where salmon, halibut, sole, the famous Dungeness crabs, many kinds of oysters and clams, and other salt-water fish may be procured.

Industries.—The growth of Seattle's industries has kept pace with its growth in population. According to the United States Census of Manufactures (1947), there were 1,221 industrial establishments in the Seattle Metropolitan area, employing 54,770 persons who received salaries and wages totaling $171,221,000. Diversification of manufacture is indicated by classification into lumber products, furniture, stone, clay, glass, metals, metal products, machinery, electrical equipment, aircraft, transportation equipment, instruments, foods, textiles and apparel, pulp and paper products, printing and publishing, chemicals, rubber products and leather goods. The city's largest industrial plant, the Boeing Airplane Company, has 18,000 employees and a plant investment of some 40 million dollars.

Foreign Trade.—The unexcelled harbor of Seattle and its strategic location have been particularly favorable to the development of waterborne commerce. From the early days when windjammers sailed into Elliott Bay for lumber and carried trade to the seven seas until the era of huge steamers and motorships, Seattle has been important in foreign trade.

By the northern trade routes, Seattle is 1,100 miles nearer to Japan than are the California ports, whose ships follow the southern routes via Hawaii. During the period between World Wars I and II, swift vessels plying between the Orient and Seattle brought rich cargoes of silk which were rushed by fast freight to manufacturing centers on the Atlantic coast.

While World War II and subsequent unrest in the Orient affected trade with those countries, Seattle's water-borne commerce in 1949 carried 479,884,568 pounds of imports and 468,380,816 pounds of exports. These imports were received from 46 different foreign countries, while exports left the port for 72 different countries. Leading imports in order of poundage were: paper and newsprint, fruit and fruit preparations, bananas, unmanufactured wood, tinplate, turnplate, scrap iron, nonmetallic minerals, sawmill products, cocoa, coffee, tea, chocolate, coal and related fuels, coal tar products, and vegetable fibers. Leading exports were: grains and preparations, wheat flour, coal and related fuels, steel mill products (ingots, billets, bars, and sheets), sawmill products (lumber), logs, posts, poles, pilings, building cement, and petroleum products.

Banks.—Some fifteen banking houses are represented in Seattle, a number of which have branches in various districts. One bank, the Seattle-First National, has 12 branches in the city and 48 banking offices in the State of Washington. There is also a Federal Reserve bank. Total bank clearings in 1949 in Seattle were $5,794,612,496.

Transportation.—Seattle is served by four transcontinental railroads — Great Northern, Northern Pacific, Union Pacific, and Chicago, Milwaukee, St. Paul and Pacific, with their various connections. Several important steamship lines reach the city. Seattle is on the Pacific Highway (US 99) and connects with various east-west highways and with many stage and trucking lines. It is the terminus for a number of important airlines serving the United States, Canada, Alaska, Hawaii and the Orient.

Canals and Bridges.—Lake Washington is connected with Puget Sound by a ship canal more than 8 miles long, 150 feet wide, and with 36 feet depth of water. Between lake and sound it connects through Lake Union, in the heart of the city, 2 miles long by ¾ mile wide, affording additional dock facilities. Lakes Washington and Union are on the same level, but the fresh waters of the latter are joined with the salt waters of Puget Sound through a set of locks, second in size only to those of the Panama Canal—with one chamber 80 by 825 feet and another 30 by 100 feet, with a depth of water from 36 to 42 feet. The larger chamber requires 25 minutes and the smaller 15 minutes for the passage of a ship. This canal, opened in 1916, extended Seattle's waterfront from 40 to 140 miles, adding a fresh water, nontidal harbor unique in the world. Through straightening the Duwamish River at the south end of Elliott Bay, another artificial waterway 5 miles long, 300 feet wide, and 30 feet deep at low tide taps a level district that is becoming an important manufacturing section.

A floating bridge (completed in 1940) of concrete pontoons, considered one of the engineering wonders of the world, spans Lake Washington from the city to Mercer Island and thence across the East Channel and Mercer Slough to the eastern shore, forming one of the principal highway entrances to Seattle. The Lake Washington floating bridge is 6,500 feet in length, 60 feet in width, and has 25 concrete pontoons, anchored with 65 special steel cables. The depth of water under this bridge is 210 feet, but in a 55-miles-per-hour wind the lateral movement is only 6 inches, with no measurable vertical undulation. The George Washington Memorial Bridge, on Aurora Avenue, spanning the Lake Washington Ship Canal at the west end of Lake Union, has a vertical clearance of 135 feet to permit passage of the tallest ships. Several drawbridges also span the canal.

The Port of Seattle.—Seattle's major harbor and airport facilities are administered by the Port of Seattle, a municipal corporation embracing a territory with boundaries the same as King County, but independent of city, county or

state agencies. It is governed by a board of three port commissioners, elected for six-year terms. Of more than 80 piers and terminals operated on the Seattle waterfront, it owns eight of the largest. It also owns and operates Foreign Trade Zone No. 5, the huge Seattle-Tacoma International Airport at Bow Lake, located between Seattle and Tacoma, and the Salmon Bay Fishing Terminal.

By reason of its strategic geographic location on the great circle routes, Seattle is the closest American port to the Orient, Hawaii, and Alaska, and has one of the best natural, protected harbors in the world. It is 125 nautical miles from the Pacific Ocean by waters that are wide, deep and free from hazards to navigation. The entrance at the Strait of Juan de Fuca is 15 miles wide, and the width of the channel to Seattle varies from 3 to 25 miles in width and from 25 to 150 fathoms in depth. There are two harbors at Seattle, one of fresh water including Lakes Washington and Union, with an area of 51 square miles and a shoreline of 140 miles. The salt-water harbor consists of Elliott Bay, East, West and Duwamish waterways, and portions of Puget Sound. The total salt-water harbor area is 5,300 acres with a shore frontage of 54 miles. Here may be seen craft of every size and kind from majestic ocean liners to private yachts and commercial fishing boats.

In 1949, Foreign Trade Zone No. 5 was established. It is maintained and operated by the Port of Seattle as a service to foreign traders. Here goods from foreign countries may be entered without payment of duty, stored indefinitely, manipulated in almost any way, and reshipped abroad with no duty on re-export.

Airport.—Also under the management of the Port of Seattle is the Seattle-Tacoma International Airport, dedicated in 1949 and acclaimed one of the world's finest airports. This terminal, constructed at a cost of $11,000,000, serves four major airlines—Northwest, United, Pan American and Western. It contains federal installations, including weather station, post office, Civil Aeronautics Administration regional control office, and offices of the United States Immigration Service, Customs Service, Public Health Service and Department of Agriculture. Its field has three runways, respectively 7,500, 5,600, and 5,093 feet in length.

Education.—The University of Washington (established in Seattle in 1854) is one of the nation's larger educational institutions. Its 600-acre campus overlooks Lake Washington and Lake Union, with magnificent views of the Cascade Range and Mount Rainier. It enrolls about 15,000 students and has about 1,000 full-time professors and instructors. Included in the university are 50 schools and colleges. Its attractive buildings are valued at $50,000,000, of which some $25,000,000 has been expended since World War II. This includes the new Medical-Dental Center, costing $10,000,000, and a new engineering building and student union. Its stadium seats 55,000, and the Hec Edmundson Athletic Pavilion seats 13,000. A new crew house, completed in 1950, houses 24 shells and furnishes facilities for Washington crews which have set national and international records.

Seattle had 75 grade and special public schools, 7 junior high schools and three more under construction, 8 high schools, and 1 vocational school in 1950. Since the University of Washington is located within the city limits it is possible for a Seattle student to advance from kindergarten to his doctorate without leaving the city. The average public school attendance is 58,000; there were 2,190 teachers in 1950, and the annual expenditure per pupil is $215.24. The city has a number of private, parochial and cultural schools. Seattle University, a Catholic institution, has an enrollment of some 2,500 students. Seattle Pacific College, Protestant, has an enrollment of more than 1,000 students and a campus of eight acres, with 10 main buildings. Other schools include Cornish School of Music, Dance, Art, Drama; St. Nicholas, Helen Bush, Forest Ridge Convent and Holy Names Convent (schools for girls); and St. Joseph's and Lakeside (schools for boys).

Libraries.—The Seattle Public Library system consists of the central Carnegie library and 12 branches, including the municipal reference library, 1 mobile branch, and 13 stations. The collection contained (1950) about 768,536 volumes, 5,128 talking books for the blind, 3,470 phonograph records, and 4,156 pieces of sheet music. Circulation is over 2,600,000 volumes a year.

Press and Radio.—Seattle has one morning and one evening daily newspaper, with circulations of 269,000 and 238,000 respectively, for Sunday editions; a twice-weekly shopping news distributed to all residences in the metropolitan area (circulation, 135,000); numerous publications of special groups; several foreign-language papers; and a number of community papers. It has eight radio broadcasting stations, four of which are outlets for national networks, and one television station.

Parks and Recreation Centers.—The system of parks, boulevards and playfields in Seattle is unusually complete for the size and age of the city. It is operated by a board of park commissioners of 5 members, appointed by the mayor for a term of five years. It has control of approximately 3,000 acres of park properties, including 55 playgrounds, 9 field houses, 45 parks, 25 miles of boulevards, three 18-hole and one 9-hole golf courses, zoological gardens, an art museum, one warm-water swimming pool, 10 bathing beaches, two camps, and an arboretum of approximately 267 acres maintained by the University. Major park areas are Seward Park, 207.64 acres; Woodland Park, 188 acres, containing a modern zoo; Volunteer Park, 45 acres, containing the Conservatory and Seattle Art Museum; and Lincoln Park, 130 acres. Chief view parks are Kinnear, Kerry, Belvedere, Dwamish Head and Magnolia. Connecting the thickly forested parks in various parts of the city by winding drives with easy gradients, now skirting the Lake Washington shore or overlooking the waters of Puget Sound and the mountains, the scenic boulevard system within the city is one of the most attractive in the United States. Connecting with the Lake Washington Boulevard is a continuous drive of 52 miles around Lake Washington, with ever-changing vistas and views of charming suburban residential districts.

Charitable and Correctional Institutions.—Public support of charitable and character-building institutions is provided through a community fund which investigates the needs of member institutions, and assigns to each a definite sum for its annual operation. The total of

these requirements is then given by the public in an annual fund-raising effort. A public appeals board passes upon the merit of other campaigns or solicitations for contributions from the public.

Seattle has a number of hospitals, including the Seattle General, Providence, Saint Luke's, Maynard, Swedish, Virginia Mason, Columbus and Children's Orthopedic. King County maintains Harborview Hospital at 9th Avenue and Jefferson Street, and the federal government maintains the United States Marine Hospital at 14th Avenue South and Judkins Street.

Societies for Civic Betterment.—The Seattle Chamber of Commerce, with a membership of 4,000 businessmen, is the clearinghouse for many of the city's commercial, industrial and civic problems. Departments include those interested in Alaska, state development, foreign trade, transportation, retail trade, publicity, tourist promotion, military and aviation affairs, taxation, legislation, etc. The Seattle Junior Chamber of Commerce is also an active organization. Other semipublic organizations include the Manufacturers' Association, the Merchants Exchange, Seattle Clearing House and numerous trade groups and labor unions, together with technical groups and local improvement clubs. Service clubs are well represented. The leading social clubs include the Rainier, Arctic, Washington Athletic, and College clubs for men, and Sunset and Women's College clubs for women. Musical organizations include the Seattle Symphony Orchestra, Seattle Civic Opera, and Ralston Club. The Music and Art Foundation has a membership of 2,000 women in 32 units, which promote cultural activities. In addition, there are various groups which stage musical and dramatic performances throughout the year. Grouped around the University of Washington are several "little theaters," including the unique Showboat, Repertory, and Penthouse theaters.

Pageants, Celebrations and Conventions.—Direction and coordination of Seattle's pageants and celebrations are carried on by Greater Seattle, Inc., a community organization supported by public contributions and memberships. Created primarily for the promotion of Seattle's centennial celebration (1951–1952), it stages annually in August the Seattle Sea-fair, a gigantic carnival of water sports, including water skiing, crew regattas, and speedboat and yacht racing, replete with pageantry. Water events are of special interest, since Seattle has more small boats registered than any other city of the United States except New York, and has accessible 25,000 miles of inland waterways. Because of Seattle's scenic attractions and many opportunities for sports and recreation, it entertains many international, national and regional conventions. Hotel accommodations are available for as many as 10,000 delegates. The Civic Auditorium provides seating and committee rooms for about 7,500 delegates.

Tourist Travel.—The wide variety of tourist attractions, both within Seattle and easily accessible from the city, brings throngs of visitors, making the tourist trade an important source of income. Important tourist attractions within the city include: Lake Washington Floating Bridge; Volunteer Park with Seattle Art Museum, Conservatory, and formal gardens; waterfront with varied attractions, including Ye Old Curiosity Shop, where curios from all over the world may be purchased, and the Aquarium, with its displays of salt-water plant and animal life; United States government locks, second largest in the world; University of Washington campus, with museums and landscaping; view from 42-story Smith Tower; Lake Washington Boulevard drive, with University of Washington Arboretum and Seward Park; Woodland Park and Zoological Gardens; view of harbor from Marine Drive; and public markets.

History.—On Nov. 13, 1851, the first settlers landed from the schooner *Exact* at a point within the present limits of Seattle, which they named New York, and to which was added the Indian word *Alki,* meaning "by and by." Less than two months earlier, Capt. Robert C. Fay, John N. Low, David Denny, and Leander Terry had arrived by boat in Elliott Bay, and the latter two had remained to build a cabin on the south headland of the bay. On Feb. 15, 1852, claims were located on the east shore of Elliott Bay, including the site of present-day Seattle's business district. The village was named for Seathl, a friendly Indian chief of the Dwamish and Suquamish tribes; and on May 23, 1853, a chart of the "Town of Seattle" was recorded with the Territory of Olympia. Its first church was organized by the Rev. David E. Blaine in October 1853, and the first school was opened in the following year.

In January 1856 the town (population 300) withstood an Indian uprising which was quickly quelled with the aid of the guns of the sloop-of-war *Decatur.* The discovery of gold two years later on the Fraser River to the north in Canada resulted in a stampede of prospectors through Seattle, but only a few remained to settle there. In 1861 the Territorial University (now the University of Washington) was located in Seattle after persistent lobbying by the town's citizens in the territorial legislature. Its first wooden structure was built on a tract of land donated and cleared by the townspeople, and its only instructor, Asa Mercer, personally canvassed the Puget Sound region in search of the first students. In 1863 the first issue (four pages) of the weekly Seattle *Gazette* (which later became the *Post-Intelligencer*) was produced by J. R. Watson, and the town's first hospital was opened. Telegraph lines reached there in 1864, and in 1866 the first of two groups of young women from good families—the "Mercer girls"—were persuaded by Asa Mercer to come from the Atlantic coast to find husbands among the male population. Seattle was incorporated as a town in 1865 and reincorporated as a city in 1869. Regular steamship service with San Francisco was inaugurated in 1875, and in 1883 the first major railroad reached Seattle after the entire citizenship had wielded pick and shovel to build a line threatening to connect with the Canadian Pacific.

Riots against Chinese laborers imported to work on the railway and in the mines nearby brought a period of violence to the growing community in the 1880's, but these were quelled by local vigilance committees in 1885. Cable cars and electric lights both made their appearance in 1888. Then, in June 1889, the young city was practically wiped out by the great fire which destroyed 60 blocks of business and residential districts with an estimated loss of $15,000,000. Soon, however, new, more permanent structures were built over the ashes of the fire, and the modern city began to take form. In 1893 the Great Northern Railway made Seattle its western ter-

minus, connecting with a line of giant ocean liners. Discovery of gold in the Klondike, with the much publicized arrival, on June 17, 1897, of the steamer *Portland* with a "ton of gold" (about $800,000 worth) brought a new era to Seattle. During the next decade her population almost trebled as the city's boundaries were extended to include the West Seattle, Ballard, and Columbia City districts in 1907, and Georgetown in 1910. In 1909 the city held its world's fair, the Alaska-Yukon-Pacific Exposition, which attracted an estimated 3,750,000 visitors with a resultant further growth in population.

The coming of other railway lines, the opening of the Panama Canal which provided a short water route to the Atlantic coast and Europe, the inauguration of transpacific steamer service, the development of the state's natural resources, and the harnessing of vast hydroelectric power all added to the wealth and growth of the city. During World War I, Seattle led the nation in shipbuilding and marked industrial growth; its port was second only to New York in volume of shipping. During the years between the world wars, Seattle made substantial gains in many lines despite the effects of the financial crash of 1929 and a period of labor strife in the 1930's. World War II brought a tremendous upsurge in her war industries—shipbuilding, airplane construction, and production of many war materials. As a port of embarkation, vast numbers of men and quantities of material moved across her waterfront and crowded her port facilities. The rapid increase in population and industrial activity did not halt with the conclusion of hostilities, however, but continued after the turn of the half-century.

HAROLD OTHO STONE.

SEAWEEDS, the simpler kinds of plants which grow in the water. The term is restricted to the lower plants, and does not include the aquatic kinds of mosses, liverworts, fernworts, and flowering plants (see ALGAE). Originally the term was applied exclusively to the plants which live in the seas and oceans, but these are now called "marine seaweeds" to distinguish them from the "fresh-water seaweeds" which grow in rivers, lakes, and ponds. The simplest of all plants, the blue-green slimes (*Cyanophyceae*) are the lowest of the seaweeds. They occur mostly in fresh waters; some, however, are marine. The green seaweeds (*Chlorophyceae*) are of considerably higher organization, the cells being distinctly nucleolated and possessing well defined chromatophores in which the green coloring matter resides. They include such single-celled types as the common green slimes (*Protococcus*), desmids, diatoms, the filamentous pondscums, green felts (*Vaucheria*), as well as some larger leaf-like and massive kinds (*Ulva, Caulerpa, Codium,* etc.). They occur abundantly in both fresh and salt waters throughout the world.

The brown seaweeds (*Phaeophyceae*) are closely related to the green seaweeds, and differ from them mainly in having an additional brown coloring matter which hides the green color of the chromatophores. The simplest forms are minute few-celled plants; others are branching filaments; while still others are large, massive plants many feet in length, and composed of root, stem and leaves. In all forms the mode of reproduction is of a simple type, showing their low grade in spite of the great size of some of the species. Among the larger plants of this group are the kelps (*Macrocystis, Lessonia,* etc.), devil's aprons (*Laminaria*) and rockweeds (*Fucus*). Some Pacific species of the first-named genus attain a length of several hundred feet, and are probably the longest plants in the world. Nearly all brown seaweeds are marine, a few only living in fresh waters. The red seaweeds (*Rhodophyceae*) are by far the most beautiful and interesting of aquatic plants. They are of a higher organization than those of the preceding groups. A few are composed of simple slender filaments, but they are more commonly multicellular stems, with roots below, and leaf-like or finely divided branches above. Although they are green plants, having well-developed chromatophores in their cells, they have in addition a reddish or purplish coloring matter which hides the green color. This often gives them a beautiful color which, added to their delicate and regular branches, makes them exceedingly attractive objects of study. They are commonly collected by seaside visitors, under the name of "seamosses." A few species live in fresh waters, all the others being marine. Some species are edible, as notably the so-called "Irish moss" (*Chondrus crispus*), of the Atlantic coast of America and Europe, from which is made the delicacy known as *blanc mange.* The highest of the seaweeds are the stoneworts (*Characeae*), which resemble some of the red seaweeds, but are of a green color, the red coloring matter not being developed in them.

SEAWELL, sē'wĕl, **Molly Elliot,** American novelist and playwright: b. Gloucester County, Va., about 1868; d. Washington, D.C., Nov. 15, 1916. After the death of her father, a nephew of President Tyler, Miss Seawell and her mother removed to Washington, D.C., where she began writing stories and sketches in 1886. Her first signed story was *Maid Marian,* which was subsequently dramatized. The next offering of Miss Seawell was *Throckmorton* (1890). It met with success as did *Children of Destiny,* which followed it in 1893. A prize of $500 offered by the *Youth's Companion* for a study of boys presented a new field for conquest. She won the prize over 3,000 competitors with *Little Jarvis.* So great was the popularity of the story that it was made the first of a series entitled *Young Heroes of Our Navy.* The succeeding volumes—*Decatur and Somers, Midshipman Paulding,* and *Paul Jones* were written by Miss Seawell, and maintained the success won by the first. In 1895 her *Sprightly Romance of Marsac* won a prize of $3,000 offered by the New York *Herald* for the best novelette. In 1900 she dramatized the story. In 1908 she won another *Herald* prize for a short story with *John Mainwaring, Financier.* Miss Seawell's other stories include *Twelve Naval Captains; The Rock of the Lion; The Imprisoned Midshipman; The Lost Duchess of Belgrade; The Secret of Toni; The House of Egremont; Papa Bouchard; Garvin Hamilton; A*

Strange, Sad Comedy'; 'The Victory'; 'The Chateau of Monplaisir'; 'The Marriage of Theodora'; 'A Virginia Cavalier'; 'The Jugglers'; 'The Lover of the Lady Arabella'; 'History of the Lady Betty Stair'; 'Francezka'; 'Fifi'; 'The Ladies' Battle,' and 'The Diary of a Beauty.' Miss Seawell was identified prominently with the anti-suffragist movement in Washington.

SEBACEOUS GLANDS, small structures of glandular nature and sacculated form which exist in the substance of the corium, or deep layer of the dermis or true skin. They are very generally distributed over the entire skin-surface, but are most numerous in the face and scalp. Those of the nose are of large size, and may frequently become enlarged from the accumulated secretion of the glands; while the largest in the body are the sebaceous glands of the eyelids, the Meibomian glands (see Eye). Around the orifices of the mouth and anus, nose and external ear, these glands are found in numerous array; but they appear to be absent from the skin of the palms of the hands and soles of the feet. Each sebaceous gland consists essentially of a lobulated or sac-like structure opening by a single efferent duct. The wall of the sac, as well as that of the duct, is lined by cells of cubical epithelium. These cells secrete the sebaceous matter which is chiefly fat, which collects in the gland, the cells becoming transformed into the secretion and breaking down in the process. The separate sacculi, or little pouch-like divisions which make up each gland, may vary in number from 2 or 5 to 20. As a general rule the ducts of the sebaceous glands open into the hair-follicles, or sac-like involutions of the skin which surround and enclose the roots of hairs. But in many cases the ducts open simply on the external surface of the skin. There are generally two sebaceous glands in connection with each hair. A curious little parasitic mite, harmless in its nature — the *Demodex folliculorum* — is frequently found inhabiting the sebaceous ducts of the nose, especially when their secretion is pent up. This little organism is not known to occur elsewhere.

The sebaceous glands are first developed in the sixth month of embryonic life, and appear in their earliest condition as sac-like appendages to the hair-follicles. The secreting cells, containing fat particles, appear in the centre of the developing gland; these cells gradually enlarge and, escaping by the root or attached portion of the sac, constitute the first secretion of the gland. The functions of the sebaceous secretion are chiefly those of keeping the skin moist and from being cracked by the influence of heat and of the air. Friction between skin surfaces is also diminished in the same manner by the sebaceous secretion. The secretion is present in greatest amount in those races which inhabit warm climates and are greatly exposed to the sun's heat. Pimples and boils are the most frequent types of inflammation of the sebaceous glands. See Hair; Skin.

SEBAGO (sĕ-bā'gō) **SALMON,** the land-locked salmon of Sebago Lake, Maine, and a few neighboring inland waters, which has lately been widely distributed through fish-cultural operations. It was long regarded as a mere land-locked variety of the Atlantic salmon, but Jordan and Evermann consider it entitled to rank as a species (*Salmo sebago*) distinct from that and from the Ouananiche (q.v.). In Sebago Lake it averages about 10 pounds in weight. Its habits are like those of the typical species with such modifications as the physical differences between the ocean and lake make necessary. «In Sebago Lake in the fall, structural and chromatic changes occur, and it ascends tributary streams to spawn. After this function is performed it returns to the lake, which is its ocean, and resorts to deep water. In the spring as soon as the ice breaks up, when smelts, upon which it extensively feeds, are running up the streams to spawn, the salmon follow them.» Consult Jordan and Evermann, 'Food and Game Fishes' (New York 1903), and American angling authorities generally.

SEBASTIAN, sĕ-băs'tĭ-ạn, **Saint,** a saint of the Roman Catholic calendar: b. Narbonne, Gaul, toward the middle of the 3d century; d. Rome, 20 Jan. 288. His position as captain in the Prætorian Guard at Rome gave him many opportunities of spreading Christianity, and protecting its adherents; but he was finally arrested and carried before Diocletian. The emperor ordered him to be shot to death by archers. A Christian woman named Irene, finding him still alive, drew out the arrows, took him home, and nursed him till he recovered. He then presented himself before Diocletian, and remonstrated with him for his cruelty; whereupon the emperor ordered him to be beaten to death, and his body to be thrown into the common sewer, whence it was taken by another Christian woman, called Lucina, who buried it at the feet of the apostles, Peter and Paul. In the 9th century his relics were carried to Soissons, whence they were dispersed through France, Spain, Germany and the Netherlands. A church was erected to this saint by Pope Damasus. Saint Sebastian is invoked against the plague, and is considered the patron saint of marksmen. His day is the 20th of January. There are many pictures of this saint by the Italian and other painters. He is generally represented as a beautiful youth tied to a tree and transfixed by arrows. The most famous pictures of his martyrdom are those by Luini, Bassi, Mantegna, Holbein, Paul Veronese and Ribera. In the cathedral at Lucca the subject has been treated in sculpture by M. Civitali.

SEBASTIAN, Dom, king of Portugal: b. 1554, d. 1578. He was the posthumous son of the Infant John by Joanna, daughter of Charles V, and ascended the throne in 1557, at the death of his grandfather, John III. During his minority the government was conducted by his great uncle, Cardinal Henry, brother of Emanuel the Great. He was educated by his guardian, Catharine of Austria, wife of John III (sister of Charles V). He was imbued with religious enthusiasm and a chivalrous desire to undertake a crusade. His constant dream was the conversion of Asia and Africa to Christianity, and the subjection of these continents to Portugal. At 20 he made an expedition to Ceuta, Tangier and Magazar, the only possessions that remained to the Portuguese from former conquests in Africa. From these places he suddenly fell upon the unsuspecting inhabitants and although no material results ensued, his lust for conquest became more con-

firmed. Soon afterward (1578) a war of succession broke out in the kingdom of Fez and Morocco. Mulei Malek, the youngest son of the last emir, had, contrary to his father's will, been excluded from the throne, but with foreign aid had finally succeeded in conquering his hereditary kingdom, and compelling his nephew, Mulei Mohammed, who had usurped it, to flee. The latter sought aid from Sebastian, who yielded to the request, hoping to effect something for Christianity and the fame of Portugal. In spite of the admonitions of his counselors, he equipped a fleet and an army, part of which he had collected in Spain, Germany and Italy, and sailed for Africa, 24 June 1578. The expedition reached Tangier in safety, but at Alcazarquivir was met by the far more numerous host of Mulei. Here on 4 Aug. 1578, a decisive battle was fought, in which Sebastian was completely defeated. Almost all his followers, including the best of his nobility, were either slain or taken prisoners, and he himself was among the missing. A corpse supposed to be the king's was found, but it was disfigured with so many wounds that identification was impossible. His death in consequence remained doubtful and gave occasion to the rise of several pretenders, the most notable of whom appeared in Venice 20 years afterward, and, after various vicissitudes, succeeded in arousing the sympathy of all Europe. Faith in his pretensions eventually subsided and he lapsed into obscurity. Consult D'Antas, Miguel, 'Les faux Don Sebastien' (1865).

SEBASTIANO DEL PIOMBO, sā-bäs-tē-ä'nō dĕl pē-ŏm'bō. See PIOMBO, SEBASTIANO DEL.

SEBASTOPOL, sē-băs'tō-pōl or sĕb-ăs-tō'-pōl, or **SEVASTOPOL** (Russ. sā-väs-tō'pol), an important seaport in the southeast portion of the autonomous Soviet Republic of Crimea, on a harbor famed for its excellence — an inlet of the Black Sea, four and one-half miles long, one-half mile wide at the mouth and one mile wide further inland, afterward averaging one-half mile across. Depth from three to 11 fathoms. It is enclosed by high limestone ridges, and is accessible to the largest ships. The river Tchernaya enters the harbor at the east. The principal part of the town occupies a slope between South Bay or Dockyard Harbor, and Quarantine Bay. Prior to the destruction of the town (1854–55) it was solidly built; the forts were marvelous strongholds mounted by 700 guns and the docks were among its most important works. The dock basin was supplied with water by a canal from the Tchernaya. The town was almost unprotected on the interior side, however, but the temporary defenses erected by General Todleben, during the Crimean War (the most formidable of which were the works of Malakoff and Redan) have since that time become celebrated. These works were, however, at last captured, at the end of a memorable siege by the allied French and English forces, the Russians retiring after the town had been ruined. The French and English engineers then blew up the docks and forts, which, by the Paris treaty (1856), were not to be rebuilt. These restrictions were annulled in 1871 by the London conference. The docks and forts were restored by the Russian government in 1885, and Sebastopol is now again the naval port for the Black Sea fleet. The town was bombarded by the Turks in the great European War. The town has been partially rebuilt — it was once an important commercial port, but Kaffa (q.v.) has taken its place since 1899, in this regard. The value of imports entering this port was formerly over $5,000,000; of exports, $15,000,000. Sebastopol was founded on the site of Akhtiar in 1783, by Catharine II. Many historical reminiscences render this an interesting spot. The promontory where the town now stands was once occupied by the temple where Iphigenia, daughter of Agamemnon, officiated as priestess. Later, Greeks colonized the promontory, but were overcome by the Genoese, who established themselves at Balaclava. The ruins of the Genoese castles are still to be seen. Pop. about 77,000.

SEBILLOT, sā-bē-yō, **Paul,** French folklorist: b. Matignon, France, 6 Feb. 1846. He was educated at the communal college of Dinan, studied law at Rennes, and established himself in Paris as a notary, but soon abandoned the law for art. From 1870–83 he exhibited about 20 pictures at the Salon, but his travels through Saint-Brieuc, Pont-Aven, and various out-of-the-way sections of Brittany aroused an interest in folklore, and he gradually drifted from art to the study of folklore, on which he wrote a series of excellent books. He succeeded to Henri Martin's seat in the commission for Megalithic Monuments, became *chef du cabinet* at the ministry of public works, and in 1889 chevalier of the Legion of Honor. From its foundation in 1885 he was editor of the *Revues des traditions populaires.* His works include 'Contes populaires de la Haute-Bretagne' (3 series, 1880–81–82); 'Légendes, croyances, et superstitions de la mer' (2 vols., 1886–87); 'Litterature orale de l'Auvergne' (1898); 'Le folklore des pechêurs' (1901); 'La mer fleurio le rivage Marius et corsaires' (1903); 'Le folklore de France' (1904–07); 'Le folklore, litterature orale et ethnographie traditionelle' (1913). He died in 1918.

SEBORUCCO, a narrow bench of coral rock margining a large part of the coast of Cuba. It is mostly a few yards wide and elevated about 15 feet above the sea. It is due to fringing coral reef raised by a general uplift of the island.

SECALE, *in botany,* rye, a genus of the *Triandria Digynia* class and order, in the natural order of *Gramineae* or grasses. Essential character, calyx opposite, two-valved, two-flowered, solitary. There are four species; the villosum, orientale, creticum and cereale. Secale villosum or wood-rye grass is distinguished by a calyx with wedge-shaped scales, and by the fringe of the glume being woolly. The glumes of the secale orientale are shaggy and the scales of the calyx are shaped like an awl. The glumes of the secale creticum are fringed on the outside. The secale cereale or common rye has glumes with rough fringes. There are two varieties, winter and spring rye. The winter rye, which is larger in the grain than the spring rye, is sown in the autumn, at the same time with wheat, and sometimes mixed with it; but as the rye ripens sooner than the wheat, this method is exceptionable. The spring rye is sown along with oats, and usually ripens as soon as the

winter rye; but the grain produced is lighter and it is therefore seldom sown. See RYE.

SECAUCUS, town, New Jersey, in Hudson County; altitude 41 feet; 3 miles northwest of Jersey City; on the Erie and Lackawanna railroads. There is truck farming in the surrounding area. The city's manufactures include clothing, silk, metal products, cleansers, and fertilizers.

The town was incorporated in 1917 and the government is administered by a mayor and council. Pop. (1950) 9,750.

SECCHI, sĕk'kē, **Angelo**, Italian astronomer: b. Reggio, Emilia, June 18, 1818; d. Rome, Feb. 26, 1878. He entered the order of the Jesuits in 1833, and after teaching in various Jesuit colleges, including Georgetown University, Washington, D.C., he was in 1849 appointed professor of astronomy and director of the observatory at the Collegio Romano. When the Jesuits were expelled from Italy in 1870 he was permitted to retain his position. Father Secchi made a careful study of the physical constitution of the sun, the nature of sun-spots, and the solar prominences, but of much greater importance was his pioneer work, carried out with less perfect instruments, contemporaneously with that of Huggins in stellar spectroscopy or astrophysics. He made the first systematic spectroscopic survey of the heavens and proposed a classification of stellar spectra under four main types, which has proved a valuable basis for subsequent research. Among his works are *Catalogo delle Stelle di cui si è determinato lo Spettro luminoso* (1867); *L'Unità delle Forze fisiche* (1869); *Le Soleil* (1870); *Le Stelle* (1877).

SECESSION, the act of withdrawing from, a term of great political importance, especially in the history of the United States. Whenever a state has claimed the right to withdraw from the Union, it has based its claim on the doctrine of state sovereignty. This claim must be considered as emphatically distinct from the right of revolution, insurrection or violent revolts, in all of which there is no claim technically of legal right, and the appeal of which is to force instead of reason. Nearly every state of the Union, in its turn, has advanced the right of secession and usually each has ben condemned by the others as treasonable. This claim was specifically brought forward or involved in the "Kentucky Resolutions," the "Hartford Convention" (qq.v.) and the "Nullification Ordinance." The election of Abraham Lincoln to the presidency of the United States in 1860, when the political situation was flanked with sectional differences resting on state claims, was all that was necessary to change the theory of secession in the South into an attempt to effect the reality. South Carolina took the lead. No single state was prepared or willing to secede alone, but Florida, Mississippi, and Alabama agreed to secede with any other state. Again South Carolina was leader in calling a state convention, and on Dec. 20, 1860 the Act of 1788, ratifying the national Constitution, was repealed, and it was declared "that the union now subsisting between South Carolina and other States, under the name of the United States of America, is hereby dissolved." A declaration of the causes for this act was formulated and was adopted on the 24th. The governor proclaimed "the secession of South Carolina" the same day. Mississippi was the first to follow this example, on Jan. 9. 1861; then in succession came Florida, on January 10; Alabama, January 11; Georgia, January 19; Louisiana, January 26; and Texas, February 1, though in the case of this last state the proceedings were irregular. Virginia followed in April; Arkansas and North Carolina in May and Tennessee in June. The Civil War was the consequence; its final issue was the victory of the Union government in 1865 and the reincorporation of the seceding states in the United States. See also SECESSION IN THE UNITED STATES; UNITED STATES—*Causes of the Civil War; Secession.*

SECESSION CHURCH, in Scottish ecclesiastical history, a religious body which withdrew from the Established Church of Scotland in 1733, when several preachers were ejected in consequence of their opposition to the law of patronage. The ejected ministers formed themselves into an ecclesiastical court, under the name of the "Associated Presbytery," and published an act, declaration and testimony to the doctrine, worship, government and discipline of the Church of Scotland. In 1747 a division arose among the seceders respecting the legality of the burgess oath, in which burgesses profess "the true religion professed within the realm." Those who asserted the lawfulness of the oath were called burghers, those who condemned it anti-burghers. In 1820 they were reunited as "The Associated Synod of the Secession Church," several congregations of each party, however, refusing to accede to it. In 1847 the Associated Synod, joining with the Relief, constituted the United Presbyterian Church. See PRESBYTERIANISM; SCOTLAND.

SECESSION IN THE UNITED STATES. To properly understand the causes which led to the secession of the Southern States in 1861 and the reasons which actuated those by whom such action was advocated, we must confine our investigations to the history of the country and the conditions which existed prior to the dates when the seceding states withdrew from the Union. If we look back from the standpoint of today, we see but little of the picture which was presented at that period. We must study the theory of the Constitution as understood and explained by its creators, and the history of the period prior to 1861, at least so far as it relates to constitutional rights and construction. It will also be interesting to consider the views entertained by advocates of the states' rights doctrine as distinguished from the views of the extreme nationalists, and we must also become informed regarding the long-continued struggle between the leaders of these two parties. In 1860 not only the leaders but the Southern people generally were firm in the belief that a state had the legal right to secede from the federal Union. This was the natural result of the teachings of more than half a century. Whatever opposition existed in the several state conventions or among the people of the seceding states arose not on the question of the principle of secession, the right to secede, but upon the expediency of seceding. Perhaps the most conspicuous example of the unity of the people of the seceding states is to be found in the proceedings of the Alabama Convention. A very large minority of this convention, for a while supposed to be a majority, was elected on the following platform: "That we hold it

to be our duty, *first,* to use all honorable exertions to *secure* our rights *in* the Union, and if we should fail in this, we *will maintain* our rights *out of the Union;* for, as citizens of Alabama, we owe our allegiance first to the State; and we will support her in whatever course she may adopt."

With rare exceptions the arguments against such action were on the ground that it was inexpedient and inadvisable, but when the act was consummated it was generally recognized in the seceded States as the supreme law of the land, the exceptions being for the most part confined to a few counties in East Tennessee and the sparsely inhabited strip of mountain land known as the southwestern part of the Alleghanies. In this connection it is important to state that in 1861 and for years prior to that time this belief in the right of secession was by no means confined to the South, or to the so-called pro-slavery party. Horace Greeley, editor of the New York *Tribune,* was outspoken in upholding the right of secession, and for months after the establishment of the Confederate government army officers from the South openly discussed the question of remaining in the Union army or joining the Confederacy, and those who decided upon the latter course were allowed to go freely.

General Joseph E. Johnston and Col. Robert E. Lee both continued in the performance of their army duties in Washington for nearly two months after the inauguration of President Lincoln, the former holding the all-important position of quartermaster-general of the army of the United States; and it was after it was generally known that Colonel, afterward General, Lee had decided that it was his duty to give his fealty to his native State, Virginia, that Mr. Lincoln offered him the appointment as commander-in-chief of all the armies of the United States. At that time the authorities in Washington did not use the words treason and traitors in referring to the Southern officers who resigned their commissions and joined the Confederate army. But the results of the appeal to arms whereby the advocates of secession were overwhelmed have clouded and caused to be utterly forgotten the legal and logical principles for which the States Rights party had contended for three-quarters of a century.

Greeley said in 1860: "War is a hideous necessity at best, and a civil conflict, a war of estranged and embittered fellow countrymen, is the most hideous of all wars." (New York *Tribune,* 16 Nov. 1860). And his words were prophetic. In the terrible internecine war of four years more than 1,000,000 human beings, most of whom were the youth of the land, fell in battle or succumbed to disease and the hardships of campaign, or were wounded and maimed; while in nearly every home, North and South, heartbroken mourners were crushed by the awful sacrifice to the God of Battles. During and at the close of the war every branch of the government was under the control of those responsible for the coercive policy which brought it on. With rare exceptions the whole press of the Northern States and its literature were dominated by the same influences. The chief executive and all his subordinates in the government with one acclaim pronounced the edict that those who had not supported their views should be made odious to the American people, and from that time the teaching to the youth of the land has been of this character. The causes which influenced the action of those who brought about the secession of the Southern States became utterly obscured and forgotten.

Causes of Secession.— The general assumption that slavery was the sole cause of secession and the war that followed is very far from correct. It is clearly to be seen that far away and beyond the question of slavery, even in the very earliest days of the life of the nation, the two parties began the struggle — the one to maintain the unrelinquished rights of the States, the other to establish and vest greater power in the central government. But although this leading question, and other cognate questions were really at issue in this conflict, slavery was the proximate occasion of the Civil War. The anti-slavery agitation focused and brought into active operation the theories of the extreme nationalists that the central government had the right to go into the domain of State governments and regulate their domestic affairs. And the threats of the abolitionists awoke the Southern people to the realization that the guarantees of the Constitution for the protection of slave property were to be nullified and, at least to that extent, the rights of the States destroyed. It is, therefore, necessary to review the history of this contributing, if not paramount, cause, without entering upon any discussion of the question of slavery itself.

History of Slavery.— Slavery was not only a heritage from the mother country, but the history of early colonial times shows that it was a forced heritage that was resisted and opposed by the colonies. In the same spirit the Southern people opposed slavery at the time of the Declaration of Independence and were vigorous in resisting the further importation of slaves from Africa. The wise men of that day foresaw the evils attending such a traffic. Its enormous profits would cause a further great influx of people hardly removed from savagery. But when slavery became a fixed institution, recognized, guaranteed and protected by the Constitution, the people of the South sought to ameliorate, so far as possible, all the evils attending it. Slavery was part of the common law of England prior to the settlement of the first colonies in America, and became the common law of the colonies; and at the time of the Declaration of Independence existed in each of the 13 colonies. As above stated, this condition existed despite the efforts of some of the colonies to terminate it. Judge Cooley in his continuation of Story's 'Commentaries on the Constitution,' says: "No colony was so persistent in its efforts to check the [slave] trade as Virginia, and Judge Tucker enumerates 23 acts on the subject, beginning with 1699." Georgia, under Oglethorpe, prohibited the importation of slaves until 1752, when the proprietors surrendered the charter and the colony became part of the royal government, when the power of the colonists to prevent the importation of slaves ceased, the Crown prohibiting the exercise of any such power by the colonists. In 1760 South Carolina passed an act prohibiting the further importation of African slaves. The act was rejected by the Crown; the governor was reprimanded; and a circular was sent to all the governors of the

colonies warning them against presuming to countenance such legislation.

England not only considered the slave trade beneficial, and fostered and protected it, but had actually inaugurated and established it. Its first appearance in history is in the grant of a charter by Queen Elizabeth to a company formed to supply African slaves to the Spanish-American colonies — the queen herself being a shareholder in the company. In 9th and 10th William III an act was passed reciting that «the trade was highly beneficial and advantageous to the kingdom.» In 1708 the House of Commons resolved: «That the trade was important, and ought to be free and open to all the queen's subjects trading from Great Britain.» And as late as 1775 the Earl of Dartmouth, in answer to a remonstrance from the agent of the colonies, said: «We cannot allow the colonies to check or discourage in any degree a traffic so beneficial to the nation.» And so popular was this traffic that slaves were openly sold in the public squares of London. Thus were the efforts of the colonies, led by Virginia, Georgia, Maryland and South Carolina, to put an end to the traffic, thwarted by the greed of the traders in the mother country.

The first African slaves imported into America were landed by a Dutch trading vessel at Jamestown in 1620, and from that time the traffic became general throughout all the colonies Pecuniary profit to the traders and the need of the negro as a laborer was not the only incentive to this traffic. The press and even the pulpit contended that it was humane and Christian to bring these heathen savage negroes to the protective care of civilized people. Slaves were imported in large numbers into New England until it became apparent that they were not fitted to the rigorous climate of the North. Importation to the northern colonies and States gradually diminished and finally ceased, but New England shipowners continued for many years to be actively engaged in the business of importing and selling slaves. Notwithstanding the reasons in favor of this business the leaders of thought among the Southern colonists continued to fight against the traffic, and Jefferson, in his first draft of the Declaration of Independence, brought forth, as one of the counts in his indictment of the king, «this cruel war against human nature itself . . . this piratical warfare,» and charged that the king had «prostituted his negative for suppressing every legislative attempt to prohibit or to restrain this execrable commerce» in order to keep open a market for the sale of human beings. Jefferson gave, among other reasons for omitting this clause from the final draft of the Declaration: «Our Northern brethren also, I believe, felt a little tender under those censures; for, although their people had very few slaves, yet they had been pretty considerable carriers of them to others.» This traffic against which the colonies had waged war for a century continued to exist at the time of the Declaration of Independence; and when the Constitution was adopted slavery existed in every colony with the possible exception of Massachusetts, where in 1781, not by legislative enactment, but by a decision of the Supreme Court of that colony, it was declared inconsistent with the declaration of the Bill of Rights that «all men are born free and equal.»

The framers of the Constitution (q.v.) realized the sensitive and delicate nature of the question of slavery, and wisely left it untouched except to protect the property rights of the slaveholders and to give to Congress the power to prohibit the importation of slaves after a certain date. The third paragraph of section 2 of Article IV of the Constitution provided that «no person held to service or labor in one State, under the laws thereof, escaping into another, shall, in consequence of any law or regulation therein, be discharged from such service or labor, but shall be delivered upon claim of the party to whom such service or labor may be due.» Under this clause Congress passed the Fugitive Slave Law (q.v.) of 1793. The first paragraph of section 9 of Article I of the Constitution provided: «The migration or importation of such persons as any of the States now existing shall think proper to admit shall not be prohibited by Congress prior to the year one thousand eight hundred and eight, but a tax or duty may be imposed on such importation, not exceeding ten dollars for each person.»

The history of the adoption of this clause sheds much light upon the attitude of the Southern slaveholders. The first draft provided: «No tax or duty shall be laid, etc., on the migration or importation of such persons as the several States shall think proper to admit; nor shall such migration or importation be prohibited.» South Carolina and Georgia insisted that the freedom of importation should be limited, and insisted upon a limitation as a condition of the Union; and the clause limiting until 1808 the prohibition against Congress of preventing such importation was finally adopted.

During the period from 1787 to 1808 the question of prohibiting the importation of slaves was entirely under the control of the States, and every Southern State which had not already done so enacted laws prohibiting further importation of slaves. Jefferson's earnestness in opposing the traffic has already been noticed, and Virginia was the first State to prohibit it. Georgia was the first State to incorporate such a prohibition in the Constitution. Henry Laurens of South Carolina writing to his son, 14 Aug. 1776, said: «You know, my dear son, I abhor slavery. I was born in a country where slavery had been established by British kings and parliaments, as by the laws of that country, ages before my existence. . . . Not less than 20,000 pounds sterling, would all my negroes produce, if sold at public auction to-morrow. I am not the man who enslaved them; they are indebted to Englishmen for that favor; nevertheless I am advising means for manumitting many of them, and for cutting off the entail of slavery. . . . I perceive the work before me is great.»

Mr. Lowndes of South Carolina, speaking in the House of Representatives on 14 Feb. 1804, of the impossibility of prohibiting the importation of slaves into his State, said: «With navigable rivers running into the heart of it, it was impossible for us, with our means, to prevent our eastern brethren from introducing them (the negroes) into the country. The law was completely evaded.»

In 1807 Congress passed an act prohibiting the importation of slaves into any part of the United States after 1 Jan. 1808. The vote in

the House of Representatives was almost unanimous, being 113 against 5. Of the five who voted against it only three were from the South, one being from the Portsmouth district, New Hampshire, and one from Vermont. Mr. Betton from New Hampshire represented large shipping interests; and that the vote of Mr. Crittenden of Vermont was approved by the people of his State is shown by the fact that he was three times re-elected to Congress, and was subsequently elected governor and judge. This vote shows the absence of any sectional division of sentiment on the subject. In the meantime in 1784 Virginia had ceded to the United States the great Northwest Territory, and in 1787, before the adoption of the Constitution, the Congress had adopted the Ordinance for the Government of the Northwest Territory. This was adopted at the instance of Virginia, and its Sixth Article provided that "there shall be neither slavery nor involuntary servitude in the said Territory, otherwise than in punishment of crimes whereof the party shall have been duly convicted." In December 1805 the legislative council and house of representatives of the Indian Territory petitioned Congress to suspend the operation of the Sixth Article, and petitions of numerous inhabitants of the Territory, together with a letter of William Henry Harrison, governor of the Territory, of the same purport, were forwarded to Congress. These petitions were referred to a committee of seven members consisting of representatives from Virginia, Pennsylvania, Ohio, New York, Kentucky and South Carolina, who reported favorably to the petition, but no final action was taken by Congress. In January 1807 a letter from Governor Harrison enclosing resolutions unanimously adopted by the legislative council and house of representatives of Indiana, petitioning for the suspension of the Sixth Article and for the introduction of slavery, was laid before Congress. The matter was again referred to a committee whose members were drawn from various sections of the country. The committee again reported favorably, the House adopted a resolution suspending the article, but the Senate failed to concur in it and the matter was dropped.

Although the importation of slaves was prohibited the institution of slavery became more firmly intrenched in the slave-holding States, and at the same time a sentiment in favor of its abolition grew stronger in the non-slaveholding States. In 1819 a violent dispute arose between the North and South, the occasion being the proposal to admit Missouri as a State. After a year of bitter controversy a settlement was reached in a compromise whereby Missouri, with a constitution permitting slavery, was admitted, but as to the remaining portion of the territory of the United States lying north of lat. 36° 30′ N., it was provided that slavery should be prohibited. In the North the compromise was exceedingly unpopular, and a general movement looking toward the abolition of slavery was commenced. In 1840 and in 1844 the anti-slavery party had Presidential candidates in the field. The annexation of Texas, the war with Mexico and the further acquisition of territory furnished cause for additional controversy. In 1848 the anti-slavery party showed growing strength, and political campaigns took on increasing bitterness. The one side depended upon the guarantees of the Constitution to protect its property rights; the other insisted upon their right to prevent the extension of slavery, "while conceding," as Judge Cooley admits, "that the Federal government was powerless to disturb it in the States." During these times of fierce controversy the greatest minds from all sections of the country devoted their efforts to securing peace. Clay, Webster, Cass and Benton met in harmony and by their united efforts secured the compromise of 1850 by which California was admitted as a free State, new States were to be permitted to be carved out of Texas, the slave trade was prohibited in the District of Columbia and new Territories were to be organized without either expressly permitting or prohibiting slavery. But these compromises and all the efforts of the peacemakers were futile. The Missouri Compromise was repealed, the Fugitive Slave Law was nullified in the North, in Kansas armed conflicts occurred between the opposing factions, and in October 1859 John Brown with a band of Northerners made a raid into Virginia in an endeavor to incite the negroes of the South into insurrection, rapine and bloodshed.

The almost unanimous sentiment, North and South, upon the question of re-opening the African slave trade is shown by the vote on the following resolution introduced in the House of Representatives by Mr. Orr of South Carolina, on 15 Dec. 1856: "Resolved, That it is inexpedient, unwise and contrary to the settled policy of the United States, to repeal the laws prohibiting the African slave trade." This resolution was adopted by a vote of 183 to 8, and most of those voting against it explained their votes by stating that no proposition looking to the opening of the slave trade having been presented the resolution was out of place. In 1856 the anti-slavery party had made great progress and came near electing their candidate for President. It was hoped that the decision of the Supreme Court in the Dred Scott case (q.v.) would put an end to the political agitation, but the decision being adverse to the theories of the abolitionists added fuel to the flame. The Supreme Court and the venerable chief justice became objects of the most venomous abuse. In the controversy which now raged, moderation and reason seemed annihilated in the bitterness of feeling. The ablest minds of the North were exercised in constructing arguments to justify the coercive policy. Floods of anti-slavery literature were poured out before the impressionable youth. The pulpit and the lecture hall rang with appeals in which slander and denunciation were the key-notes, and the press took up and echoed their appeals.

While many people in the North were actuated solely by the belief that slavery was a wrong that should be abolished yet it was not until the question became one of national and political importance that the party opposed to the one in power used it as a means to secure control of the government. Like all other questions which become political, misrepresentations of the grossest character were made in order to attain political ends. Therefore, the pictures of slavery as presented to the Northern mind were in marked contrast to actual conditions as seen by those who were surrounded by them. It is true that there were

exceptional cases where there was apparent cruelty, and some cases where the slaves endured real hardships; and these cases were almost exclusively confined to the Mississippi and other alluvial bottom lands where the slaves were removed from the care and protection of their masters and were controlled by overseers, whose sole effort was each year to attain the highest financial results for their employers. But while the cases of hardship were few in number they were seized upon, colored and exaggerated in order to, so far as possible, inflame the Northern mind against the institution. The conditions as they appeared to the Southern people were, with rare exceptions, in marked contrast with the tales spread in the North. The planter of the South, or his ancestors, had seen the most degraded of human beings brought from Africa. Most of them had been, in their native land, slaves of tyrannical and cruel negro masters. They had become the property and in a certain sense members of humane, Christian families. The instincts of humanity and the interests of ownership had combined to lift these negro slaves from the lowest conditions of savagery into a state of civilization, where they were well fed, well clothed, protected and all their physical wants attended to, and furthermore where they were uplifted morally, surrounded by Christian influences and given Christian instruction. While slavery had its evils, history has record of no people who made so rapid an advance from a low condition of savagery and immorality to one of comparative civilization and moral responsibility as was shown by the improvement in the condition of the savage negroes that were brought to this country by the slave-traders. It has been charged that the Southern people took care of their slaves only because they were property and because the loss of a slave was a monetary loss. This charge is unjust in the extreme, and is in line with other calumnies which would deny all humanity to the slave-holding Southerners. The Southern people as a class cared well for their slaves, not only because they were property, but also because there was a real bond of affection between the master and the slave, and between all the members of the master's family and all the slaves in his house or on his plantation. Proof of the real conditions can be found in the following extract from Booker T. Washington's 'Up From Slavery':

> One may get the idea, from what I have said, that there was bitter feeling toward the white people on the part of my race, because of the fact that most of the white population was away fighting in a war which would result in keeping the negro in slavery if the South was successful.
>
> In the case of the slaves on our place this was not true, and it was not true of any large portion of the slave population in the South where the negro was treated with anything like decency. During the Civil War one of my young masters was killed, and two were severely wounded. I recall the feeling of sorrow which existed among the slaves when they heard of the death of "Marse Billy." It was no sham sorrow, but real. Some of the slaves had nursed "Marse Billy"; others had played with him when a child. "Marse Billy" had begged for mercy in the case of others when the overseer or master was thrashing them. The sorrow in the slave quarter was only second to that in the "big house." When the two young masters were brought home wounded, the sympathy of the slaves was shown in many ways. They were just as anxious to assist in the nursing as the family relatives of the wounded. Some of the slaves would even beg for the privilege of sitting up at night to nurse their wounded masters. This tenderness and sympathy on the part of those held in bondage was a result of their kindly and generous natures. In order to defend and protect the women and children who were left on the plantations when the white males went to war, the slaves would have laid down their lives. The slave who was selected to sleep in the "big house" during the absence of the males was considered to have the place of honour. Any one attempting to harm "young mistress" or "old mistress" during the night would have had to cross the dead body of the slave to do so. I do not know how many have noticed it, but I think that it will be found to be true that there are few instances, either in slavery or freedom, in which a member of my race has been known to betray a specific trust.
>
> As a rule, not only did the members of my race entertain no feelings of bitterness against the whites before and during the war, but there are many instances of negroes tenderly caring for their former masters and mistresses.

As a general rule (the exception being in the bottom lands where but few white people lived except the overseers, and where the worst and most untractable negroes were sent) the virtue of the negro women was carefully guarded by the slave-owners, and for several reasons. First, the Southern people were, as they are to-day, essentially religious and, as above stated, took great care of the moral training of the negroes. In most of the small establishments the mistress of the house assumed this as one of her duties, and on most of the large plantations where there were from 100 to 1,000 slaves, a chapel was provided and a minister employed to teach religion and morals. A plantation upon which there were no mulatto children was the more valuable, and conveyed an idea of commendation which attached to all who were connected with it. In the third place marriage and chastity among the slaves were fostered and promoted for property reasons. So far did the Southern people go in protecting the female slaves that regular patrols were organized for the purpose of arresting and punishing the lower class of white men who prowled around at night among the negro cabins. Of course the Southern people were greatly incensed by the gross misrepresentations as to their cruelty and immorality, and believed that the object of these misrepresentations was to arouse a sentiment which would lead to the attempt of the Northern people, acting through the national government, to interfere with the right of self-government guaranteed by the Constitution, and to deprive them of their property. And the feelings of resentment which naturally followed widened the breach day by day, month by month and year by year; until it became apparent that only a cessation of the agitation could prevent complete separation of the two sections. So that from the moment of the John Brown raid into Virginia the South saw the necessity of preparing to protect its rights and property — in the Union if possible — out of it if necessary. These were the conditions when, in 1860, the anti-slavery or Republican party elected its candidate, not so much by the strength in the North of its own following as by the division among the Democrats. By the vote which elected Mr. Lincoln the South was given to understand that the Constitution was to be disregarded and slavery destroyed, and so destroyed as to bring financial ruin, if not utter annihilation upon the South, for Wendell Phillips, a recognized leader, has said «The state of things is just what we have attempted to bring about. . . . The Republican party is a party of the North, pledged against the South.» And the Southern people turned to the remedy which for three-quarters of a century they had believed to be the legal and proper one for

denial of rights by the national government, namely, withdrawal from the Union — secession.

The Doctrine of Secession.— As stated from the foundation of the Federal government until 1861, and even at that date, the right of secession was insisted upon not only in the South but in the North. In fact New England had been the first to advocate and threaten it. To discover the basis of this doctrine the history of the Federal government must be briefly reviewed. The colonies were settled by the Cavaliers in Virginia, the Puritans in New England, the Hollanders in New York, the Catholics in Maryland, the Quakers in Pennsylvania, the Huguenots in South Carolina and the followers of Oglethorpe in Georgia. The colonists of New England whose descendants spread westward were very different in their ancestry, their education, their beliefs and their customs, from those who settled the South and whose descendants spread over the Southwest. Those of New England were largely the descendants of the Roundheads of England, and entertained ideas similar to theirs. Those of the South sprang from the Cavalier class of England and France. The colonial States when they renounced their allegiance to Great Britain were separate and distinct commonwealths, entirely independent of one another. The desire for complete independence was the claim that welded their union in their efforts to achieve their common end. The political union of these independent colonies was based solely upon the terms of agreement and compact entered into by these separate and distinct bodies. The first union of this character was that formed by the 13 colonies in 1774, which was followed by the union of the States under the Articles of Confederation of 1777 (Maryland being the last State to ratify them, in 1781). On 4 July 1776, the colonies declared "that they are and of right ought to be *Free and Independent States*" — "that whenever any form of government becomes destructive of the ends for which it was established, it is the right of the people to alter or abolish it, and to institute a new government." In the Articles of Confederation the States, while agreeing to clothe the Congress with the powers of a common agent, expressly stipulated "that each State retains its sovereignty, freedom and independence and every power and right which is not, by this Confederation, expressly delegated to the United States in Congress assembled." Great Britain in Article I of the treaty of 3 Sept. 1783, "acknowledges the said United States, namely" (mentioning each of the 13 States), "to be *Free, Sovereign* and *Independent States*." The confederation under the Articles of 1777 was succeeded by the Union under the Constitution adopted by the 12 States assembled in Constitutional Convention (Rhode Island holding aloof) and subsequently ratified by all the States. It is to be remembered that until North Carolina ratified the Constitution in November 1789, and Rhode Island ratified it in May 1790, these two States were considered as entirely independent commonwealths.

In the Constitutional Convention, and therefore until 1861, the Supreme Court of the United States and the highest courts of the several States maintained in their decisions the principle of the unrelinquished sovereignty of each State, all holding that the central government had no right to exercise any powers, except such as were expressly delegated, or Congress to enact any laws except in pursuance of an express right granted by the States through the Constitution. This doctrine was formally enunciated in the tenth amendment to the Constitution: "The powers not delegated to the United States by the Constitution, nor prohibited by it to the States, are reserved to the States respectively, or to the people." The question of coercion of a State was raised in the Constitutional Convention and was quickly disposed of. When a proposition was made to empower Congress "to call forth the force of the Union against any member (meaning State) of the Union failing to fulfill its duty under articles thereof" — Mr. Madison said that "a union of the States containing such an ingredient seemed to provide for its own destruction. The use of force against a State would look more like a declaration of war than an infliction of punishment and would probably be considered by the party attacked as a dissolution of all previous compacts by which it might be bound." He hoped "that such a system would be framed as might render this recourse unnecessary, and moved that the clause be postponed." Madison's motion prevailed unanimously. Every similar proposition was rejected. George Mason said of such a proposition: "Will not the citizens of the invaded State assist one another, until they rise as one man and shake off the Union altogether?" Oliver Ellsworth in speaking to the Connecticut Convention said: "This Constitution does not attempt to coerce sovereign bodies, States, in their political capacity." Alexander Hamilton said in the New York Ratifying Convention: "To coerce the States is one of the maddest projects that was ever devised." Edmund Randolph, one of the most advanced of the Federalists, said that coercion was out of the question. When the States ratified the Constitution they expressed in no uncertain terms their insistence that the State could not be coerced and could at any time withdraw from the confederation and retake the powers granted to the Federal government. New York and Rhode Island said that "the powers of government may be reassumed by the people whenever it shall become necessary to their happiness." Virginia in ratifying did "declare and make known that the powers granted under the Constitution being derived from the people of the United States, may be reassumed by them, whensoever the same shall be perverted to their injury or oppression, and that every power not granted thereby remains with them and at their will." The principle of the right of secession had always been sanctioned by the people of Massachusetts. When it was proposed to annex Louisiana to the Federal Union, the legislature of Massachusetts passed the following resolution: "That the annexation of Louisiana to the Union transcends the constitutional power of the government of the United States. It formed a new confederacy, to which the States united by the former compact *are not bound to adhere*." And in 1844 and again in 1845 the same legislature resolved: "That the project of the annexation of Texas, unless arrested on the threshold, *may drive* these States into a *dissolution of the Union*."

Alexander Hamilton was without question one of the most extreme advocates of a strong central national government, but even he ex-

pressed himself emphatically that any attempt on the part of Congress to enact a law which involved the exercise of power which was not granted by the Constitution would be an invasion of the power reserved to the States. He discussed this question in the 31st number of the *Federalist,* and concludes in these words: «Hence we perceive that the clause which declares the supremacy of the laws of the Union, like the one we have just considered, only declares a truth which flows immediately and necessarily from the institution of a Federal government. It will not, I presume, have escaped observation, that it expressly *confines this supremacy to the laws made pursuant to the Constitution.*» At the time of the adoption of the Constitution, during the period of ratification and for many years thereafter this principle was not questioned. It was so thoroughly recognized that so long as any members of the Constitutional Convention remained members of Congress, and for a long period thereafter, that body confined its acts to expressly granted powers; and the messages of the Executive to Congress were only explanations of the condition and state of the Union — so very different from the messages since 1865 which are largely devoted to proposed policies of the administration, and exact from the President's party loyal obedience thereto.

In 1839 John Quincy Adams in his speech on the occasion of the 50th anniversary of our government under the Constitution said:

But the indissoluble union between the several States of this confederated nation is, after all, not in the right but in the heart. If the day should ever come (may Heaven avert it) when the affections of the people of these States shall be alienated from each other; when the fraternal spirit shall give way to cold indifference, or collision of interest shall fester into hatred, the bonds of political asseveration will not long hold together parties no longer attracted by the magnetism of conciliated interests and kindly sympathies; and far better will it be for the people of the disunited States to part in friendship from each other than to be held together by constraint. Then will be the time for reverting to the precedents which occurred at the formation and adoption of the Constitution to form again a more perfect Union *by dissolving* that which can no longer bind, and *to leave the separated parts* to be reunited by the law of political gravitation to the centre.

That Mr. Adams felt that these views were consistent with a true interpretation of the original compact which bound the people together is shown by the fact that three years later, 24 Jan. 1842, he presented to Congress a secession petition from citizens of Haverhill, Mass. In the *Congressional Globe* (Vol. II, p. 977) appears the following:

Monday, January 24.— In the House Mr. Adams presented the petition of sundry citizens of Haverhill, in the State of Massachusetts, praying that Congress will immediately adopt measures, peaceably to dissolve the Union of these States: First, because no union can be agreeable or permanent which does not present prospects of reciprocal benefits; second, because a vast proportion of the revenues of one section of the Union is annually drained to sustain the views and course of another section, without any adequate return; third, because, judging from the history of past nations, that Union, if persisted in in the present state of things, will certainly overwhelm the whole nation in destruction.

On the question of the reception of the petition, there were 40 votes in favor of it and 166 against. The following resolution was then introduced: «Resolved: That in presenting to the consideration of this House a petition for the dissolution of the Union, the member from Massachusetts (Mr. Adams) has justly incurred the censure of this House.» Another resolution was introduced declaring that Mr. Adams had offered the deepest indignity to the House and an insult to the people of the United States In defending his position Mr. Adams said:

I hold that it is no perjury, that it is no high treason, but the exercise of a sacred right to offer such a petition, and that it is as false in morals as it is inhuman to fasten that charge on men who, under the countenance of such declarations as I have here quoted, come and ask this House a redress of grievances. And if they do mistake their remedy this government should not turn them away and charge them with high treason and subornation of perjury; but ought to take it up, to weigh the considerations which can be urged in their favor; and if there be none but those which are so eloquently set forth in the pamphlet I have quoted, these should be considered. If they have mistaken their remedy, the House should do as the gentleman from Kentucky (Mr. Marshall) told us he was ready to do — admit the facts.

«The trial of Mr. Adams, to the exclusion of all other business, commenced on 25 January, and terminated on 7 February, when the whole proceedings were laid on the table without deciding a single question.» This action of the House was construed by some as an admission that circumstances might arise which would justify States in withdrawing from the Union. Daniel Webster in his speech at Buffalo on 22 May 1851 denounced the anti-slavery agitators who were opposing the enforcement of the Fugitive Slave Law, and demanded that they should observe the laws and the Constitution. And a little later, at Capron Springs, he said:

How absurd it is to suppose that when different parties enter into a compact for certain purposes, either can disregard any one provision, and expect, nevertheless, the other to observe the rest. . . . I have not hesitated to say, and I repeat, that if the northern States refuse wilfully and deliberately to carry into effect that part of the Constitution which respects the restoration of fugitive slaves, and Congress provide no remedy, the South would no longer be bound to observe the compact. A bargain cannot be broken on one side and still bind on the other side. I say to you, gentlemen in Virginia, as I said on the shores of Lake Erie and in the city of Boston, as I may say again in that city or elsewhere in the North, that you of the South have as much right to receive your fugitive slaves as the North has to any of its rights and privileges of navigation and commerce. . . . I am as ready to fight and fall for the constitutional rights of Virginia as I am for those of Massachusetts.

Horace Greeley, the abolitionist, strongly insisted, in 1860, upon the right of the Southern States to secede, as the following extracts from the *Tribune* show:

New York *Tribune*, 9 Nov. 1860.— If the cotton States shall become satisfied that they can do better out of the Union than in it, we insist on letting them go in peace. The right to secede *may* be a revolutionary one, but it exists nevertheless.

And again in the same issue of his widely circulated and influential paper, Mr. Greeley said:

We must ever resist the asserted right of any State to remain in the Union and nullify or defy the laws thereof. To withdraw from the Union is quite another matter; and whenever a considerable section of our Union shall deliberately resolve to go out, we shall resist all coercive measures designed to keep it in.

New York *Tribune*, 16 Nov. 1860.— Still we say, in all earnestness and good faith, whenever a whole section of this republic, whether a half, a third, or only a fourth, shall truly desire and demand a separation from the residue, we shall earnestly favor such separation. If the fifteen slave States, or even the eight cotton States alone, shall quietly, decisively, say to the rest, "We prefer to be henceforth separated from you," we shall insist they be permitted to go in peace.

New York *Tribune*, 19 Nov. 1860.— Now we believe and maintain that the Union is to be preserved only so long as it is beneficial and satisfactory to all parties concerned. We do not believe that any man, any neighborhood, town, county, or even State may break up the Union in any transient gust of passion; we fully comprehend that secession is an extreme, an ultimate resort — not a constitutional but a revolutionary remedy. But we insist that

this Union shall not be held together by force whenever it shall have ceased to cohere by the mutual attraction of its parts; and whenever the slave States or the cotton States only shall unitedly and coolly say to the rest, "We want to get out of the Union," we shall urge that their request be acceded to.

New York *Tribune*, 30 Nov. 1860.— Are We Going to Fight? — But if the cotton States generally unite with her in seceding, we insist that they cannot be prevented, and that the attempt must not be made.

New York *Tribune*, 24 Dec. 1860.— Most certainly we believe that governments are made for the peoples, not peoples for the governments; that the latter derive their just power from the consent of the governed; and whenever a portion of this Union, large enough to form an independent self-sustaining nation, shall show that, and say authentically to the residue, "We want to get away from you," I shall say, and we trust self-respect, if not regard for the principles of self-government, will constrain the residue of the American people to say, "Go."

New York *Tribune*, 28 Dec. 1860.— . . . Nor is it treason for the State to hate the Union and seek its disruption. A State, a whole section, may come to regard the Union as a blight upon its prosperity, an obstacle to its progress, and be fully justified in seeking its dissolution. And in spite of the adverse clamor, we insist that if ever a third or even a fourth of these States shall have deliberately concluded that the Union is injurious to them, and that their vital interests require their separation from it, they will have a perfect right to seek separation; and should they do so with reasonable patience and due regard for the rights and interests of those they leave behind, we shall feel bound to urge and insist that their wishes be gratified — their demand conceded.

During the time the States were seceding Mr. Greeley published many similar statements. Nor was the *Tribune* alone, for much of the New York press and prominent journals and able editors in many of the Northern States coincided in these views. «Wayward sisters, go in peace,» was the cry on every hand, echoed from the lips of the general of the army, with the refrain uttered by the eminent Republican leader Salmon P. Chase: «The South is not worth fighting for; let them alone.» The New York *Herald*, a journal which claimed to be independent of all party influences, said on 25 Nov. 1860: «Coercion in any event is out of the question. A Union held together by the bayonet would be nothing better than a military despotism.» And the same paper said: «Each State is organized as a complete government, holding the purse and wielding the sword, possessing the right to break the tie of the confederation, and to repel coercion as a nation might repel invasion. . . . Coercion, if it were possible, is out of the question.» The New York *Times* of 3 and 4 Dec. 1860 appealed to the people of the North to repeal the State laws preventing the return of fugitive slaves and by moderation and forbearance to prevent the threatened and almost inevitable dissolution of the Union. In March 1861, after Lincoln's inauguration, the *Commercial*, the leading Republican paper of Ohio, said:

We are not in favor of blockading the southern coast. We are not in favor of retaking by force the property of the United States now in possession of the seceders. We would recognize the existence of a government formed of all the slaveholding States and attempt to cultivate amicable relations with it.

In January 1861, after six States had seceded, James S. Thayer said, at a great meeting in New York:

We can at least, in an authoritative manner, arrive at the basis of a *peaceable separation*. . . . The public mind will bear the avowal, and let us make it,— that if a revolution of force is to begin, it shall be inaugurated at home. And if the incoming administration shall attempt to carry out the line of policy that has been foreshadowed, we announce that, when the hand of black Republicanism turns to blood-red, and seeks from the fragments of the Constitution to construct a scaffolding for coercion — another name for execution — we will reverse the order of the French Revolution, and save the blood of the people by making those who would inaugurate a reign of terror the first victims of a national guillotine!

These expressions were received with enthusiastic applause. At the same meeting ex-Gov. Horatio Seymour asked whether «successful coercion by the North is less revolutionary than successful secession by the South? At the same meeting ex-Chancellor Walworth said: «It would be brutal, in my opinion, to send men to butcher our own brothers of the Southern States as it would be to massacre them in the Northern States.» Other distinguished speakers and editors throughout the North and West repeatedly expressed the same sentiments. Even Mr. Lincoln, when delivering his inaugural address on 4 March 1861, although arguing the right to secede, did not openly enunciate the right of coercion, and while asserting his intention «to hold, occupy and possess the property and places belonging to the government, and collect the duties and imposts,» said that «beyond what is necessary for these objects there will be no invasion, no using of force, against or among the people anywhere.»

Course of Secession.— The Southern States having no hope of retaining or obtaining their rights under the Constitution except by a separation from the Federal government called conventions to decide upon what course to pursue, and ended by withdrawing from the Union. South Carolina took the lead, her Ordinance of Secession being adopted 20 Dec. 1860. Six other States quickly followed her in the following order: Mississippi on 9 January, Florida on 10 January, Alabama on 11 January, Georgia on 18 January, Louisiana on 23 January and Texas on 1 Feb. 1861. As one by one the Southern States fell into line asserting their right and determination to renounce the Federal compact, the United States officials in these States, both military and civil, peacefully turned over their charge within the limits of each State to the authorities of the same, the only exceptions being the isolated fortifications of Fort Sumter and Fort Pickens. The machinery of government went on without delay, the same officials performed their customary duties, and when the provisional government was established the only change was the substituting the authority and name of the Confederate States for those of the United States. On 21 Jan. 1861 Jefferson Davis, in his speech when relinquishing his seat in the United States Senate, said:

I rise, Mr. President, for the purpose of announcing to the Senate that I have satisfactory evidence that the State of Mississippi by a solemn ordinance of her people, in convention assembled, has declared her separation from the United States. . . . If it be the purpose of gentlemen they may make war against a State which has withdrawn from the Union; but there are no laws of the United States to be executed within the limits of a seceded State. A State, finding herself in the condition in which Mississippi has judged she is — in which her safety requires that she should provide for the maintenance of her rights out of the Union — surrenders all the benefits (and they are known to be many), deprives herself of the advantages (and they are known to be great), severs all the ties of affection (and they are close and enduring), which have bound her to the Union; and thus divesting herself of every benefit — taking upon herself every burden — she claims to be exempt from any power to execute the laws of the United States within her limits . . . We recur to the principles upon which our government was founded; and when you deny them and when you deny to us the right to withdraw from a government which, thus perverted, threatens to be destructive of our rights, we but tread in the path of our fathers, when we proclaim our independence and take the hazard.

Here in the words of the man who was afterward the chosen chief of the reorganized federation, the reason for secession is given and the right of secession claimed. The senators from Florida and Alabama withdrew at the same time.

The Peace Congress.— On 19 Jan. 1861, the legislature of Virginia in extraordinary session passed a resolution requesting all the States to send delegates to Washington to meet in convention on 4 February to confer upon some feasible and possible plan upon which to settle the difficulties between the sections. The body which is known in history as the Peace Congress sat in Washington from 4 to 27 February, but accomplished nothing. Five Northern States were not represented, and while there still existed a very conciliatory spirit in many parts of the North, it was unfortunate that many prominent men were bitterly opposed to the slightest concessions to the South. The speech of Judge Chase of Ohio, afterward Chief Justice of the United States, distinctly gave it to be understood that the Northern States would make no concessions. He said:

The result of the national canvass which recently terminated in the election of Mr. Lincoln, has been spoken of by some as the effect of a sudden impulse or of some irregular excitement of the popular mind; and it has been somewhat confidently asserted that, upon reflection and consideration, the hastily formed opinions which brought about that election will be changed. . . . I cannot take this view of the result of the presidential election. I believe, and the belief amounts to absolute conviction, that the election must be regarded as a triumph of principles cherished in the hearts of the people of the free States. . . . We have elected him [Mr. Lincoln]. After many years of earnest advocacy and of severe trial we have achieved the triumph of that principle. By a fair and unquestioned majority we have secured that triumph. Do you think we, who represent this majority, will throw it away? Do you think the people will sustain us if we undertake to throw it away? I must speak to you plainly, gentlemen of the South. It is not in my heart to deceive you. . . therefore tell you explicitly that if we of the North and West would consent to throw away all that has been gained in the recent triumph of our principles, the people would not sustain us, and so, the consent would avail you nothing.

The *Congressional Globe*, Vol. 31, Part 2, p. 1247 (27 Feb. 1861) contains letters from Senators Bingham and Chandler to Governor Blair of Michigan. Senator Bingham wrote as follows:

Washington, 15 Feb. 1861.

Dear Sir:— When Virginia proposed a convention in Washington in reference to the disturbed condition of the country I regarded it as another effort to distract the public mind, and a step towards obtaining that concession which the imperious slave power so insolently demands. . . . We have been assured by friends upon whom we can rely that if those two States, Michigan and Wisconsin, should send delegations of true unflinching men, there would probably be a majority in favor of the Constitution as it is, who would frown down rebellion by enforcement of laws. . . . It cannot be doubted that the recommendations of the convention will have a considerable influence upon the public mind, and upon the action of Congress. . . .

I hope I shall be pardoned for suggesting that it may be justifiable and proper, by any honorable means, to avert the lasting disgrace which will attach to a free people who, by the peaceful exercise of the ballot, have just released themselves from the *tyranny of slavery*, if they should now succumb to treasonable threats, and again submit to degrading thraldom. . . .

K. S. Bingham.

To His Excellency, Governor Blair.

Senator Zach Chandler wrote:

Washington, 11 Feb. 1861.

My dear Governor:— Governor Bingham and myself telegraphed you on Saturday, at the request of Massachusetts and New York, to send delegates to the Peace or Compromise Congress. They admit that we were right, and that they were wrong; that no Republican State should have sent delegates; but they are here and they cannot get away; Ohio, Indiana, and Rhode Island are caving in, and there is danger of Illinois; and now they beg us, for God's sake, to come to their rescue, and save the Republican party from rupture. I hope you will send *stiff-backed* men, or none. The whole thing was gotten up against my judgment and advice, and will end in thin smoke. Still, I hope, as a matter of courtesy to some of our erring brethren, that you will send the delegates.

Truly your friend,

Z. Chandler.

His Excellency, Austin Blair.

P. S.— Some of the manufacturing States think that a fight would be awful. Without a little *blood-letting*, this Union will not, in my estimation, be worth a rush.

These letters were promptly published in the Detroit *Free Press* and also in the *Congressional Globe*. Senator Powell commenting, in the Senate, upon the letters, said: "I think it evident from these letters that there is and has been a fixed purpose in certain quarters, that the peace conference should do nothing. It is very evident that these 'stiff-backed' gentlemen were to be sent in order to prevent any compromise being presented." Senator Chandler said: "It is a question in which the people of Michigan take a great interest. They are opposed to all compromises; they do not believe that any compromise is necessary, nor do I. They are prepared to stand by the Constitution of the United States as it is; ay, sir, to stand by it to blood, if necessary." A majority of the convention or congress was sufficiently moderate to recommend a measure to Congress which would, without doubt, have preserved peace and union, but when presented to the United States Congress it was met with cool indifference, objection was made to its consideration and upon a vote it was rejected.

The failure of the Peace Congress and the finally expressed determination of the government to make no concessions and to exercise the forces of the government in coercion forced Virginia and the other so-called border States from their conservative position. Arkansas adopted an Ordinance of Secession on 15 April, and Virginia on 17 April. In the latter State the Ordinance was to be made subject to the ratification of the people late in May, but the action of the Federal government in preparing for war and the proclamation of President Lincoln calling for troops hastened her union with her sister States of the South. Tennessee passed an Ordinance of Secession on 6 May, which was ratified by the people on 8 June, and North Carolina seceded on 20 May. Such a division of sentiment existed in Kentucky and Missouri that while they did not secede they were given representation in the Confederate Congress.

Formation of the Confederate Government.— In the meantime the several conventions of the first seven seceded States appointed deputies to a congress, naming Montgomery, Ala., as the place and 4 February as the time of meeting. This assembly formed a new federation under the name of the Confederate States of America, elected Jefferson Davis of Mississippi, President and Alexander H. Stephens of Georgia, Vice-President, and drew up a Constitution establishing a provisional government, and on 11 March adopted the permanent Constitution of the Confederate States. Alexander Stephens, who knew his people, had distinctly declared that "the tendency of the large majority of Georgia is to conser-

vatism,» and this was true as well of all the other States. It was Mr. Lincoln's proclamation of 15 April that destroyed the last remaining vestige of the hope entertained by the conservatives that a return to the principles of the Constitution by the people of the North and the Federal government might bring about a reconstruction of the Union, a hope to which their hearts still clung tenaciously. Had not two States held aloof from the compact of 1787 to return in 1789 and 1790? Why might not history repeat itself? they thought and argued. The seat of government of the Confederacy was removed to Richmond, Va., and the Provisional Congress met there on 20 July 1861. At this session delegates from Virginia, North Carolina and Tennessee were added to the body. The Second Congress met on 22 Feb. 1862, with full representation from Alabama, Arkansas, Florida, Georgia, Kentucky, Louisiana, Mississippi, Missouri, North Carolina, South Carolina, Tennessee, Texas and Virginia. In the Second Congress which convened on 22 Feb. 1862, the 13 States above named were represented and delegates were present from Arizona and from the Cherokee, Choctaw, Creek and Seminole Nations.

Secession of West Virginia.—As above noted the Virginia Convention passed an ordinance of secession on 17 April 1861, which was submitted to the people and adopted by them. There was a majority against it in the northwestern part of the State. In June 1861, a convention of the Unionist counties was held in Wheeling. This convention adopted an ordinance for a reorganization of the State government, and in August adopted an ordinance providing for the formation of a new State. Most of the citizens being in the field as soldiers on one side or the other, a very small vote was polled, but a majority was for the formation of a new State. In May of 1862 the «reorganized government» of this part of Virginia passed a bill authorizing the formation of a new State. On 31 Dec. 1862, the Congress of the United States passed an act admitting the State of West Virginia into the Union, the law having the following preamble:

> *Whereas*, the people inhabiting that portion of Virginia known as West Virginia did, by a convention assembled in the city of Wheeling on the twenty-sixth of November, eighteen hundred and sixty-one, frame for themselves a Constitution with a view of becoming a separate and independent State; and whereas at a general election held in the counties composing the territory aforesaid on the third day of May last, the said Constitution was approved and adopted by the qualified voters of the proposed State; and whereas the legislature of Virginia, by an act passed on the thirteenth day of May, eighteen hundred and sixty-two, did give its consent to the formation of a new State within the jurisdiction of the said State of Virginia, to be known by the name of West Virginia, and to embrace the following named counties. . . .; and whereas both the convention and the legislature aforesaid have requested that the new State should be admitted into the Union, and the Constitution aforesaid being Republican in form, Congress doth hereby consent that the said forty-eight counties may be formed into a separate and independent State.

The End of Secession.—Although the Supreme Court of the United States several times decided that the seceded States were never *legally* out of the Union, yet for four years the secession of 11 States was an accomplished fact, and for four years the Confederate States of America was a *de facto* government, exercising, through its executive, legislative and judicial departments, all the powers and functions of a Federal government within the territory of the States which comprised it, under a constitution modeled upon the Constitution of the United States and adopted and ratified by the people of its States. In the States themselves there was no change nor interruption in any of the affairs of government except in the places which were occupied by the Federal armies. But by force of arms the Confederate government was overthrown and each of the seceded States, after a period of reconstruction, came back and took its place in the Union under the old Constitution as amended by the victorious party in the great conflict. SECESSIONISTS, the members of an association in Germany similar to that formed in the Société des Beaux Arts at Paris. The Secessionists were artists who revolted against the strictly academic and traditional spirit in which selections and awards were made by the jury which decided the hanging of pictures in the Academy of Art and distributed the medals and other awards voted to their merits. In 1892 Piglhein (q.v.), F. von Uhde (q. v.), Dill, A. Keller, Stück and others founded a new school of naturalism, and this movement in German art was greeted with the same howl of derision as that with which the Pre-Raphaelites in England had been met. The movement gained ground, especially in Munich, however, the headquarters of a strong conservative and academic coterie. The new spirit here burst into actual revolt; and the members of the «Munich Secession» actually built a new exhibition building for themselves. Their work, moreover, won public recognition and the leaven of their example did its work in vivifying German art. The movement is now merged in the Deutscher Künstlerbund founded in 1904. Consult Bierbaum, 'Fritz von Uhde'; De la Mazelière, 'La peinture Allemande au XIXe siècle' (1900).

SECESSIONVILLE, sē-sĕsh'ŏn-vĭl, **Battle of.** In May 1862, Gen. D. Hunter, commanding the Department of the South, began preparations for throwing troops upon James Island to make a quick advance upon Charleston, S. C. On 2 June the advance of Gen. I. I. Stevens was landed in the southwest part of the island, and next day made a reconnaissance in force to within a short distance of a battery at Secessionville, about two miles from Stone River, with water on three sides. It was on a narrow causeway bordered by swamps, and approachable by land only from the west. The gunboats co-operated in the movement, which was but partially successful, the Confederates, under Lieut-Col. Ellison Capers, 24th South Carolina, defending the position and inflicting upon Stevens a loss of 17 killed and wounded and taking 22 prisoners. The effect was increased watchfulness on the part of the Confederates, the strengthening of the forces on James Island and the stoppage at Charleston of troops that had been ordered to Richmond to resist McClellan. On the 8th Stevens made another reconnaissance, came under artillery fire and withdrew with a loss of seven killed and wounded. On the same day General Wright's division arrived from Edisto

Island and the next day marched to near Grimball's Landing, two or three miles to the left of Stevens, who was covering the position opposite Legareville, on John's Island. It was determined to carry the battery by a rush, and thus open the way to Charleston, but 10 miles distant; and orders were given for an assault to be made at dawn of 11 June, but Col. T. G. Lamar, in command of the Confederate works at Secessionville, assumed the offensive and toward evening of the 10th attacked Wright's pickets and advance posts with infantry and artillery and was repulsed, suffering severe loss and inflicting upon Wright a loss of about 25 killed and wounded. This caused a postponement of the assault and the beginning of the construction of a battery to silence the Confederate guns. General Hunter, disappointed in his expectation of carrying Charleston with a rush, returned to Hilton Head on the 11th, leaving orders with General Benham, next in command, to make no attempt to advance on Charleston or on Fort Johnson until largely reinforced but to provide, however, for "a secure intrenched encampment." At the end of five days the battery had been constructed, but it failed to silence the Confederate guns, and Benham, as Hunter says, "disobeyed positive orders and clear instructions" and against the emphatic protest of his two division commanders proceeded to assault the work. He had for the purpose 3,100 men under General Wright and 3,500 under General Stevens. The work to be assaulted had an earthen parapet seven to eight feet high, outside of which was a ditch seven feet deep and in front of which was a strong abatis. A line of rifle-pits extended on both flanks and in the rear, sweeping the open interior of the work. Its armament was six heavy guns — 8-inch columbiads and rifled 24- and 18-pounders. It was defended by about 1,000 men, and there were supports near that came at the close of the action. Stevens, with his 3,500 men, was to make the assault and Wright, moving from Grimball's Landing, was to co-operate by moving on his left and rear. Stevens had two brigades, Colonel Fenton's (8th Michigan, 7th Connecticut, 28th Massachusetts) and Colonel Leasure's (46th and 79th New York and 100th Pennsylvania), and four guns. At 3.30 A.M., the troops were assembled beyond the camps and at 4 A.M., when it was so dark one man could not follow another except at short intervals, the column moved forward, Fenton leading, with a storming party of two companies of the 8th Michigan, closely followed by the other eight companies of the regiment, the 7th Connecticut and the 28th Massachusetts. Leasure followed Fenton. The advance moved quietly and when within 800 yards of the work surprised and captured a small picket-guard without firing a shot and orders were given to accomplish the allotted task with the bayonet only. Lamar had knowledge of the movement and had sent for reinforcements and was standing by his heavy guns, which had been charged with canister, as the leading regiment came within 300 yards and deployed into line; then his guns opened their canister-fire, and at the same time heavy volleys of musketry from dikes and hedges were poured upon the right flank of the assaulting column. The Union regiments closed up rapidly and made a rush for the work, shooting down the gunners; all the regiments got close to the work and men of each went through the abatis; men of the 8th Michigan and 79th New York gained the ditch and scaled the parapet. "Some of them," says Beauregard, "in the impetus of the assault went even inside one of the salients of the works"; but it was of no avail; the mingled Union troops could not be handled and at 5 o'clock, after a severe contest of 25 minutes, they fell back 500 yards to a hedge, under cover of artillery, with a loss of over 500. Wright had participated in the movement by checking a reinforcement on its way to the work, but did not become seriously engaged, although losing some men. At 9 o'clock Benham ordered Stevens back to camp. The Union loss was 107 killed, 487 wounded and 89 missing, an aggregate of 683. The Confederates report a loss of 52 killed, 144 wounded and 8 missing. The result of the battle was fatal to the plan of an immediate advance on Charleston and late in June the Union troops were ordered to withdraw from James Island and for some time to come no further attempt was made to capture the city. Consult 'Official Records,' Vol. XIV.

SECHEM, Palestine. See NABULUS.

SECHIUM, a genus of the gourd family (*Cucurbitaceæ*) with one species (*S. edule*). This is a perennial, rough-stemmed, climbing vine native to the West Indies and the neighboring mainland, sometimes cultivated for covering arbors, since it makes a rapid and sturdy growth, but chiefly for the valuable food afforded by its roots and fruits. It has large, thin, heart-shaped leaves five-angled like those of the cucumber; branched tendrils opposite the leaves, and yellowish, monœcious flowers, the pistillate solitary or paired in the axils, the staminate in a raceme. These flowers have rotate calices and five-parted corollas and a one-celled ovary with six-lobed stigma, which matures into a pear-shaped fruit, some six inches long. It has an irregularly ribbed or furrowed surface slightly spiny, but shining, and in color ranging from pale green to creamy tints; the interior is fleshy and white, and contains a large flat seed, which germinates within the pericarp, often before it falls from the vine, so that the whole fruit is planted. This fruit is edible, as is also the very large, corky and starchy root-tuber, sometimes weighing 20 pounds, and both are cooked as vegetables having somewhat the flavor of turnips. The sechium fruit is called vegetable pear in the British colonies, and has local names such as chayote or pepinella.

SECKENDORF, Friedrich Heinrich, frēd'rĭH hīn'rĭH zĕk'ĕn-dôrf, COUNT VON, Franconian soldier and diplomat: b. Königsberg, 5 July 1673; d. Meuselwitz, Germany, 23 Nov. 1763. He served in the war against the Turks on the Danube, and in that of the Spanish Succession, greatly distinguished himself at Blenheim in 1704 and was present as an Ambassador at the conclusion of the Peace of Utrecht. He also served in the war against Sweden, 1715, and against the Spaniards in Sicily, 1720. In 1726 he was Ambassador to Berlin and gained over Frederick William I to acknowledgment of the pragmatic sanction and an alliance with Austria.

Seckendorf next served in the War of the Polish Succession, gaining victory over the French at Klausen. During the Turkish War he was made field marshal in 1737, and commander in chief. He was unsuccessful, however, and was recalled and imprisoned in the fortress of Grätz. Receiving no appointment when released, he entered the service of Charles VII of Germany against Maria Theresa. He cleared Bavaria of Austrian troops, but on the emperor's death in 1745 peace was established and Seckendorf was restored to his Austrian honors. He retired to his castle at Meuselwitz, but in 1758 was imprisoned by Frederick II of Prussia, on a charge of intriguing against that country, and was only released after six months upon the payment of 10,000 thalers.

SECOND, a division of time, the 60th part of a minute of time or of a minute of a degree. The hour and degree are each divided into 60 minutes (marked thus, 60′), and each minute is subdivided into 60 seconds (marked thus, 60″).

SECOND ADVENT OF CHRIST. See MILLENNIUM.

SECOND ADVENTISTS. See ADVENTISTS.

SECOND CENTURY. Many scholars agree with Edward Gibbon in looking back to the 2d century as the acme of ancient civilization: "If a man were called to fix the period in the history of the world during which the condition of the human race was most happy and prosperous, he would, without hesitation, name that which elapsed from the death of Domitian to the accession of Commodus"—that is, from 96 to 180 A.D. (*Decline and Fall of the Roman Empire,* vol. 1, chap. 3, 1776).

When the 2d century began the Roman Empire embraced the whole civilized world of the West, about the shores of the Mediterranean Sea, an area between 1,500 and 2,000 miles in breadth by about 3,000 miles in length, that is, an area of nearly 2 million square miles of fertile and productive land, with a population that has been estimated at between 75 million and 100 million. Politically the empire was still a military monarchy, but the evils of absolutism, especially as combined with emperor worship, were somewhat mitigated during the period between Domitian and Commodus, and a series of able rulers, the ablest since Augustus, governed this vast region with justice and efficiency. Men were aware of the signal benefits of the new era, following the unbearable tyrannies of such rulers as Caligula, Nero, and Domitian. Trajan forbade Pliny the Younger, the governor of Bithynia, to pay attention to anonymous informers against the Christians; such a procedure was "unworthy of our enlightened age." In turn the governor repeatedly stressed the "tranquillity and public order" which characterized the new era.

THE EMPERORS OF THE 2D CENTURY

The period comprising the final years of the 1st century and most of the 2d century was the age of the five "good" emperors: Nerva (r. 96–98), Trajan (r. 98–117), Hadrian (r. 117–138), Antoninus Pius (r. 138–161), and Marcus Aurelius (r. 161–180). Following them, the swift decline which began with Commodus (r. 180–192) led to the vast disorder and mounting crises of the succeeding centuries. Pertinax and Didius Julianus (193) openly made financial bids for the imperial succession but were followed at once by Septimius Severus (r. 193–211) who was the choice of the army. The legions had made and unmade rulers in the days of the triumvirs (1st century B.C.) and again in the year of the four emperors (69 A.D.); from the reign of Commodus onwards they were to play once more an increasing role in the making and unmaking of monarchs. Against the background both of what went before and what followed after, the reigns of the five good Spanish emperors (most of them were at least of Spanish descent) appeared to later historians and to contemporaries alike as a kind of golden Indian summer, which lingered for almost a century before the frosts and storms of the long dark winter set in.

Nerva.—Marcus Cocceius Nerva was a distinguished senator and jurist, chosen by the Senate to succeed the despotic Domitian when he was assassinated in September 96 A.D. Since Nerva was 66 years old, it was obvious that his election was only a temporary solution. Yet even in his brief reign he did much to re-establish peace and confidence, especially in remote regions. His crowning achievement was the appointment of his successor, the ablest administrator and general in the army, Trajan, then at Cologne.

Trajan.—More than anyone else Trajan (Marcus Ulpius Trajanus) laid the foundations of peace and prosperity for the Antonine age. By 107 A.D. he had overcome the inherited deficit, and with fresh supplies of precious metal taken in his Dacian Wars (101–102; 105–106), and with 50,000 able-bodied prisoners, he embarked upon a vast program of public works in which the provinces vied with Italy. Trust funds were set up for the care of the poor and for public education of freeborn children, partly no doubt in the interest of maintaining the free Italian population in the face of rising foreign-born groups. The impetus to architecture continued through the reign of Hadrian; forums, baths, theaters, basilicas, circuses, hippodromes, aqueducts, harbors, the impressive ruins of which survive to this day, attest the wealth and magnificence of the period.

The Dacian Wars extended the boundary of the empire to its farthest northeastern limit. That frontier now extended 1,300 miles from the mouth of the Rhine to the mouth of the Danube. Only one strip lay open, between the east bank of the Danube and the west bank of its tributary the Theiss (Tisza); a Roman wall at its southern end converted this 200-mile corridor into a cul-de-sac, and, thus protected, Dacia (q.v.) remained Roman until the Gothic invasions of 250–270. The whole later history of Europe would undoubtedly have been very different had the Roman Empire enjoyed another century of peace and prosperity, and been able to extend its northeastern border to the Elbe, the Oder, or the Vistula; if this had occurred a much shorter line could have been completed via the Carpathians to the southeast, one which might later have held the Huns in check.

Trajan's victories in the East resulted in the creation of new provinces: Armenia (114), Mesopotamia (114–115), and Nabataea (105), where a permanent road was built (111–114) from the borders of Syria to the Red Sea in which a Roman fleet was stationed. Trajan died while returning from an expedition against the Parthians, and his annexation of Armenia and Meso-

potamia was promptly repudiated by Hadrian. There was in fact no natural frontier on the east, any more than on the northeast, and this set a problem which was destined to vex Roman policy while the empire lasted. Theoretical lines drawn along the Caucasus Mountains from the Black Sea to the Caspian Sea, and from the Caspian Sea to the Persian Gulf, or following the mountains and deserts to the Gulf of Oman, would have sufficed to hold back only theoretical foes—not the nimble Parthians who could leap any wall, swim any river, and had been born to the saddle. The withdrawal by Hadrian was the only sensible thing to do, but it was a signal observed by the whole barbarian world. Rome was never able to assimilate, that is, to Romanize, these far eastern territories lying beyond Syria and the Euphrates River. On the south, the borders of the empire were extended to the Sahara and the Libyan deserts, and in the African provinces the building operations of the north and west were repeated.

Hadrian.—Hadrian (Publius Aelius Hadrianus) was a very different person from Trajan, though his cousin. His versatility was world-famous; he was a patron of literature and art, and especially generous to the ancient Greek cities where classical civilization had been born. The ruins of his villa at Tivoli still attest his unbounded enthusiasm for art, literature, mythology, and archaeology. Like most of the good emperors, he was a tolerant, cosmopolitan, and enthusiastic promoter of the common good. More than half of his time was spent in the provinces, Hellenizing, Romanizing, and organizing their social and political life. He encouraged the work of the great jurists in collecting, codifying, and expounding the whole body of Roman law. He insisted upon freedmen occupying posts of responsibility in the government, and made the civil service a profession sufficiently lucrative to attract well-trained men. He instituted the famous Roman postal system.

Unlike Trajan, Hadrian was not a professional soldier, although he successfully concluded the Jewish War of 132–135. But the madness which cursed his later years had been already apparent when he provoked that war by decreeing the erection of a pagan city, Aelia Capitolina, on the ruins of Jerusalem, with a temple to Olympian Zeus (Juppiter), now identified with himself! The whole Jewish world rose in revolt. His increasing megalomania and self-identification with deity led also to the opposition of the Christians, who refused to acclaim him *dominus et deus*—the same opposition Domitian had aroused, and which had led to the protest of the Revelation of John (q.v.).

Hadrian's plaintive death song, the oft-quoted *Animula, vagula, blandula* ("Little soul, little wanderer, little darling, soon to go down to the cold, pale, naked underworld, never to smile again . . ."), is not the language of the great emperor in the heyday of his power and magnificence, and should not be viewed as characteristic of him. The man was sick, physically and mentally, indeed he was dying. But the verses do reflect the enfeeblement of spirit which was steadily sapping the inner vitality of the empire, for all its external splendor and apparent prosperity.

Antoninus Pius.—Much less is known about Antoninus Pius: his virtues were of the modest kind, and he had no vices to make his life interesting to the scandalmongers. What Marcus Aurelius says of him is enough to convince us that his reign of 23 years must have been one of the happiest in all history. He was a true "father of his country." Under him "all the provinces flourished." By his economical administration the treasury accumulated a large surplus. Under his peaceful reign the spread of the Oriental cults, especially the cult of the Unconquerable Sun, took on new impetus, and along with them went a renewed emphasis on astrology—but also a greater propaganda for popular philosophy. During his reign, in 147, came the 900th anniversary of the founding of Rome; the Alexandrians hailed him as the World Redeemer Heracles, the benefactor of all mankind. In this aura of pagan sanctity he laid down his life peacefully at Lorium in March 161.

Marcus Aurelius.—Perhaps the most interesting of the good emperors was the last, Marcus Aurelius Antoninus, who reigned for the next 19 years. We know more about Marcus Aurelius, as a man, than about any other Roman emperor, since his *Meditations* (or, better, "A book for myself") contains his whole life-philosophy; it is one of the noblest documents of ancient Stoic piety and speculation, and along with the works of Seneca and Epictetus the fullest exposition of the later Roman type of Stoicism.

But it was Marcus' ill fortune to be compelled to face the accumulated liabilities and the mounting misfortunes which had resulted from the long era of prosperity following Trajan. During these 44 years the Parthians in the east and the German tribes north of the Danube had bided their time and were now ready to seize the territory of what they assumed to be the feeble because pacific power of Rome. Under the able generalship of Avidius Cassius, the Romans repulsed the Parthians, and the two capitals of Parthia, Seleuceia and Ctesiphon, were captured and destroyed (164). The victory was a costly one, however, for the Roman troops brought home with them a plague which spread everywhere and decimated the whole population of the west and north, as far as the Rhineland. It lasted for many years, and may have been one of the causes which led to that strange loss of vitality which characterized the decline of the empire in the following centuries. The restive northern tribes which invaded the Danube Valley and northeastern Italy in 167 were completely defeated by 180; but the effort required the absence of the emperor from Rome during much of this time—Book I of his *Meditations* ends, "Among the Quadi."

This absence was most unfortunate for Marcus, both personally and publicly; these were the years when his son and successor, Commodus (b. 161), was growing up. Lacking firm parental restraint, the young prince became utterly spoiled and irresponsible. The colossal blunder of Marcus in appointing his own son as his successor blots out much of the solid achievement of his difficult but nobly pursued career. There was never a Roman ruler more devoted to the highest conceptions of public duty; and surely there was never a more tragic instance of parental blindness.

Commodus.—The ill-starred reign of Lucius Aelius Aurelius Commodus lasted for 13 years. The poison of autocratic power seems to have unbalanced his mind. Commodus persecuted the Senate, renamed Rome after himself, *Colonia*

Commodiana, and named the months after his own names and titles, 12 in number. As the incarnation of Hercules he planned to appear publicly on Jan. 1, 193, as both consul and gladiator; but his mistress Marcia, his chamberlain Eclectus, and his praetorian prefect Laetus conspired to have him put out of the way.

The century ended in gloom and foreboding of worse things yet to come. The two puppets who followed Commodus were short-lived, and then, in 193, began the dynasty of the Severi, who had little regard for Roman traditions but were oriented toward the East. So powerful and well established was the new *Imperium Romanum* that it could not die overnight; yet its decline had now begun, and sooner or later its eventual fall was inevitable. The closing years of the 2d century were a twilight following a sunny day—a deepening twilight which presaged the long night of storm and tempest that followed.

PEACE AND PROSPERITY IN THE ROMAN EMPIRE

Yet while it lasted, the era of peace and prosperity under the good emperors brought to the world blessings which have never been wholly lost or forgotten. For once in history, this was a period without serious threat of invasion from without or of revolution within. For three generations and more, men lived in a civilized society and passed on to their barbarian neighbors the accumulated inheritance of learning, art, letters, philosophy, and the science of government—an inheritance which began in the Hellenistic age and, in spite of threats and reverses during the interval, had really grown in magnitude and significance. In fact, the civilizing (that is, Hellenizing) process begun in the Near and Middle East by Alexander the Great was now being carried to its conclusion in the West. For example, Greek was still spoken and written in Italy, Gaul, and North Africa. Hermas in Rome and St. Irenaeus in Gaul wrote in Greek, and the persecuted churches in Vienne, near Lyon, c.177 wrote their accounts of the martyrdoms in Greek. The Old Latin Version of the Bible was begun c.150, but hitherto the Greek text had served in North Africa, Italy, and Gaul. Even the *Meditations* of the emperor Marcus Aurelius were written in Greek.

Government.—Although the emperors were now virtually absolute dictators, since the Senate had declined in influence for over a century, the government was efficient, staffed largely by men of the equestrian order; taxes were moderate, and were collected now by officials rather than by tax farmers; the law was studied scientifically, and accurately codified; vast building operations were undertaken not only in Rome but in the provinces, especially under Hadrian; the city governments were well organized; public schools were established; farm relief was provided through government loans, the interest being used to educate poor country children; slavery was dying out, and it was easier for slaves to obtain freedom; world trade had reached its utmost expansion—even silk from China and cotton from India could be purchased in the cities of the West.

Intellectual and Religious Life.—Some of the great writers of later antiquity belong to the 2d century: the historians Cornelius Tacitus, Dio Cassius, Suetonius, Arrian; the philosophers Epictetus and Marcus Aurelius; the essayist and biographer Plutarch; the satirists Lucian and Juvenal; the novelist Apuleius; the orator Dio Chrysostom; the traveler Pausanias; the physician Galen; the geographer and astronomer Ptolemy; the letter writers Pliny the Younger and Marcus Cornelius Fronto. Among Christian writers some of the later New Testament authors belong early in the 2d century, and following them, the Apologists, then Tertullian and St. Irenaeus. Yet with all the intellectual and religious activity of the age, and its general contentment and security, there was little indication of fresh progress. Rhetoric, that is, oratory, was still the crown of education, not philosophy, science, or history.

The ancient religious cults were dying; for the majority, astrology and the Oriental mysteries had taken their place—such cults as those of Isis, Cybele, and Attis, and, above all, Mithras. For the educated, a refined type of personal philosophy sufficed, usually Stoicism or a revived and purely spiritual type of Platonism. The most vital religious movement of the period was Christianity, which had reached a point by c.197 where Tertullian could say, "We are of yesterday, yet we penetrate your courts, your markets, your armies" (*Apology,* 37). The persecutions, thus far, had been only local and sporadic, usually outbursts of mob violence, as in Bithynia in 112 or at Vienne in Gaul in 177. The widespread official efforts to stamp out the new religion came later, under the emperors Decius and Diocletian.

Spread of Roman Culture.—The civilizing mission of Rome was accomplished, not by coercion or restraint or by force of arms or the transplanting of populations, but by the peaceful methods of example, public education, the just administration of law, a widespread commerce, and by the ubiquitous establishment of cities, towns, and country villas in which the urbane Roman type of life was cultivated, exemplified, and enjoyed. Civilization was thus made attractive to multitudes of peoples along the far-flung frontiers of the empire and among the nations only recently incorporated within it. Whatever it had been originally, it was now a self-sustained culture, expanding by its own inner attractiveness to other peoples. The tragedy, for all later history, is that it ended too soon, before its task was done, and before it had reached and transformed more of the barbarian and savage peoples to the north and east, whose onslaughts on the Roman world in the 4th and 5th centuries almost extinguished European civilization. Where Roman culture had really taken root, it survived to some extent the Dark Ages that followed, and in turn passed on its blessings to the new peoples.

This culture was not limited to the provincial aristocracy, although naturally it was centered in the upper classes. Emperor Caracalla's grant of Roman citizenship to all freemen throughout the empire, in 212, was only the climax of a long process of education and preparation for responsibility, a process more marked in the provinces than in Rome itself, where a large part of the populace still lived on the dole, and where it was possible for landless farmers and vintners from every part of Italy and for the drifting unemployed of a whole empire to gather and be fed.

Economic Conditions.—It is estimated that the city of Rome in the 2d century had a population of over a million, of whom perhaps a fifth were idle, supported by the state, both fed and

amused at public expense. The same luxury and extravagance were found in the provinces, though in less degree. At no time in all history, until quite recently, have the masses enjoyed such comfort or such luxurious surroundings. Unfortunately this luxury and the general superficial prosperity which made it possible did not prevent the extinction of many of the upper-class and upper-middle-class families. The equestrian class grew, but only by adoption and recruitment from outside.

Economically, a kind of stagnation seems to have been increasing; the rich had most of the wealth, and lacked all incentive to increase it; the poor were content with "bread and circuses"; the middle class, in between, seemed satisfied with free public baths, public spectacles, free education, and the general security and opulence which surrounded them, and above all with the comparative freedom to pursue any religious cult or philosophy that attracted their attention or interest.

In the eastern provinces, manufacture was thriving, and the finished wares of Syria and Asia Minor were as well known in Rome as Egyptian grain and cotton goods. The port of Ostia was a thriving headquarters of Mediterranean trade, as its ruins prove; it had completely outstripped Puteoli (Pozzuoli), which was too remote for the transshipment of the vast cargoes of food and other supplies destined for the metropolis. Trade and transport were ubiquitous, and thus had an immense effect upon the spread and establishment of a worldwide common culture.

FREDERICK C. GRANT,
Union Theological Seminary.

PRINCIPAL EVENTS OF THE 2D CENTURY

101–106—Trajan's wars against the Dacians.

112—Dedication of the Forum of Trajan.

114–115—Annexation of Armenia and Mesopotamia (renounced in 117 by Hadrian).

116—Jewish revolt in Egypt, Cyrene, and Syria.

120–124—Pantheon constructed.

122–128—Hadrian's wall built across northern England.

132–135—Revolt of the Jews; final destruction of Jerusalem.

135—Temple of Venus and Rome dedicated.

139—Mausoleum of Hadrian dedicated.

152–153—Revolt in Egypt.

164—Destruction of Parthian capitals, Seleuceia and Ctesiphon.

165–166—Plague spreads from Parthia to the West.

167—Invasion of northern Italy by the barbarians.

169–175—War against the Germans and Sarmatians.

175—Revolt of Avidius Cassius in Syria.

196—Capture and sacking of Byzantium by Septimius Severus.

SECOND EMPIRE. See FRANCE—*History: 1815–1914.*

SECOND INTERNATIONAL. See INTERNATIONAL.

SECOND WORLD WAR. See WORLD WAR II.

SECOND WORLD WAR, The, by Sir Winston S. Churchill, English statesman and writer. The six volumes of this history of World War II give a vivid, panoramic account of the struggle and its surrounding drama, as seen by a man uniquely placed to observe the course of events and in some degree to guide and direct them. A common moral links the separate books: "In War: Resolution; In Defeat: Defiance; In Victory: Magnanimity; In Peace: Good Will." Throughout the epic story Churchill pays tribute to the contribution of the United States to the liberation of the Old World from Nazi bondage, holding in particular esteem and affection President Franklin D. Roosevelt as leader and man, England's "great friend."

The Gathering Storm (London and New York 1948), the first volume of the series, covers the false peace following World War I, the rise of Hitler, the failure of appeasement, and the first engagements of World War II.

Their Finest Hour (1949), starting with Churchill as prime minister in 1940, traces the collapse of France and the heroic deliverance at Dunkirk. It reviews the stark years when England stood alone against the triumphant Nazi power and rose to new heights of heroism, inspired by Churchill's declaration that her people would fight on the beaches and in the streets but would never surrender.

The Grand Alliance (1950) deals with Germany's drive into the heart of Russia, the Battle of the Atlantic, the forging of the Atlantic Charter, the attack on Pearl Harbor, and the entrance of the United States into the war.

The Hinge of Fate (1950) unfolds a tale of disaster, with the Japanese sweeping down to Singapore while Field Marshal Erwin Rommel plays havoc in North Africa, followed by an equal period of magnificent successes: the British and American air strikes against Germany, the titanic Battle of Stalingrad, the Battle of Alamein, and the triumph of United States forces in the Coral Sea.

Closing the Ring (1951) begins with the summer of 1943 and depicts the ignominious end of Mussolini, the defeat of Italy, the Teheran Conference, and the Allied entry into Rome. It ends a year later, just before the immense armada of sea and air began to move across the English Channel to converge upon Normandy for the liberation of France and Europe.

Triumph and Tragedy (1953), the final vol-

ume, opens with the mighty assault of D-Day and follows the many-pronged attacks upon Germany until Hitler's suicide and Germany's unconditional surrender. It leaps across the world to tell of the atomic bombing of Japan and her capitulation shortly after. And finally it describes the melancholy events following the winning of the war: the shattered Russian promises after Yalta, the death of Roosevelt, and the repudiation of Churchill in the general election of 1945. The book ends on a tragic note as the nations of the world, far from peace, face even greater problems in an atmosphere envenomed by new hatreds.

SECONDARY EDUCATION. See EDUCATION, SECONDARY, IN AMERICA.

SECORD, sē'kôrd, **Laura,** Canadian heroine: b. Massachusetts, 1775; d. Chippawa, Ontario, Canada, Oct. 17, 1868. Following the Revolutionary War, she moved with her family to Canada. In 1813, overhearing plans by American troops billeted in her house for an attack on British forces at Beaver Dams, she hurried through the American lines to warn the British, who then surprised and routed the Americans.

SECRET SERVICE, United States.—A branch of the Treasury Department, the Secret Service is one of the oldest federal law enforcement agencies. Its duties are defined by law (Title 18, U.S. Code, sect. 3056), and they include the following:

(1) Protection of the person of the president of the United States; the members of his immediate family; the president-elect; and the vice president at his request.
(2) Suppression of the counterfeiting of the coinage, currency, stamps, and other obligations and securities of the United States.
(3) Suppression of the forgery and fraudulent negotiation of government checks, bonds, and other obligations or securities of the United States.
(4) Investigations relating to certain criminal violations of the Gold Reserve Act of 1934; the Silver Purchase Act; the Federal Deposit Insurance Act; the Federal Land Bank Act; the Federal Farm Loan Act; the Home Owners Loan Act; and the Government Losses-in-Shipment Act.
(5) Investigations pertaining to thefts of government property under control of the Treasury Department, as directed by the secretary of the treasury.

Prior to 1860, Congress had passed several laws to suppress counterfeiting, but it had not provided any funds to enforce those laws. The paper money in circulation was privately printed by individual banks in some 3,000 varying designs, and there was no standard federal paper money. When the act of Feb. 25, 1862, and that of June 3, 1864, authorized the issuance of United States notes and national bank notes, respectively, Congress acted to protect the new money against counterfeiting, and the Secret Service was established July 5, 1865, with William P. Wood as its first chief.

At that time there was no other general federal law enforcement agency, and it became the practice for governmental departments other than the Treasury Department to request the use of Secret Service agents to investigate various law violations. For example, in 1898 the Secret Service organized a counterespionage organization to combat and expose a Spanish spy ring operating in Canada against the United States during the Spanish-American War. Agents located the headquarters of the ring in Montreal, Canada, and exposed Lieut. Ramón Carranza, naval attaché of the Spanish legation, as its mastermind. Carranza was banished from Canadian soil by the Dominion government, and with the arrest of other spies in the United States, the Secret Service put an end to the Spanish spy system.

The most important duty of the Secret Service is the protection of the person of the president of the United States, which has been its responsibility since 1901. In that year President William McKinley was shot and killed at Buffalo, N. Y., the third president of the United States to meet death by assassination. When Theodore Roosevelt succeeded McKinley, he was protected by agents of the Secret Service, and in an appropriation act dated June 30, 1906, Congress provided funds for the protection of the person of the president by the Secret Service. On June 23, 1913, this protection was extended to the person of the president-elect and on June 12, 1917, provision was made to include the members of the president's immediate family. On July 16, 1951, Congress authorized the Secret Service to protect the vice president, "at his request."

Agents went to Panama with President Theodore Roosevelt, the first president to set foot on foreign soil while in office. Agents guarded President Woodrow Wilson during his European visit after World War I. They went to Alaska with President Warren G. Harding. They protected President Franklin D. Roosevelt during his trips to South America, Casablanca, Teheran, Cairo, Pearl Harbor, the Aleutian Islands, Canada, Mexico, and throughout the United States. They were with President Harry S. Truman during the famous Potsdam Conference, and in Canada and Mexico. They made advance preparations for President Dwight D. Eisenhower's historic journey to the Korean battle zone when Mr. Eisenhower was still president-elect, and safeguarded him while there. They remain with the president at all times, whether in the United States or abroad.

On May 14, 1930, the White House police force, organized in 1922 to protect the executive mansion and grounds, was placed under the supervision and control of the chief of the United States Secret Service.

Rulers of foreign countries and members of foreign missions in the United States were at one time protected by the Secret Service during their stay in this country. This duty was subsequently transferred to a newly organized security division of the Department of State.

Law enforcement activities of the Secret Service have been many and varied. During the Civil War, one of the most extensive legal lotteries in the world was organized in New Orleans. Known as the Louisiana Lottery, it received in cash some $300 million, of which only a small portion was paid out in prizes. Through the manipulation of numbers and other crooked practices, many of the lottery owners became multimillionaires. In 1902 the Department of Justice borrowed Secret Service agents who were assigned to suppress the lottery activities, and from 1902 to 1908 the agents made numerous arrests and seizures, which finally ended the enterprise.

By 1905, at the request of the attorney general of the United States, some 32 Secret Service agents were lent to the Department of Justice to investigate extensive frauds against the government, especially frauds resulting from passage of

the Homestead Act of 1862, which threw free lands open to homesteaders. Many of the Western cattle barons used dummy entrymen to gain rich grazing lands for their herds, and other unscrupulous landowners claimed land for agricultural purposes, but actually robbed it of coal, oil, and timber. Secret Service agents exposed numerous land frauds and recovered millions of acres for the government. Congress in 1907 restricted the work of the Secret Service to its normal Treasury Department duties and prohibited the loaning of its agents to other governmental units. Several Secret Service agents were then permanently transferred to the Department of Justice and other governmental departments and formed the nuclei around which subsequent investigative units were established.

The restrictions imposed upon the Secret Service by Congress were temporarily lifted on May 14, 1915, when President Woodrow Wilson directed Secretary of the Treasury William G. McAdoo to use the Secret Service to uncover violations of neutrality. One of the most startling incidents of the World War I followed this assignment. Secret Service agents in New York City on July 24, 1915, shadowed George Sylvester Viereck and Dr. Heinrich Albert, both of whom were active German propagandists in the United States. At the 50th Street station of the Sixth Avenue elevated line, Dr. Albert left his seat and momentarily forgot a brief case which he had been zealously guarding. Instantly, Frank Burke, the Secret Service agent watching Albert, seized the case and left the train. Agent Burke was pursued by Albert but cleverly eluded him. The brief case was delivered to Secretary McAdoo. Its contents proved that Germany was deliberately violating the neutrality of the United States; that German agents had completed elaborate schemes to influence public opinion by buying newspapers and establishing news services; and that a periodical called *The Fatherland,* edited by George Sylvester Viereck, was on the German payroll for $1,500 a month. The German government, according to the seized papers, planned to organize strikes in American munitions plants; to corner the supply of liquid chlorine, used for poison gas; to acquire the Wright Aeroplane Company and its patents and use them in German interests; to cut off from England the supply of cotton and make it appear that the stoppage had originated spontaneously among the Southern cotton growers. It was disclosed that Germany, through its agents, had actually purchased a large munitions plant at Bridgeport, Conn., the ownership of which was concealed under an assumed name. Orders for shells were received from Great Britain and Russia, but the Germans never intended to make deliveries. The Albert papers were published in the New York *World* by permission of Secretary McAdoo, but the facts surrounding seizure of the brief case were not made public until 1931, when they were included in McAdoo's autobiography *Crowded Years.*

Secret Service agents were also active in investigating the Teapot Dome oil scandals. In 1915, President Wilson designated an area in Wyoming, embracing about 9,481 acres of oil land known as Teapot Dome, as a naval oil reserve. Subsequently, Congress discovered that a lease of the entire reserve had been executed April 7, 1922, to the Mammoth Oil Company, without competitive bidding. More irregularities affecting other oil lands were then unearthed, and Congress directed the president to cancel leases of oil contracts and to appoint special counsel to conduct necessary litigation and prosecution.

At the suggestion of President Coolidge, the special counsel enlisted the cooperation of the United States Secret Service. Its agents were assigned to the investigation of the oil scandals and worked for about three years before their association with the investigation became generally known. The intensive efforts of the government resulted in several convictions and the collection by the government of several million dollars in taxes, penalties, and interest.

In its work of suppressing counterfeiting, the Secret Service is constantly active. The volume of counterfeit money circulated in the United States has fluctuated widely through the years. The peak appears to have been reached in the middle 1930's, when several large gangs organized extensive operations from plants set up in the eastern part of the nation. The destruction of these gangs by the Secret Service and the conviction and imprisonment of scores of the counterfeiters and passers brought a prompt and drastic reduction in bogus money losses to the public. Supplementing its enforcement methods, the Secret Service uses crime prevention methods to keep counterfeiting down. Its agents show handlers of money, including the general public, how to distinguish the genuine from the counterfeit. Special training has been brought to bank employees and other commercial handlers of cash, and an effective system for quick dissemination to such agencies of warning notices and details of new counterfeits as they appear has been an integral part of this crime prevention program. In addition, under the slogan, "KNOW YOUR MONEY," instruction in the detection of counterfeits has been carried to the public through the high schools of the country and through motion pictures, radio, lectures, and newspaper and magazine articles.

Similar preventive methods supplement the enforcement work of the Secret Service in the suppression of forgery of government checks, more than 300 million of which are issued annually. As the result of Secret Service recommendations, these checks bear the pertinent warning "KNOW YOUR ENDORSER—REQUIRE IDENTIFICATION." This warning is the basis of the Secret Service efforts to prevent forgery, by cautioning merchants and other potential victims of the forger to establish to their complete satisfaction the identities of strangers who present checks for payment.

The chief of the United States Secret Service supervises and directs its field and departmental forces, the White House police force, and the Treasury guard force which protects the Treasury Building and vaults. The men appointed as chiefs of the Secret Service and their terms of office since its establishment have been:

William P. Wood	1865–1869
Herman C. Whitley	1869–1874
Elmer Washburn	1874–1876
James Brooks	1876–1888
John S. Bell	1888–1890
A. L. Drummond	1891–1894
William P. Hazen	1894–1898
John E. Wilkie	1898–1911
William J. Flynn	1912–1917
William H. Moran	1917–1936
Frank J. Wilson	1937–1946
James J. Maloney	1947–1948
U. E. Baughman	1948–

The Secret Service has 57 field offices throughout the United States and in Hawaii and Puerto Rico. Each office is under the direction of a special agent in charge, who reports directly to the chief. However, for administrative purposes the chief has divided the country in four regions, each under the supervision of a regional inspector with headquarters in Washington. At least once annually each field office is thoroughly inspected by an inspector, who thus maintains a close liaison between the chief and the special agents in charge.

Special agents of the Secret Service are appointed under rules of the United States Civil Service Commission and must pass the examination prescribed by the commission. Their training includes not only on-the-job instruction, but also intensive courses in special Treasury and Secret Service schools, where the agents are educated in such subjects as the expert use of weapons, *modus operandi* of counterfeiters and forgers, study of the manufacture of paper money and coins, the principles of protection, the handling of bombs and explosives, interrogation, shadowing, and other phases of modern law enforcement.

The chief of the Secret Service, each special agent in charge, and each special agent carries an engraved silver badge in the shape of a five-pointed star with the inscription "U.S. Secret Service" in the center portion. In addition, he carries a commission which bears his photograph, printed name, title and signature, together with the signature of the chief. The commission is mounted in a fabricated case, the outer cover of which bears an embossed gold reproduction of the Secret Service badge.

See also COUNTERFEITING.

U. E. BAUGHMAN,
Chief, U.S. Secret Service.

SECRET SOCIETIES have existed in all ages known to history and among all classes of mankind, except, perhaps, savages of the most primitive type. Such societies generally have clearly formulated purposes, with secret established procedures of initiation and ritual and with secret and overt signs and symbols. Although occasionally such societies admit both sexes, they have usually been limited to one sex, and secret societies for men have been more common than those restricted to women.

In the ancient world secret societies were chiefly religious, or at least professedly so, but in ancient times religious and temporal power were so closely associated that it was difficult, if not impossible, to draw a dividing line. There were the mysteries of Osiris and Serapis in Egypt, of Orpheus and Dionysus in Greece, of Cybele in Phrygia, and of Mithras in Persia, all of which tended to surround the worship of the gods with elements of secrecy and awe, which appealed to the conscience and imagination of men, and helped to keep the ignorant multitude in submission to the hierarchy and all that it represented.

In the Middle Ages the secret courts of Westphalia were practically vigilance committees, bound to secrecy by the very object of their existence. The Knights Templars were a secret order, although there is no trustworthy evidence that they were guilty of the practices alleged against them as a ground for suppression of the order and seizure of its wealth.

The Freemasons originated in the combinations formed by operative masons in the Middle Ages for self-protection while they were building cathedrals and other great structures. It is generally believed by students of antiquity that the origin of the order rests on a still more ancient body from which it sprung. (See also MASONIC FRATERNITY.)

The secret societies which have arisen within the 19th and 20th centuries have been chiefly political and benevolent. The struggle for freedom in Italy gave birth to powerful secret organizations, which continued to exist after Italian unity had been gained, and have caused, at times, much anxiety to the authorities. Ireland has also had a large number of secret political societies, including the United Irishmen, the Fenians, the Orangemen (qq.v.), and other orders of the past and present. In Russia the revolutionary society known as Nihilists (see NIHILISM) slew one czar and was an ever-present menace to autocratic government. In China secret societies have pervaded every class of the population; one of them, known as the Boxers (q.v.), caused the attack on the legations at Peking which provoked an international armed force to severe reprisals.

Modern secret societies in the United States have divided naturally into groups. Some have been concerned with political or semipolitical movements, as the Knights of Labor; others have been of religious character, as the Rosicrucians, and various alliances and leagues within the several denominations; others have fostered temperance or some moral issue, as the Good Templars; others have been fraternal, with important insurance features, as the Odd Fellows and Eagles; others have been approximately fraternal, as the Greek letter societies of the colleges; others have grown out of the trade alliances, as the ancient guilds and the modern trade union organizations.

The famous Tammany Society of New York, less generally known as the Columbian Order, dates from 1789, being only a fortnight younger than the republic itself. It was based on an earlier secret society, one of those bodies that had to be conducted largely in secret, which helped to develop the spirit that culminated in the American Revolution. Tammany is now wholly a political body within the Democratic Party. (See also TAMMANY HALL.) The Improved Order of Red Men (q.v.) developed from the same parent stock as Tammany, but along radically different lines of fraternity.

A notable development of the semipolitical secret society was the revival, in 1915, of the Ku Klux Klan (q.v.). While this movement started, and had its greatest strength in the South, its chief activities were not directed against Negroes, as in the case of its forerunner, but rather against Roman Catholics, Jews, and the foreign born. The organization gained great power in the southern and western states, and was a strong force even in the East. It was able to dictate nominations and elections in many cases. Its strength was greatest from 1922 to 1926. Dissensions in the body and revelations of corruption in politics, especially in Indiana in 1927, led to a weakening of its influence throughout the United States.

Of societies with evil purposes, the most noted has been the Mafia (q.v.), of Italy, which is said to have been introduced into the United

States with the large Italian immigration, and to which many crimes have been ascribed. The Molly Maguires were a society in the Pennsylvania coal regions, organized for the objects of terrorism and murder. It was suppressed by the State, and the leaders were executed. Consult Byrum, R. R., 'Secret Societies' (New York 1921); Lepper, J. H., 'Famous Secret Societies' (London 1932); Preuss, A., 'Dictionary of Secret and Other Societies' (Saint Louis 1924); Webster, N. H., 'Secret Societies and Subversive Movements' (New York 1925). See Societies, Criminal, and other secret societies under their respective titles.

SECRET SOCIETIES, College. See Greek Letter Societies.

SECRETARIAL EDUCATION. The distinction between the secretary and the stenographer is not sharp. The duties of the two frequently shade the one into the other. The stenographer of course has distinctive abilities. He knows some system of shorthand, he is a typist and he can transcribe his shorthand notes on the typewriter. The secretary, on the other hand, while he will find these abilities of the stenographer useful, will find that they are only a small beginning of what he needs. In fact the secretarial range of usefulness is very wide, too wide to be wholly comprehended in a single course of training. It is advisable to consider secretarial education under two heads, general or preparatory education and technical or special education.

Whether we have in mind the general or technical training it is necessary to classify the secretarial work. We may distinguish between the private or personal secretary and the institutional or organization secretary. The latter is a person who records the minutes of meetings of boards of trustees, boards of directors, committees, etc. This type of secretary needs very little technical training but should have a good general education. The private or personal secretary may be a social, educational, literary, political, ecclesiastical or business secretary, according as he serves a person engaged in any of these professions or occupations. The word secretary has its best application only in this sense, signifying a person who has charge of the *secreta* (secrets) of his employer.

Secretarial education presupposes a thorough high school or other secondary school course. After this preparatory training follows a liberal education with major emphasis on the particular field in view. The prospective social secretary gives major emphasis to philanthropy, history, art, literature. The prospective educational secretary centres his major interest on comparative education, educational administration, the philosophy of education, history of education, etc. The literary secretary must have literary taste, a knowledge of style and a wide acquaintance with the world's best literature. The political secretary will need thorough acquaintance with history, economics, sociology, law, etc. The ecclesiastical secretary must add to a liberal education a knowledge of church polity. The business secretary must lay emphasis on economics, geography, industrial history, commercial law, accounting, sociology and psychology. It is clear that the best results can be obtained only when the general education has consciously aimed at the particular field in which the secretarial duties are to be performed. Without such general education the secretary remains merely a clerk or a stenographer.

Secretarial education in its technical or specialized form should, therefore, be assigned to the last two years of the regular college course or, preferably, it should be a graduate course. With collegiate courses as a background, this technical training can be given in one or two years. It should offer the following features: Applied psychology, correspondence, business organizations, office management, filing systems, publicity methods, library methods, including cataloguing, business law, finance, stenography, typewriting.

History of Secretarial Education.— Business colleges have undertaken the training of secretaries but they have been unable to command the best standards of preparation or of training. They admit as students persons who have had less than a grammar school education. Their product is, therefore, defective in the use of English, frequently inaccurate in the use of ordinary office machinery, and wholly unprepared for the secretaryship as outlined above. The best business college product furnishes good material for stenographers.

High school commercial departments are rapidly entering this field. Their entrance requirements are higher and they give a broader training in language, history, science, etc., but they often fall short of thoroughness in the mechanics. That is, they give insufficient time to secure the necessary speed and accuracy in stenography and typewriting. The high school commercial product at its best approaches a secretarial standard but falls far short of the best conception of the secretaryship.

Both the business college and the high school commercial department are temporary means for meeting an ill-defined need. As the secretarial definition becomes clarified, the demand grows for a higher type of training. Colleges are adding secretarial courses and several universities are offering advanced courses in Business Administration. Among them are Simmons College, Harvard, Yale, New York University and others. A typical undergraduate secretarial college course is the following: *Freshman year:* English, French, German, history, hygiene, physics, filing. *Sophomore year:* English, French, German, history, penmanship, stenography, typewriting. *Junior year:* Business law, economics, English, stenography, typewriting, French, German, history, sociology. *Senior year:* Accounts, business methods, commerce, commercial teaching, economics, education, English, French, German, government, history, sociology, Spanish. A typical graduate course, open only to students who have already earned the bachelor's degree, is the following: Accounts, administration, business practice, stenography, typewriting, business law, library practice, commerce.

A. R. Brubacher,
Late President, State College for Teachers, Albany, N. Y.

SECRETARY-BIRD, or SERPENT EAGLE, a remarkable raptorial bird (*Serpentarius secretarius*) of South Africa, representing alone the family *Serpentariidæ*, associated

with the vultures. The general aspect of the bird is that of a long-winged, long-tailed, gray-and-black hawk mounted upon very long legs, so that as it stalks across a plain it might easily be mistaken for a crane. It runs with the speed of a horse and will fly when forced to do so, and may soar to a considerable height. It builds a big substantial nest in some bush or tree and reoccupies it from year to year. Their food consists of small animals and reptiles of all sorts, and especially of snakes, which it kills with a powerful forward kick, or, if the first stroke is not effective, repeats it with feet and knobbed wings, actively dodging the serpent's lunges, until the reptile is disabled or dead. These birds are frequently tamed and kept about the farmyard in South Africa as vermin destroyers. They take their name from the tufts of erectile feathers growing on each side of the head, which suggest a bunch of pens stuck behind a clerk's ear; the Arab name means «thirty ears.» Consult Evans, 'Birds' (New York 1900).

SECRETARY OF STATE, an officer whose business is to superintend and manage the affairs of a particular department of government. In the United States the Secretary of State has entire charge of foreign affairs, consular agencies and diplomatic matters. He is a member of the President's Cabinet and is usually considered the principal adviser to the chief executive. In Great Britain there are seven secretaries of state: for the Home, Foreign, Dominion, Colonial, War, Indian and Air departments. The Secretary of State for the Home Department has charge of the privy signet office; he is responsible for the internal administration of justice, the maintenance of peace in the country, the supervision of prisons, police, sanitary affairs, etc. The Secretary of Foreign Affairs conducts all correspondence with foreign states, negotiates treaties, appoints ambassadors, etc. The Dominion and Colonial Secretaries perform for their dependencies similar functions to those of the Home Secretary for the United Kingdom. The Secretary for War, assisted by the commander-in-chief, has the whole control of the army. The Secretary for India governs the affairs of that country with the assistance of a council. The Secretary of State for Air has supervision of all the governmental activities relating to aviation and its development. Each secretary of state is assisted by two under-secretaries, one permanent and the other connected with the administration, with numerous subordinates. There is no longer a chief secretary for Ireland. In 1885 the office of Secretary for Scotland was revived; he exercises in Scotland many of the powers and duties of the secretary for the home department, but has no cabinet rank by virtue of his office. The Secretary to the Admiralty is a subordinate member of the government, always a member of the House of Commons, in which he represents the Admiralty when the First Lord of the Admiralty is a peer. A secretary of embassy, or of legation, is the principal assistant of an ambassador or envoy.

SECRETION, the process whereby certain structures — glands or membranes — elaborate, separate or secrete, from the common medium presented by the blood, definite and specialized products destined either for use in the economy of the body, or for being sent out of the organism. In this way the process of secretion subserves a double function, or exhibits a double aspect, inasmuch as it not only manufactures products for home consumption, as it were, but provides also for the removal of waste matters from the body. Substances or products elaborated for the use of the organism are named secretions. Products secreted only to be discharged from the organism are called excretions. Take the liver and its bile as an example of a true secretion destined — primarily, at any rate — for use in the body, that is to say, in the process of digestion and elaboration of food; then as an illustration of the excretory form of the process, observe the kidneys and their secretions, these organs secreting from the blood urea, carbonic acid and other products which, in the form of urine, are destined to be discharged sooner or later from the body. The work of secretion is thus primarily seen to be among the most important of those actions the perfect performance of which contributes to the welfare of the organism; and interruption to the secretory processes results necessarily in the induction of disease of more or less serious kind. As both secretions and excretions are poured out from the secreting organ either upon the outer surface of the body or into some of its internal channels or ducts, it would appear that the two processes are identical in their ultimate aims and ends.

But true secretions (for example, bile and milk) consist of substances or compounds which, as such, do not exist in the blood, but demand a process of elaboration in the glands or secreting structures for their due and perfect formation. Excretions, such as the urine, consist of substances which exist in the blood in a form somewhat related to the final product. The elements are collected and thrown out more or less as such. Secretions exist *potentially* in the blood, and require for their elaboration definite and special structures. Excretions actually exist in the blood, and demand for their elimination and separation processes more analogous to mere filtering, and less complicated than those demanded by the work of secretion. This latter distinction receives practical confirmation and support from the fact that when excretions are checked in their natural discharge they may appear in their characteristic form in the blood. This result is well seen in cases of suppression of urine through disease or injury of the kidneys. But if true secretions be checked they cannot, under the same or ordinary circumstances, be detected in the blood; and removal of the secreting organ forever prevents the reappearance of the secretion. A pent-up secretion may be reabsorbed by the blood, and be detected in that medium, but this does not affect the grand distinction to be drawn between the actual nature of and differences between the two processes.

The essential structural characters of a secreting surface consist, firstly, of a structureless primary or basement membrane; secondly, of blood-vessels, which bring the blood from which the secretion is elaborated; and lastly, of cells or special structures devoted to the further elaboration of the constituents derived from the blood. A simple membrane, such as a serous or mucous membrane, exhibits the ar-

rangement of these elementary parts in its simplest phase; while more complicated arrangements of the same essential parts result in the formation of the more definite secreting parts which we term glands. Of these structures, in themselves constituting most of the chief organs or viscera of the body, three great plans may be distinguished, so far as the arrangement of their elementary parts is concerned. Thus the simple tubular glands — well exemplified in the tubular follicles of mucous membranes, in the gastric follicles or glands of the stomach, in the sweat or sudoriparous glands of the skin, etc.— consist of simple tubular involutions or depressions of the membrane which forms them, or with which they are connected. Each consists, therefore, of an open and elongated pouch or vesicle, the wall of which is composed of the primary membrane, while its lining is formed of secreting cells. This primary and elementary form of glands may be complicated by presenting a saccular rather than a merely tubular form, or by having the simple tube developed in a coiled form. The aggregated or conglomerate glands form the second division of gland structures. Such are the true mucous glands of the membranes of that name, the salivary and mammary glands, the prostate gland and the pancreas or sweetbread. These glands exhibit an essential structure composed of rounded clusters of vesicles termed acini, grouped together in various ways, which contain gland-cells, and which open by minute ducts gradually uniting to form the main duct of the gland. These acini or vesicles, as before, are lined by secreting cells. The third variety of glandular structures is that comprised in the idea of convoluted tubular glands. The kidney and the testicle exemplify this latter class of structures. In these glands we find tubules of basement membrane of generally uniform size, presenting a convoluted appearance, and terminating either in blind pocket-like extremities or by dilatations, as seen in the Malpighian corpuscles. (See Kidneys.) Sometimes, however, such tubular structures may, as in the testicle, form a loop, and then return along their original course. The tubules are lined by their secreting cells, and in their tortuosity evince a structure which presents a large secreting surface frequently comprised within a very small space or extent.

The exact means or rationale whereby each gland is enabled, from the common medium furnished to all, to elaborate through its own special cells its characteristic secretion, presents a problem from the perfect solution of which physiological science seems as yet far off. The cells of the liver contain bile; those of the mammary gland contain the fatty particles of the milk; and those of the testicle spermatozooids. But it can only be said that cells secrete; of the origin of these secreting powers and of the exact manner in which they are exercised nothing is known; yet that some acute and distinct specialization of the powers of secreting or gland-cells takes place over those of other and ordinary cells there can be no doubt whatever.

The view that secretion and the great process of nutrition (q.v.), to which secretion ministers, are identical is a reasonable and thoroughly consistent opinion. Viewed as mere organs, and apart from all purely functional considerations, the structure and formation of secreting glands might be regarded as simply processes of pure nutrition.

The greater the vascularity or blood-supply sent or distributed to any secreting organ the greater generally are its secreting powers. But the rate of circulation through a gland, or the mere quantity of the blood itself, cannot be shown to exert any direct influence on its secretory powers. Secretions may be retained for a lengthened period in some glands — such as the testicle — which are only periodically active, or they may be almost continually discharged, as is the case with the secretion of the kidneys. Under stimulation most if not all glands secrete more rapidly and abundantly, but the nature of the stimulation varies in different cases, or may be either of normal or abnormal kind. The discharge of secretions is effected by pressure from behind, while occasionally, as in the ureters and bile-ducts, the pressure of muscular fibres aids in the expulsion of secretions. The particular quality of blood may affect secretion, as at certain times a greater quantity of a particular material may be contained in the blood, the presence of this material stimulating the action of some appropriate gland.

The influence of the nervous system is important in connection with the general conditions of secretion, but much belonging to this topic exists in a still obscure state. It is known, however, that by regulating the supply of blood to a gland the nervous system may indirectly operate in preventing or forwarding the work of any gland, and that through the agency of conditions acting upon the nervous centres and upon the vegetative nervous system, effects are respectively wrought upon the glands. Food in the mouth induces a reflex action (q.v.), which action, produced through impressions made on nerve centres and reflected to the nerves of the salivary glands (q.v.) induces a copious flow of saliva through the stimulation of the glands. Mental conditions alone, and without material stimuli, will excite secretion, as seen in the flow of tears, or in the flow of saliva following the description of dainties; while the sudden stoppage of the milk secretion through fear or sorrow affords an illustration of the same fact. One secreting surface or gland bearing a functional relation to another gland (for example, kidneys and skin) may, through diminished or increased action, affect that other. Consult Bayliss, 'Principles of General Physiology' (2d ed., 1918).

SECTOR (Latin, *seco,* to cut), denotes in geometry that portion of the area of a circle included between two radii and an arc; or, a mixed triangle formed by the radii mentioned and the arc of a circle. Thus *A B C* contained within the radii *C A, C B,* and the arc *A B* is a sector of the circle of which the arc *A B* is a portion. The area of a circular sector is equal to the product of the arc of the sector by one-half of the radius. If the angle at the centre is given, the length of the arc of the sector may be found, since it is equal to π multiplied by the radius into the ratio of 180 degrees to the number of degrees of the sector. Thus:—

$S = \pi r \frac{n^\circ}{180^\circ}$, and $A = \pi r \frac{2n^\circ}{360^\circ}$,

for the area.

A spherical sector (the one just described is a circular sector) is a volume or solid that may be generated by revolving a circular sector about a straight line drawn through the vertex of the sector as an axis. The arc of the spherical sector generated the surface of a zone called the base of the spherical sector and the two radii generate the surfaces of the two cones, having a common vertex at the centre of the sphere. The *volume* of the spherical sector is equal to the zone which forms its base, multiplied by one-third of the radius of the sector.

Sector is also used as the name of an instrument employed in practical mechanics. It is sometimes called the sectorial scale of equal parts. It is usually a scale of wood, brass or ivory, consisting of two arms which open by turning round a joint or hinge at their common extremity. On each arm there is a diagonal line drawn through the point about which the arms revolve. These are divided into equal parts, which are numbered from the common point outwards.

The sectorial scale is so marked with lines of sines, tangents, secants, chords, etc., as to fit all radii and scales, and is useful in making diagrams: laying down plans, etc. Its principal advantage consists in the facility with which it gives a graphical determination of proportional quantities. It becomes incorrect comparatively, when the opening is great, or the result greater than the data. The sector is founded on the fourth proposition of the sixth book of Euclid, where it is proved that equiangular triangles have their homologous sides proportional.

This instrument is said to have been invented by Guido Uvaldi about 1568, though Gaspar Mordente of Antwerp describing it in 1584, attributes its invention to his brother Fabricius in 1554. It was described by several German and English writers in the same century, and again by Galileo, who claimed to have invented it in 1604. Frenchmen call it the compass of proportion.

Another instrument, used in astronomical observation, is called sector. A limb of this instrument embraces only a portion of a circle used for measuring differences of declination too great for the compass of a micrometer. This instrument was contrived for the purpose of measuring with great accuracy the zenith distances of stars, and when it is so employed it is called a zenith sector. It was by means of the zenith sector that Bradley discovered the existence and magnitude of two very important astronomical elements — the aberration of light, and the nutation of the earth's axis. The instrument has been at times used in trigonometrical surveys for determining the difference of latitude between two stations. For the difference of the zenith distances of the same star, observed at its meridianal passages at two places, gives the difference of the astronomical latitudes of such places without any regard to the star's declination.

There is yet another way in which the word sector is used. It sometimes denotes an arc-shaped attachment to an equatorial mounting often used for communicating the motion of the driving clock to the polar axis. A driving clock, obiter dicta, is a powerful and accurate clock motion used in astronomical and physical investigations to turn an equatorial telescope round its polar axis, so as to hold an object fixed in the field of view; or, for driving a chronograph or other instrument.

SECTS, Religious. See Religious Sects.

SECULAR GAMES, in Roman history, games celebrated at long and irregular intervals, and not, as their name would seem to indicate, once every century. Under the republic they were known as the Tarentine games, from a place in the Campus Martius, called Tarentum, where they were celebrated, and appear to have been instituted about the time of the consul Valerius Publicola. Nothing is known of their origin beyond the fact that they were celebrated in honor of Pluto and Proserpina for the purpose of averting from the state some great calamity. Under Augustus they were revived in 17 B.C. with considerable pomp, occupying three days and nights, and being accompanied by sacrifices to Jupiter, Juno and all the superior deities. For this occasion Horace wrote his 'Carmen Sæculare' in honor of Apollo and Diana, sung by a chorus of youths and virgins. The secular games were celebrated on subse quent occasions, namely, in the reign of Claudius in 47 A.D., in that of Domitian in 88, and in that of Philip in 248, exactly 1,000 years after the building of Rome.

SECULARISM, an ethical system founded on the principles of natural morality and independent of revealed religion or supernaturalism. Its first postulate is freedom of thought — the right of every man to think for himself: this is now admitted, at least in theory, by most Christians; but it was not so when the platform of Secularism was first promulgated about the year 1846 by George Jacob Holyoake in England. Implied in this postulate as its necessary complement is the right to difference of opinion upon all subjects of thought. And this right would be nugatory without the right to assert that difference. Finally, Secularism asserts the right to discuss and debate all vital questions, such as the commonly received opinions regarding the foundations of moral obligation, the existence of God, the immortality of the soul, the authority of conscience, etc. Secularism does not maintain that there is no other good but the good of the present life: with that question it does not meddle: but it does maintain that the good of the present life is a real good, and to seek that is good; and it aims to find "that material condition in which it shall be impossible for man to be deprived or to be poor." In this life there are, it asserts, material agencies which cannot be neglected without folly or hurt, and that it is "wisdom, mercy and duty to attend to them." It does not combat the pretensions of Christianity; does not say there is no light or guidance save in nature; but maintains that "there is light and guidance in secular truth, whose conditions and sanctions exist independently, act independently, and act for ever."

SECULARISTS. See Religious Sects.

SECURITIES AND EXCHANGE COMMISSION (SEC), The, a federal agency responsible for administration of the following laws designed for the protection of the investing public: Securities Act of 1933; Securities Exchange Act of 1934; Public Utility Holding Company Act of 1935; Trust Indenture Act of 1939; Investment Company Act of 1940; and Investment Advisers Act of 1940. The commission also serves as adviser to federal courts in corporate reorganization proceedings under chapter 10 of the National Bankruptcy Act.

The commission is composed of five members appointed by the president with the advice and consent of the Senate, not more than three of whom may be of the same political party. They serve for five-year staggered terms.

The Securities Act requires the prior registration with the commission of securities offered for public sale. The purpose of registration is to provide disclosure of financial and other information concerning such securities on which an investor may make an informed judgment as to their worth. To that end, a prospectus containing the pertinent disclosures must be furnished prospective investors. Indentures under which large debt issues are issued must also be qualified under the Trust Indenture Act.

The Securities Exchange Act requires similar disclosures in respect of securities listed for public trading on our national securities exchanges. Issuers of such securities also must make certain minimum disclosures in the solicitation of proxies from the holders of listed securities; and management officials as well as large stockholders must report their stock holdings and transactions and may be accountable to the company for short-term trading profits therein.

The securities laws prohibit misrepresentation, manipulation and other fraudulent acts and practices, and empower the commission to investigate securities violations and enforce statutory sanctions. The Securities Exchange Act also provides a system for regulation of the trading practices on the exchange and over-the-counter markets, designed to establish and maintain just and equitable principles of trade. As an incident thereto, national securities exchanges and over-the-counter brokers and dealers must register with the commission and conform their business practices to prescribed standards designed for the protection of investors. Securities violations may lead to injunction or criminal prosecution or, in the case of brokers and dealers, revocation of registration.

The Public Utility Holding Company Act of 1935 provides for special regulation of financial and related practices of electric and gas utility holding company systems (and calls for integration of their properties and simplification of their corporate structures); while the Investment Company and Investment Advisers acts provide for special regulation of the activities of investment companies and investment advisers.

SEDALIA, city, Missouri, and Pettis County seat; altitude 907 feet; 185 miles west of St. Louis, 98 miles southeast of Kansas City; on the Missouri Pacific; and the Missouri-Kansas-Texas railroads. Located at the center of its county, and a little to the west of the center of the state, Sedalia is the focal point for several divisions of the railroads that serve it with freight and passenger transportation, and is important as shipping and distributing center for an extensive productive area surrounding the city. Large railroad shops are located here, employing many of the city's workers.

Situated in the midst of an agricultural region in which corn, wheat, and oats are the principal crops, Sedalia has a list of industrial activities which includes the processing of dairy and creamery products; with a schedule of manufactures that carries such items as disinfectants, work clothes, brooms, glass blocks, prefabricated houses, trailers, shoes, and mattresses. Besides the railroad shops there are, in the heavier industries, flour mills, packing plants, and bottling works.

There are excellent public and parochial schools, and a Carnegie Library. Musical organizations include a men's choral club and a symphony orchestra. Prominent among the buildings of the city are the Courthouse, City Hall and Armory; the library, banks, churches, and the state fair buildings. The Missouri State Fair is held here annually, in August, under the supervision of the State Department of Agriculture.

History.—First permanent settlement on the Sedalia site was made in 1860. The land, held by Gen. George R. Smith, a resident of the county, having been acquired by him in 1856, was set aside for development in anticipation of the coming of the railroad. In 1857 a plat of the proposed town was filed; with more heed for geometrical precision than for the possible civic requirements of the future, it was laid out in a square. It is said the founder first settled upon the name Sedville, and later changed it to its present form. The first passenger train came in 1861, the year after settlers had established themselves. The westward advance of the railroad was delayed after the outbreak of the Civil War, and for several years Sedalia was its western terminus. During the entire period of the Civil War, Sedalia became a military post, which it remained until the latter part of 1864. The town was held by the North, except for a single day when raiding Confederate forces had possession of it; Union forces under command of Gen. A. J. Smith recovered the city. In 1861, when operations in Missouri were under way, Gen. Nathaniel Lyon and Gen. John C. Fremont fitted out forces at Sedalia. After the war years the extension of the railroads brought to Sedalia a commercial activity that has endured. Sedalia became county seat in 1864, replacing the original seat of Georgetown. It was chartered as a city in 1889. The city has government by mayor and council. In 1880 the population was 9,561; in 1890, 14,068. Pop. (1940) 20,428; (1950) 20,269.

SEDAN, sē-dăn′, town, France, in the Department of Ardennes, near the Belgium frontier, on the Meuse River, 11 miles east-southeast of Mézières, and about 160 miles northeast of Paris. Its principal buildings are the theater, public library, and college. The town has important cloth manufactures, employing the majority of the inhabitants. Its chief interest is connected with the defeat of the French Army by the Germans, and the surrender of Napoleon III with 100,000 soldiers, Sept. 2, 1870. During the final campaign of World War I, American troops occupied the heights dominating the city on Nov. 6-7, 1918, but for sentimental reasons it was placed within the French area, so that they should be the first to enter the town. In World War II it was

taken by the Germans in May 1940 and held until retaken by Americans in August 1944. Pop. (1946) 18,359.

SEDAN, sē-dăn', or **SEDAN CHAIR.** A portable chair, cushioned and decorated, used as a vehicle for carrying one person who sits within it, the enclosure being therefore of much greater height than width. It is carried on two poles which pass through rings secured to the sides, usually by two bearers. They were introduced in western Europe in the 16th century, but their use was extended greatly in the 18th century, when they were the common means of transportation for ladies and gentlemen in England and France. Similar chairs carried on the shoulders of two or more bearers have been long in use in China.

SEDDON, sĕd"n, **James Alexander,** American statesman: b. Falmouth, Va., July 13, 1815; d. Goochland County, Va., Aug. 19, 1880. He was graduated from the law school of the University of Virginia and practiced law in Richmond. He was a Democratic member of Congress 1845–1847 and 1849–1851, after which he retired to his estate. In February 1861 he was one of five delegates to the "Peace Congress" at Washington, where he maintained the right of a state to peaceful secession. In July 1861 he was a delegate from Virginia to the Confederate provisional congress, and in November 1862 became secretary of war in the Confederate Cabinet. This position he held until the Civil War was nearly over, resigning Jan. 28, 1865, and retiring from public life.

SEDDON, Richard John, New Zealand premier: b. Eccleston, Lancashire, England, June 22, 1845; d. at sea, June 10, 1906. Emigrating to Australia at 18 he was attracted to New Zealand four years later by the gold discoveries. He sat in the New Zealand Parliament in 1879–1881 and 1881–1890; later he became minister for defense and public works, commissioner of trades and customs, and finally rose to be premier. By profession he was a mining engineer, and he was an associate of the American Institute of Mining Engineers. He was the body and the soul of the New Zealand government.

SEDGE, a common term indiscriminately applied to the many marshy plants of the family Cyperaceae, and particularly to the genera *Cyperus* and *Carex*. The sedges are grasslike or rushlike herbs with slender stems, generally solid, often triangular, and but rarely swollen at the nodes. The leaves are pointed and narrow (the word "sedge" refers to their cutting edges), with closed sheaths, with or without reduced ligules, and are three-ranked. The flowers are either perfect or otherwise, and are very small, having a hypogynous perianth, generally consisting merely of bristles or scales, with from one to several stamens having slender filaments, and a simple, toothed or cleft style. The fruits are one-celled and are lenticular or three-cornered. The tiny grasslike flowers are gathered into spikelets of one or more, each (or rarely a pair) in the axil of a scale, which may be persistent or deciduous; the spikelets are themselves arranged in various inflorescences, often in conspicuous umbels. The sedges frequent marshy lands, chiefly, and are occasionally useful in binding sea-sands or in contributing to the growth of peat-bogs.

SEDGWICK, Adam, English geologist: b. Dent, Yorkshire, March 22, 1785; d. Cambridge, Jan. 27, 1873. He was graduated at Trinity College, Cambridge, in 1808, became a fellow there in 1810 and in 1816 was ordained in the Anglican Church. Because of general high ability he was appointed professor of geology at Cambridge in 1818, a chair hitherto something of a sinecure. Sedgwick, however, set at once about acquiring a knowledge of geology that enabled him to raise the chair to one of importance in the university: was one of the founders of the Cambridge Philosophical Society in 1819, through which he greatly assisted the development of the study of natural science; and labored indefatigably to augment the geological collections of the university, often at his personal expense. He continued his duties as a clergyman and made important geological investigations in Wales, Yorkshire, Devonshire, the Lake Country, the Isle of Wight and northern Scotland. He founded the Cambrian and the Devonian systems; but was for long engaged in a controversy with Murchison, whose Lower Silurian system overlapped Sedgwick's Upper Cambrian system. The matter was disputed until the substitution of the term Ordovician after Sedgwick's death. He was president of the Geological Society in 1829–1830, and was awarded its Wollaston medal in 1851. He was also awarded the Copley medal of the Royal Society in 1863. As a memorial to him the Sedgwick Museum was opened at Cambridge in 1903. Author of *Geological Relations and Internal Structure of the Magnesian Limestone* (1828); *Discourse on the Studies of the University of Cambridge* (1833); *Synopsis of the Classification of the British Palaeozoic Rocks* (1855), etc. With Sir Roderick Murchison he wrote *Physical Structure of the Rocks of Devonshire* (1839).

SEDGWICK, Anne Douglas (Mrs. Basil de Selincourt), American novelist: b. Englewood, N. J., March 28, 1873; d. Hampstead, Eng., July 21, 1935. She left the United States when a child and lived chiefly in Paris and London. She studied painting in Paris but later turned her attention to literature. She was married in 1908. Author of *The Dull Miss Archinard* (1898); *The Rescue* (1902); *Paths of Judgment* (1904); *A Fountain Sealed* (1907); *Tante* (1911); *The Nest* (1912); *The Little French Girl* (1924); *The Old Countess* (1927); *Dark Hester* (1929); *Philippa* (1930).

SEDGWICK, Ellery, American author: b. New York, Feb. 27, 1872. He was graduated at Harvard University in 1894 and taught at Groton School, Massachusetts, 1895–1896. He was on the editorial staff of the Worcester *Gazette* 1896 and *The Youth's Companion* 1896–1900; and from 1900–1905 was the editor of *Frank Leslie's Popular Monthly*. After a brief connection with *McClure's Magazine* and with Messrs. D. Appleton and Company, he became editor of the *Atlantic Monthly* and president of the company 1909–1938. In 1915 he was elected member of the National Institute of Arts and Letters. He has published *Life of Thomas Paine* (1899); *The Happy Profession* (1946).

SEDGWICK, Henry Dwight, American lawyer and author, brother of Ellery Sedgwick (q.v.): b. Stockbridge, Mass., Sept. 24, 1861. He

was admitted to the bar in 1884 and was engaged in practice in New York in 1885–98. He has since been occupied with literary work. Author of 'Letter of Father Cuellar' (1896); 'Life of Father Hecker' (1897); 'Life of Samuel Champlain' (1901); 'Life of Francis Parkman' (1904); 'The New American Type' (1908); 'Italy in the Thirteenth Century' (1912); 'An Apology for Old Maids' (1917); 'Dante' (1919); 'A Short History of France' (1928).

SEDGWICK, John, American soldier: b. Cornwall, Conn., 13 Sept. 1813; d. Spottsylvania C. H., Va., 9 May 1864. He was graduated at West Point in 1837 and served in the army from that time until his death, taking prominent part in three wars and in many engagements against the hostile Indians in the West. During the second Seminole War in Florida 1837–38, he was second lieutenant of artillery, was promoted in 1839, and took part in the Mexican War 1846–47, receiving promotion for gallantry after Churubusco and after Chapultepec. When the Civil War began he became lieutenant-colonel of artillery and rose to the rank of major-general. Stationed first at Washington, he was afterward commander of brigade, then of division in the Army of the Potomac, being placed in command of the Sixth army corps in 1863. He took part in the battle of Fair Oaks, the Seven Days' Battles; was severely wounded at Antietam, and after a leave rejoined the army in time for Chancellorsville and Fredericksburg. He played a distinguished part at Gettysburg, and in 1864 participated in the battles of the Wilderness and Spottsylvania, at which latter place he was shot by a Confederate sharpshooter during a movement of his troops. A bronze statue of him was erected at West Point in 1868. His death forms the subject of a painting by Julian Scott, now in the public library at Plainfield, N. J.

SEDGWICK, Robert, American colonist and soldier: b. Woburn, England, about 1590; died Jamaica, West Indies, 24 May 1656. He emigrated to Charlestown, Mass., in 1635, being one of the first settlers there; in 1638 he assisted in organizing the Ancient and Honourable Artillery Company of Boston (having received his training in the Artillery Company of London), and two years later became its captain. He rose to the command of the militia, in 1652. With John Winthrop, Jr., he helped establish, in 1643, the first iron works of the United States. Under Cromwell's orders he captured several French ports in the Penobscot region and in 1655 assisted in the capture of Jamaica. Cromwell raised him to the rank of major-general and made him governor of that island.

SEDGWICK, Theodore, American jurist and legislator: b. Hartford, Conn., May 1746; d. Boston, 24 Jan. 1813. He studied at Yale, was admitted to the bar in 1766, began practice at Great Barrington, Mass., and soon removed to Sheffield, where he attained eminence in professional and civil affairs, frequently representing the town in the Massachusetts legislature. At the beginning of the Revolution he entered the Continental army, serving on Gen. John Thomas' staff in the expedition to Canada, and later acting unofficially as commissary. In 1785–86 he was in the Continental Congress, and in the winter of 1787 was prominent in the suppression of Shays' rebellion (q.v.). He was speaker of the State house of representatives in 1788, and in that year also a member of the State convention for the ratification of the Federal Constitution; from 1789 to 1796 a representative in Congress; and in 1797–99 United States senator, being president pro tem. in 1797. Then he was again in the House, and its speaker until 1801. From 1802 until his death he was a justice of the Supreme Court of Massachusetts, being noted on the bench for the clearness of his opinions. He was one of council who secured a decision (1780) by which such a construction was given to the constitution of Massachusetts as to abolish slavery in that State. He was an active Federalist, and a member of the American Academy of Arts and Sciences.

SEDGWICK, Theodore, American author, son of Theodore Sedgwick (q.v.): b. Albany, N. Y., 27 Jan. 1811; d. Stockbridge, Mass., 9 Dec. 1859. He was graduated at Columbia College in 1829, and was admitted to the bar in 1833. He was attache at the United States legation at Paris in 1833–34, and afterward practised law in New York until 1850. From 1858 until his death he was United States district attorney of the southern district of New York. Author of 'Memoir of William Livingston' (1833); 'What is Monopoly?' (1835); 'Treatise on the Rules Which Govern the Interpretation and Practise of Statutory and Constitutional Law' (1857; 2d ed., 1874), etc. He edited the political writings of William Leggett (2 vols., 1840).

SEDGWICK, William Thompson, American biologist: b. West Hartford, Conn., 29 Dec. 1855; d. 26 Jan. 1921. He was graduated from the Sheffield Scientific School of Yale University in 1877 and later studied at Johns Hopkins University. He was an instructor at the former 1878–79; was at Johns Hopkins as a Fellow in biology 1879–80; as instructor and associate professor of biology at the latter also 1880–83. After 1883 he was professor of biology in the Massachusetts Institute of Technology. He was biologist for the Massachusetts State Board of Health 1888–96. He is a joint author of 'General Biology' (1886); and published 'The Principles of Sanitary Science and Public Health' (1902); 'The Human Mechanism' (1906).

SEDILIA, *in architecture,* originally the rows of seats in a Roman amphitheatre. Later applied to the stone seats on the south side of the altar in Roman Catholic churches; used by the priest, deacon and sub-deacon in the intervals of the church service. In cathedrals a row of such seats is provided for the clergy.

SEDIMENTARY ROCKS, as originally applied, a term used to indicate those deposits or sediments laid down by water, as contrasted with those rocks which have solidified from a fluid condition and known as igneous. The term has been somewhat expanded in recent usage, to include also the deposits formed by wind and those made by glaciers. They may be divided on the one hand into those laid down in the sea (marine), and those formed on land (terrestrial or continental). On another basis they are divided into aqueous, eolian and glacial. On still another basis they may be considered as of mechanical, chemical or

organic origin. The most familiar types are consolidated gravels, conglomerates; consolidated sands, sandstones; consolidated clay, shales; and consolidated marls or lime oozes, limestones. For a more detailed account of these rocks and the methods by which they are formed, see SHALE, SANDSTONE, and the section on *Sedimentary Rocks* in the article on ROCKS.

SEDITION, an offense short of treason but more serious than ordinary breach of the peace, or conduct tending thereto. Sedition, as a distinct offense, is unknown to English law, and is also unknown to United States laws, save in acts of Congress relating to the army and navy, and there it evidently means a mutiny or uprising against superior authority, for it is provided that a soldier joining any sedition, or who being present at a sedition does not do his utmost to suppress the same, shall be punished with death, while a sailor uttering seditious words can be punished at the discretion of a court-martial. State laws relating to sedition treat it as a minor offense, to be punished when it amounts to an actual attempt, whether in speaking or writing, or by actual violence, to agitate the overthrow, by unlawful means, of established authority. Anarchist meetings are within this description; when they lead to riot and murder, moreover, as in the case of the Haymarket Riot, in Chicago, the offense is more serious, and all parties concerned are held as principals or accessories to the crimes which result directly from their course of action.

The Alien and Sedition laws enacted by Congress in 1798 embodied an extension of the meaning of sedition which the majority of the American people evidently did not approve, and were aimed at freedom of speech and of the press. The motive for these laws was the suppression of the revolutionary tendencies excited by the French Revolution, the Republican (afterward called the Democratic) party sympathizing with the Revolution, and the Federalists being adverse at least to the extreme phases of that great convulsion. Several prosecutions under the Sedition Law served to make it more odious, and the censequence was the retirement of the Federalist party from power, and the election of Thomas Jefferson to be President of the United States. Since that time, except during the Civil War, no attempt has been made to interpret as sedition the editorial utterances of the press regarding current events. See ALIEN AND SEDITION ACTS.

SEDITION LAWS. See ALIEN AND SEDITION ACTS.

SEDLEY, sĕd'lĭ, SIR **Charles,** English poet, dramatist and wit: b. Aylesford, Kent, 1639; d. 20 Aug. 1701. He was educated at Oxford, but did not graduate. He wrote comedies and songs; of the latter one or two are still popular, but the former are unequal to his reputation. His first comedy, 'The Mulberry Garden,' partly founded on Molière's 'École des Maris,' was published in 1668; and among his other works of this class are 'Bellamira or The Mistress' (1687), based on the 'Eunuchus of Terence,' and 'The Grumbler.' In later life he entered Parliament and took an active part in politics, uniformly opposing the unconstitutional policy of James II, and was one of the chief promoters of the Revolution.

SEDRAT, the name given in the religious lore of the Mohammedans to the lotus tree, standing on the right-hand side of the invisible throne of Ali, with two rivers running from its roots. Its boughs extend farther than the distance between heaven and earth, while numberless birds sing among them, and countless angels rest beneath their shade.

SEDUCTION, *in law,* the act of wrongfully persuading a woman, as by promise of marriage, to surrender her chastity. The theory of this offense in English law is that it is not against the seduced person but against the parent or person standing in that relation, who may sue for damages for actual loss of services caused by such seduction. If this be proved, he can recover not only any pecuniary loss he may have sustained but also compensation for injury to his feelings and damages by way of punishment of the offender. Very slight evidence of service is sufficient to establish the relation of master and servant and to fix the defendant's liability. The action is usually brought by the father, but it may be brought by any person who stands in the relation of master to the seduced person. Usually the woman cannot sue in her own name, but in Scots law she may do so if the deceit of the defendant has been the sole cause of the injury. The action, as a rule, can be brought only in behalf of an unmarried woman, the seduction of a wife being known as criminal conversation, but in England it was formerly held that an action might be brought by the father of a married woman living in his house separated from her husband and giving even the slightest services to her parent. By statute, however, the husband can now demand damages in a suit for divorce where the seducer is corespondent. While the rule in England is that the parent cannot sue if the daughter is not performing at least slight services for him, this has been modified in the United States to the extent that the parent may bring action if he is entitled to her services during minority, whether she is in his service or not. Statutes in the United States have greatly modified the old common-law rule. For instance, seduction was not a crime at common law, but in many of the States it has been made so by statute if the woman seduced was previously chaste, particularly when accompanied by a promise of marriage. Likewise in some States the seduced woman may bring the action in her own name and may have both a criminal and a civil remedy.

SEDUM, a genus of plants of the family *Crassulaceæ,* the many species of which inhabit chiefly the north temperate and Arctic zones. They have succulent, generally smooth foliage, of varying form, but often crowded on the stems, and four or five parted flowers, with distinct petals, usually in cymose inflorescences and of pink or yellowish hue. The carpels of the fruit are separate or united at the base. The sedums are pre-eminently useful for rock-gardens, and for cultivation in plots or in poor soil, since they are remarkably hardy under adverse conditions. Some prefer barren rocks, and spread luxuriantly over them, thus earning their common name of stone-crop. Like the house leeks (*Sempervivum*), which they closely resemble, they are easily propagated by seeds

or offshoots, and are possessed of great vitality. *S. telephium* is the orpine (q.v.), a live-for-ever, or live-long, so called because a cut branch, fastened out of doors, will grow, and perhaps bloom, drawing upon the store of reserve tissue in its fleshy bulk, and since it will occasionally start into growth when pressed and dried it is also called Aaron's rod. This species was further known as Midsummer men, as it was used for love-charms on midsummer's night, two stems of it being set up to see if one, representing a lover, would turn to the other. *S. acre,* the English wall-pepper, is a common creeping plant covered with yellow, star-like flowers, fond of sunny, rocky places, and is an emetic and cathartic. One of the handsomest species is the old-fashioned border plant, *S. spectabile,* with upright stems and broad cymes of purplish flowers. *S. telephioides* and *S. roseum,* the rose-root or rhodia of old time shops, with rose-scented roots, make themselves conspicuous by growing in great masses on mountain ledges. *S. album* was formerly used as a medicine, and cooked or eaten as a salad under the name of worm grass or prickmadam.

SEE, Horace, American naval engineer: b. Philadelphia, 17 July 1835; d. 1909. He received his training as a mechanical engineer in a machine shop. As superintendent engineer of the firm of William Cramp and Sons he was identified with its fame as the builder of high-class ships. He is known as the inventor of the hydropneumatic ash ejector, the cylindrical mandrel for face bearings and other important mechanical devices. He was consulting engineer and naval architect for several noted corporations in the United States.

SEE, Sir **John,** Prime Minister of New South Wales: b. Felling, Huntingdonshire, England, 1844; d. 1907. In 1853 he went to Australia, and in 1880 was elected member of the colonial Parliament, to which he was re-elected several times as member for Grafton until 1904. In 1885 he was appointed Postmaster-general and from 1891 to 1894 was Treasurer. In 1899–1901 he held the portfolio of Chief Secretary and Minister of Defense, and from 1901 to 1904 was Prime Minister. In 1902 he was knighted. Ill health compelled his retirement in 1904.

SEE, Thomas Jefferson Jackson, American astronomer and mathematician: b. on a farm near Montgomery City, Mo., 19 Feb. 1866. In 1884 he entered the University of Missouri and was graduated (A.B., L.B., S.B.) at the head of his class in 1889, with the Missouri astronomical medal for an original thesis on the 'Origin of Binary Stars.' He at once entered the University of Berlin, for post-graduate study, and won with high honors the degrees of A.M., Ph.D., 10 Dec. 1892 Upon returning to America 25 Dec. 1892, he organized and had charge of the department of astronomy at the University of Chicago, and aided in establishing the Yerkes Observatory, 1894. In 1896 Dr. See entered upon a survey of southern double stars and nebulæ for the Lowell Observatory. During two years at Flagstaff, Ariz., and at the City of Mexico, he examined with a 24-inch telescope some 200,000 fixed stars, between 15 and 65 degrees south declination, and discovered some 600 new double stars, besides measuring about 1,400 stellar systems previously reorganized by Sir John Herschel and other observers. Dr. See lectured on Sidereal Astronomy at Lowell Institute, Boston, in December-January, 1898–99, and was immediately afterwards appointed professor of mathematics, United States Navy, by President McKinley. On duty at the Naval Observatory, Washington, 1899–1902, with 26-inch telescope, he observed double stars and satellites, and measured the planets and satellites by daylight and at night, thus deducing the absolute diameters and constants of irradiation of the chief bodies of the solar system. On duty at the Naval Academy, 1902–03; since in charge of the Naval Observatory, Mare Island, Cal. During 1902–03, he investigated the position of Laplace's "Invariable Plane of the Solar System"; and during 1904–06 carried out important researches on the moments of inertia, internal densities, pressures, temperatures and rigidities of the heavenly bodies, earthquakes, etc. He has made numerous other researches in regard to the origin of the solar system, the cause of the land and water hemispheres of the terrestrial globe, gravitation, etc.

He has published 'Die Entwickelung der Doppelstern-Systeme' (Berlin 1893); 'Researches on the Evolution of the Stellar Systems' (Vol. I, Lynn 1896); Vol. II, 'Capture Theory of Cosmical Evolution' (1910); 'Researches on the Physics of the Earth' (in Proc. Am. Philos. Soc. 1906–13); 'Dynamical Theory of the Globular Clusters' (in Proc. Am. Philos. Soc., 1912); 'Electrodynamic Theory of Magnetism and of Universal Gravitation: Discovery of the Cause of Gravitation, with proof that this fundamental force of nature is propagated with the velocity of light' (1915); 'Determination of The Physical Cause which has established the Unsymmetrical Equilibrium of the Solid Nucleus in the Fluid Envelope and thereby produced the well defined land and water hemispheres of the Terrestrial Spheroid' (in *Astrom. Nachr.,* Vol. 202, Kiel 1916); 'Eighth and Ninth Mathematical Memoirs on the New Theory of Aether' (1925–27).

SEE, a word applied to the seat or throne of a bishop, but more usually employed as the designation of the city in which a bishop has his residence, and frequently as that of the jurisdiction of a bishop, that is, as the equivalent of diocese. The Holy See is located in Rome.

By universal usage, see designates the city (thence, at least in popular language, the entire diocese) in which the seat of the bishop is placed. Sees have, as a rule, been in some city, or considerable town, and in general the name of a see is taken not from the district governed by the bishop but from the city or town. To this usage, the names of most of the Protestant Episcopal sees in America are an exception. Sees *In Partibus Infidelium* were those which retained their ancient names, though in many cases not merely the cities themselves, but even all traces of the Christian religion, in the sites on which they anciently stood, have disappeared. In the Roman Catholic Church, the Pope alone establishes sees, and alters their distribution and their local limits and boundaries; though

these changes are not made except in extreme cases without consent of the actual bishop. In the Church of England, all changes in dioceses, such as in their limits or boundaries, are done by authority of Parliament. In the United States, the General Convention of the Protestant Episcopal Church creates new sees and changes limits of diocese.

SEEBACH, zā'bäĸ, **Marie,** German actress: b. Riga, Latvia, Feb. 24, 1829; d. St.-Moritz, Switzerland, Aug. 3, 1897. She first appeared as a dramatic actress in Hamburg in 1852, and her fame was established two years later when she played various classical roles under the director Franz von Dingelstedt in Munich. She was married to the noted Wagnerian tenor Albert Niemann in 1859, but their marriage ended in divorce nine years later. In 1866 she became a member of the company of the Royal Theater in Berlin. She was distinguished for her performances in Shakespearean tragedy and in Goethe's *Faust* and *Egmont.*

SEEBOHM, sē'bōm, **Frederic,** English economic historian: b. Bradford, England, Nov. 23, 1833; d. Hitchin, Feb. 6, 1912. He was active in civic affairs, became a barrister in 1856, but devoted much of his attention to the study of the social organization of the Saxon, Celtic, and early English tribes. His publications include *The English Village Community* (1883), *Tribal Custom in Anglo-Saxon Law* (1902), *The Tribal System in Wales* (1895), and *Customary Acres* (1914).

SEECKT, zākt, **Hans von,** German soldier: b. Schleswig, Germany, April 22, 1866; d. Berlin, Dec. 27, 1936. After a succession of military posts he became chief of staff, in 1915, of the eastern armies under August von Mackensen. During 1917–1918 he served as chief of the general staff of the Turkish field army, and from 1918 to 1926 was commander in chief of the Reichswehr. He later helped reorganize the Chinese Army and served as an adviser to Chiang Kai-shek from 1932 to 1935.

SEED, Miles Ainscough, American inventor and manufacturer: b. Preston, England, Feb. 24, 1843; d. Pelham, N. Y., Dec. 4, 1913. He was educated in English public schools, and early undertook experiments in photography. In 1865 he came to the United States, and settled in St. Louis, Mo. For a period of years he was chief operator and manager of the photographic gallery of John Scholton. After perfecting a method for the manufacture of photographic dry plates, he established the M.A. Seed Dry Plate Company at St. Louis (1882), and manufactured the product. The plate was the first one suitable for X-ray and astronomical purposes. The company also introduced positive celluloid films, and produced other films and plates. The business and Seed's formulae were sold in 1902 to the Eastman Kodak Company, Rochester, N. Y. For five years thereafter, until his retirement, Seed was a special advisor to the company.

SEED PLANTS, or **SPERMATOPHYTES,** exceed in importance all other plants, since they are more effectively adapted to a land habitat than any other plants. They consist of two main classes, Gymnosperms and Angiosperms. In the Gymnosperms (naked-seeded plants), the seeds are borne on the surface of the carpel or cone scale. These are all woody, perennial forms and, with few exceptions, are evergreens. They are of great economic importance as sources of timber and resinous materials such as turpentine. They are a relatively small group, about 500 species. In the Angiosperms (covered-seeded plants), the seeds are formed within a closed structure, the ovary. There are more than 130,000 species of Angiosperms, a greater number than in any other class of plants. They include most of the species utilized by man as sources of food, clothing, medicines, and industry. Angiosperms are further divided into two classes, monocotyledons and dicotyledons. Monocotyledons possess: embryos with only one cotyledon, which is terminal; vascular bundles scattered throughout the stele in the stem; closed venation in leaves; flowers with the flowering parts in cycles of three. Grasses, including the important grains such as corn, wheat, and rice, are examples of this class. Dicotyledons possess: embryos with two lateral cotyledons; arrangement of vascular bundles in a ring in the stem; open venation of leaves; cycles of four or five in the flowering parts. A large proportion of our vegetables, flowers, and deciduous trees belong to this class. See also PLANTS AND PLANT SCIENCE—*Classification, Morphology, and Evolution* (Seed Plants).

SEEDS, the reproductive structures of seed plants. Developed from ovules, they consist of the *embryo* (rudimentary plant), *endosperm* (stored food in varying amounts and sometimes lacking), and the coats which form the protective layers on the surface. The embryo is the most essential part of the seed, consisting of the *plumule*[1] (the rudimentary stem), the cotyledon or *cotyledons* (seed leaves), the *hypocotyl* (the portion connecting the cotyledons and the radicle), and the *radicle* (rudimentary root). The embryo varies greatly in size and form in different seeds. For example, when the bean seed is mature the embryo fills the seed, while in the case of orchids or American holly the embryo is just a mass of undifferentiated cells at the time of seed maturity. At germination (sprouting), the plumule develops into the shoot, and the radicle into the root. The cotyledons may or may not appear above ground. In some cases, they function as real leaves, turning green and carrying on photosynthesis for a while. In the hypocotyl region of the embryo axis, the transition from stem to root tissues of the new plant takes place.

Seed formation usually follows fertilization of the egg nucleus of the ovule by a male nucleus from the germinating pollen grain, the fertilized ovule developing into the embryo of the seed. The endosperm, or stored food for the young embryo, develops after the conjugation of a second male nucleus from the pollen tube with two other nuclei in the embryo sac. This double fertilization occurs in most Angiosperms, but the resulting endosperm is not always present in the mature seed since it may be used up by the embryo in its development as in the case of many legumes. In the Gymnosperms, the endosperm tissue is entirely gametophytic, being produced by the ovule without any fertilization.

[1] Sometimes called *epicotyl.*

Although seed formation is usually dependent upon a fertilization process, seeds may be formed from certain parts of the ovary normally considered as purely vegetative. Such seeds, containing both embryo and endosperm, are formed by the dandelion, for example. Development of seeds without fertilization is known as *apomixis.*

Seeds, the ripened ovules of flowers, are usually contained in fruits that develop from ovaries. If the fruits are dry and indehiscent, they may be called seeds. Such fruits are the caryopsis or grain, the achene, characteristic of Compositae, the schizocarp, illustrated by Umbelliferae, and the nut.

Food stored in seeds is a source of energy for the germination and early development of the seedling, but it is also of the utmost importance for the nutrition of man and other animals. Seeds are rich sources of carbohydrates, fats, and proteins, as well as of mineral matter and other accessory foods. Also many valuable ingredients of medicines are found in some seeds.

Dispersal of Seeds.—Many seeds have become adapted to dispersal by various agents, including wind, water, birds, fur-bearing animals, and man.

The wind is one of the principal agents concerned. A large number of plants rely entirely upon the small size of the seed and its light weight for distribution. Among these are orchids, poppies, and gentians which produce capsules opening in various ways to expose the minute seeds within them to the wind. Other seeds or fruits have developed special structures to facilitate dispersal by wind. Winged seeds are characteristic of lily, tulip, and pine, for example, and maple and elm are among those plants with winged fruits. Many grasses also have wings on specialized coverings of the seeds. The so-called parachute seed pod of *Aristolochia,* a native of the Philippines, represents an extreme adaptation for dispersal by wind. When its seeds are ripe, the pods split to form six parts suspended by a thread attached to the stem of the vine. The split pod hangs upside down on the vine and the seeds are shaken out by the wind. Many members of the Compositae, such as the dandelion, have seeds with a tuft of fine hairs that facilitate wind dispersal.

Water may play an important part in the transportation of seeds for long distances. The distribution of the coconut palm over the surface of the earth, for example, is thought to be due in part to the germination of ocean-borne nuts which drifted or were carried by the current from their original location. Mature seeds of aquatic plants such as water lilies are covered with a gelatinous substance which gives buoyancy for their flotation away from the parent plant.

Birds are especially important in the dispersal of seeds associated with juicy pulp, such as berries and cherry. Seeds carried by fur-bearing animals are principally those of grasses or of weeds equipped with spines, such as cocklebur, tick trefoils, and sand burs. Human beings also carry such seeds on their socks, or other parts of their clothing. Ants have been observed to disseminate the seeds of *Trillium* and bloodroot.

Many plant families do not depend on any special agent but have developed mechanical devices for ejection of their seeds. Pressures and tensions are developed in the mature fruits throwing the seeds out. In the legume family, pods may twist into spirals, while touch-me-not pods simply collapse. In violets, the pods split into three valves which press on the enclosed seeds to release them. In the wood sorrels, the outer seed coats turn inside out with enough pressure to cast the enclosed seeds for some distance. In witch hazel, the inner, woody layer of the mature, drying seed capsule curves inward, producing pressure enough to shoot the seeds out with some force.

Seed dispersal is of prime importance for the survival and distribution of plants over the surface of the earth.

Germination.—Seedsmen, nurserymen, and home gardeners have all experienced difficulty at one time or another in the germination of seeds. If the seeds possess a dormant embryo, or impermeable seed coats, as is the case of many trees and shrubs, there are very definite and simple procedures which may be used to bring about germination (see section on *Dormancy*). If, on the other hand, the embryos are not dormant, but the seeds still fail to germinate under ordinary conditions, some other treatment must be given. Some of our common seeds have special germination requirements.

Certain specific temperature conditions are necessary for the germination of many forms. For example, wild columbine seeds germinate very poorly at a constant temperature as high as 25°C. but give excellent germination if the daily temperature alternates between 15° and 25°C. Annual delphinium or larkspur seeds show very poor seedling production at temperatures about 15°C. but can be induced to germinate at temperatures as high as 30°C. by pretreatment on a moist medium for one, two, or three weeks at temperatures of about 10° or 15°C. Lettuce seeds can also be made to germinate at high temperatures normally inhibitive by pretreatment for four days in a moist condition at 5°C.

The difficulties encountered by many rock-garden enthusiasts in the germination of seeds may be attributed to any one of several factors. Seeds of *Primula obconica* and *Ramondia pyrenaica* require light for germination. Although light is not essential for the germination of seeds of *Draba aizoides, Gentiana lagodechiana, Mimulus langsdorfii,* and *Primula denticulata,* exposure of all these seeds to light during the germination process permits seedling production at temperatures ordinarily inhibitive. Other rock-garden plants, such as *Calochortus macrocarpus, Camassia leichtlinii,* and *Lewisia rediviva,* germinate only at low temperatures of approximately 5°C. Still another group of rock-garden plants, including *Draba alpina, Meconopsis cambrica,* and *Gentiana crinita,* possess dormant embryos and must be pretreated at low temperature, after which germination proceeds at ordinary greenhouse temperatures.

Many weed seeds not only show a delay in germination but are capable of distributing their seedling production over a period of years. This fact is demonstrated repeatedly by the years of cultivation necessary to get rid of weeds in a garden plot, even if care is taken to eradicate all weeds as they appear and to prevent the introduction of new weed seeds. The soil contains many dormant seeds which produce plants promptly when cultivation, excavation, or erosion give them the moisture, temperature, and oxygen supply or the exposure to light required for germination.

Dormancy.—Seed dormancy is a term used to signify the failure of viable seeds to germinate when they are placed under conditions of moisture and temperature which would ordinarily

bring about sprouting. This is in contrast to the so-called dormancy of the dry, resting seed. The term, *afterripening,* signifies the preparation of the seed for resumption of growth. Dormancy is of definite advantage to the continuance of the species in that germination under conditions unfavorable for seedling survival is prevented. This is true for many temperate-zone forms whose seeds mature in the autumn. If germination took place immediately, the young seedlings would not be able to withstand the rigorous winter weather and would all be killed. Again, in the case of certain desert annuals, dormancy at maturity prevents germination at the close of a rainy growing season and the beginning of a dry season which the young seedlings could not survive. Some seeds possess impermeable seed coats which prevent their germination for years or even for centuries. This feature characterizes many of the legumes, as well as some other forms, and permits their distribution in time instead of space. In addition to the numerous seeds which are dormant in the dry state, there are many which have a prolonged primary dormancy or an induced secondary dormancy in the wet state. The most common example of the latter are weed seeds of various kinds which remain ungerminated and fully viable for years in the soil. Experiment has shown that some seeds fully imbibed with water live for as long as 60 years buried in the soil. This has also been demonstrated in many cases where unusual plants have appeared on excavated or bombed sites.

A type of dormancy of low intensity is that exhibited by many seeds at maturity but which disappears after a period of dry storage. This is characteristic of many grains and flower seeds and of some vegetable seeds, notably lettuce.

It has long been known that certain seeds, especially of the family Leguminosae, possess coats which prevent the absorption of the water necessary for germination. Among the known methods for making the coats permeable are shaking or mechanical scarification, soaking in concentrated sulphuric acid or alcohol, and hot water or other special temperature treatments.

Many plants, especially those of the temperate zone, have seeds with dormant embryos. The method commonly used to break this dormancy is pretreatment in a moist medium at low temperature, usually between 1° and 10°C. This process has been used by nurserymen for a long time under the term *stratification,* so called because of the practice of alternating layers of sand with layers of seeds for winter treatment. Some seeds with dormant embryos do not afterripen in a moist medium at low temperatures because their coats are impermeable to water, which must be absorbed before the necessary changes can take place. In these cases, it is essential to make the coat permeable by mechanical or chemical treatment after which a period at low temperature brings about the breaking of the dormancy.

The seeds described above which respond favorably to low temperature pretreatment become afterripened while still enclosed in the seed coats, and once growth has been resumed by the embryo, the green plant appears above ground in a short time. Another type of dormancy has been found in which the seed germinates to form a root without any pretreatment, but once the root is formed, low temperature must be given to break the dormancy of the shoot or the bud that forms it. This has been designated as epicotyl dormancy. The two-year lilies, the tree peony, and several species of Viburnum belong in this category.

When all of the coats of seeds of some rosaceous forms, such as peach, apple, and hawthorn, are removed, a certain percentage of the embryos, which require cold stratification for normal development, will grow at greenhouse temperatures to form dwarf plants. In such physiological dwarfs, normal growth is readily initiated after exposure of the seedling to a cold period.

Finally, an extreme type of dormancy is shown by seeds of such forms as Convallaria, Smilacina, and Trillium. These require pretreatment at low temperature to break the dormancy of the root, a period at high temperature to permit the root to grow, another period at low temperature to break epicotyl dormancy, and a second period at high temperature to permit the growth of the afterripened epicotyl to form a green shoot.

The cause or causes of physiological dormancy are not known, though many of the chemical and physical changes which accompany the breaking of dormancy are known. See also PLANTS AND PLANT SCIENCE—*Physiology and Biochemistry* (Dormancy).

Storage.—Seed storage methods are very important in the maintenance of viability of all seed types. The performance of any seed depends less upon its actual age than upon the conditions under which it has been stored. Experimental investigations of the effect of different factors on the keeping quality of seeds have demonstrated that temperature and moisture are of vital importance. It has been known for a long time that low temperature is more desirable than higher temperature, but temperatures above freezing, especially between 5°C. and freezing, have been considered adequate. The truth is, however, that a very moist atmosphere at 5°C. often brings about more rapid deterioration than ordinary room temperature. This emphasizes the fact that a cool place is not always the best place to store seeds. More recently, experimental evidence has shown the superiority of below-freezing temperatures to those just above freezing for maintaining seed viability. This difference becomes significant as the storage period lengthens to more than 10 years.

Seeds with high moisture content deteriorate more rapidly than those with low moisture, provided they will tolerate drying. Sealed containers are beneficial to maintain low moisture content. There is more rapid degeneration of seeds stored in sealed containers which are opened and sealed repeatedly than of seeds in sealed containers which are never opened from the time of storage to the time of testing. Under adverse temperature and humidity conditions, there may be a favorable effect of reduced oxygen supply.

Some seeds are short lived by virtue of the fact that they do not tolerate drying. Among these are citrus seeds and those of many tropical plants. Even these may have the life span extended by adjustment of moisture content and storage at a temperature of about 5°C.

The oldest known viable seeds are those of the Indian lotus found in a naturally drained lake bed in Manchuria. Radioactive carbon tests have shown their age to be 1040 ± 210 years.

cultural and vegetable seeds, to determine, as nearly as possible, the actual planting value of the seed lot and to be sure of the purity of the seeds, have come to be general practice. Seed laws in many parts of the world specify certain standards that must be met before seeds can be offered for sale. This has resulted in the development of special sampling and testing equipment and prescribed, detailed methods for testing the germination and purity of all types of commercial seeds. An important part of this testing deals with an examination of the seed sample for noxious-weed content and for other impurities, as well as the origin of the seeds, and testing for trueness of variety. More recently, emphasis is being placed on pathological considerations in seed testing, and procedures are being developed to test the seeds as hosts and carriers of disease organisms. Progress has been made in the standardization of national and international rules for seed testing in the interest of uniformity and of world trade. The responsibility for seed quality is placed upon the individual or firm which grows and markets the seed, but state and federal governments provide the control through special laboratories for seed testing.

In order to get a true index of the planting quality of seeds, their germination capacity must be tested under special conditions required by that seed. In most cases, the tests are very simple since the seeds germinate easily. However, light is required for germination of many grasses and some vegetable seeds, and potassium nitrate may be substituted for light requirement in some cases. Prechilling moist seeds at low temperature, high temperature treatment, combinations of low and high temperatures in daily alternations, mechanical abrasion of the seed coat, soaking in water, or predrying are some of the special procedures used to test these seeds.

In addition to the microscopic examination of seeds for purity and identification, sometimes other methods have to be used to determine variety. For example, Italian ryegrass can be distinguished from perennial ryegrass by a fluorescence test of the roots under ultraviolet light. Italian ryegrass roots fluoresce, while the others do not.

SEED INDUSTRY

The seed industry comprises the development, production, collection, cleaning, packaging, marketing, and shipping of seeds, which are a vital part of the economy of the world. Special services of geneticists and plant breeders who work to develop superior seeds; of physiologists who investigate the nutrition and other growth characteristics of the plant as affecting seed set and quality; of plant pathologists who are constantly working on disease problems; of growers who must learn the highly specialized techniques of seed production; and of equipment manufacturers who must supply the many types of apparatus and materials necessary for the different phases of the industry are required for the functioning of this very complex and highly important industry. A few figures will serve to emphasize the scope of the seed industry in the United States. The 1949 production of corn, for example, was 3,238,618,000 bushels valued at $4,034,035,000. In the same year 1,098,415,000 bushels of wheat and 1,864,780,000 pounds of peanuts, valued at $2,061,897,000 and $193,496,000 respectively were produced. Turning to forage crops, 104,950,000 pounds of clean seeds of alfalfa valued at $39,243,000 and 148,690,000 pounds of red clover seed valued at $45,306,000 were produced in 1950. In 1951, 100 commercial seed growers planted 83,953 acres of wrinkled garden peas, one of two principal types of peas grown, which yielded 94,699,000 pounds of seeds.

Hybrid corn may be taken as an example of one of the greater crop developments of all times. Geneticists have greatly improved a plant which has been in use for thousands of years by the establishment of pure lines and the subsequent hybridization of these lines to produce seeds which possess hybrid vigor manifested in the plants grown from them. The parent plants are grown side by side in large, isolated fields and are pollinated by wind. Only pollen from the male parent must be allowed to fall on the silks of the female parent, and this necessitates the removal of all of the tassels from the seed parent, involving much labor and expense. Furthermore, the accidental removal of leaves in the detasseling operation reduces the seed-producing capacity of the plant. Recent research has shown that cytoplasmic male sterility may be induced in the seed parents, thus eliminating the necessity of detasseling, since no pollen is produced on these male-sterile lines. In view of the fact that some 8 million bushels of seeds are needed to plant the corn acreage each year, the practical value of this research is great. It should also be pointed out that a double cross is used in corn hybrid seed production; the first cross being between two inbred lines and the second hybridization involving the crosses of these inbreds. This process must be repeated each year.

The superiority of hybrid seed corn is best demonstrated by the rapid rise in its use from a small beginning in 1933. Now, more than 75 per cent, and in some areas 100 per cent, of the corn acreage in the United States is planted with hybrid seed. The production and sale of hybrid corn seed had an estimated value of about $75 million in the United States in 1946. Since that time, it has been introduced in many other countries, including India, Germany, Italy, and France, where it is hoped that it will result in increased yield and solve some of the food problems for both livestock and people. Researchers are still scouting regions of Central and South America for promising corn varieties which have never been studied to date. They hope to develop still better strains of corn—bigger plants with larger ears, and with more resistance to heat, drought, excessive rain, cold, insects, and diseases.

In addition to the seeds grown for feed, for man, or for livestock, there is a large and thriving flower seed industry. The importance of tree seeds, also, should not be overlooked. They are required for reforestation of lands denuded by erosion, burning, or cutting and are essential in conservation and timber production and the maintenance of a food supply for wildlife. In 1939, about 484,000 acres of land were replanted in this program, requiring about 145 tons of forest seed. It is estimated that 45 million acres are still in need of planting in the United States.

In time of war the seed industry is one of utmost importance. For example, approximately a billion packets of vegetable seeds as well as grass and clover seeds totaling 42 million pounds were purchased for lend-lease in 1941 and 1942.

The beginnings of the seed trade in the United States are obscure. The early colonists brought seed with them, and these were added to the

seeds of the Indians of precolonial times. Seeds were saved by the growers for their own use and doubtless other seeds were imported. Some of the earliest advertisements offering seeds for sale appeared in Boston and Philadelphia papers about 1720. The inadequate mail service during the 18th century permitted only local distribution, but with the establishment of a system of post riders, seedsmen began to operate on a larger scale. The American Seed Trade Association was founded at New York City, N. Y., on June 12, 1883. This organization has been effective in promoting the treatment of seeds for disease control and the certification of seeds for both freedom from disease and trueness of variety. See also section —*Seed Testing and Analyses.*

LELA V. BARTON,
Boyce Thompson Institute for Plant Research, Inc.

SEEGER, sē'gĕr, **Alan,** American poet and soldier: b. New York, New York, June 22, 1888; d. Belloy-en-Santerre, France, July 4, 1916. Following his graduation from Harvard in 1910 he did desultory writing, both in prose and verse. Although he rebelled against many literary conventions, he did employ the ordinary verse forms. In 1912 he went to Paris, where he continued his writing and attended classes in painting. At the outbreak of World War I he at once enlisted in the French Foreign Legion as a private. Despite his fatalistic philosophy he was a good soldier and won the Croix de Guerre and Médaille Militaire. He wrote many poems, the most famous of which is *I Have a Rendezvous with Death.* His *Collected Poems* were published in 1916.

SEEKONK, river, Rhode Island. See BLACKSTONE.

SEELEY, sē'lĭ, SIR **John Robert,** English historian and essayist: b. London, England, Sept. 10, 1834; d. Cambridge, Jan. 13, 1895. He was graduated from Christ's College, Cambridge, in 1857, and subsequently was elected a fellow and made classical lecturer there. He published under the pseudonym of John Robertson a book of poems in 1859, and was appointed in 1863 professor of Latin at University College, London, where he continued until 1869. His controversial essay, *Ecce Homo,* published in 1865, is in many respects the best and certainly the best known of his works. It was a simple account of the life and teaching of Christ, dealing with these wholly from the human side. He was professor of modern history at Cambridge in 1869–1895. Further publications of his are *Natural Religion* (1882), which endeavors to establish a reasonable religion and avoids a discussion of supernaturalism; *The Expansion of England* (1883), a popular narrative from the imperial viewpoint; *The Growth of British Policy,* 2 vols. (1895); and *The Life and Times of Stein* (1878).

SEELY, John Edward Bernard (1ST BARON MOTTISTONE), British political leader: b. May 3, 1868; d. London, England, Nov. 7, 1947. Educated at Harrow and Trinity College, Cambridge, he entered the Inner Temple in 1897. He participated both in the South African War and World War I, was undersecretary for the colonies, 1908–1910, undersecretary of state for war, 1911, and the following year began a two-year term as secretary of state for war. He served numerous terms as a member of Parliament and in 1918 reached the military rank of major general. The French government awarded him a gold medal in 1891 for saving life at sea, and in 1933 he was created a baron.

SEELYE, Julius Hawley, American clergyman and educator: b. Bethel, Conn., Sept. 14, 1824; d. Amherst, Mass., May 12, 1895. He was graduated from Amherst in 1849 and afterward studied theology at the Auburn Theological Seminary and at the University of Halle. From 1853 to 1858 he was pastor of the First Reformed Dutch Church of Schenectady, N. Y., from which charge he was called as professor of philosophy to Amherst College. In 1876 he succeeded to the college presidency. He was a member of a commission for the revision of the tax laws of Massachusetts and from 1875 to 1877 was a member of Congress. His writings include *The Way, the Truth, and the Life* (1873), *Christian Missions* (1875), and *Empirical Psychology* (1882).

His brother, LAURENUS CLARK SEELYE (b. Bethel, Conn., Sept. 20, 1937; d. Northampton, Mass., Oct. 12, 1924), became president of Smith College in 1873. He had graduated from Union College in 1857 and during the next six years studied theology at Andover, Mass., and at Heidelberg and Berlin, Germany. After a brief pastorate in the Congregational Church at Springfield, Mass., he accepted the chair of English literature at Smith in 1865. In 1910 he became president emeritus.

SEFSTROM, sâv'strûm', **Nils Gabriel,** Swedish chemist: b. Ilsbo, Halsingland, Sweden, June 2, 1787; d. Stockholm, Sweden, Nov. 30, 1845. He received a doctor's degree in 1813. From 1812 to 1820 he taught chemistry at the royal war college in Karlberg. Thereafter, until 1838, he taught chemistry at the newly built mining school at Falun. He joined the royal mining college at Stockholm in 1839 as director of laboratories, of the mineral exhibits, and of the library. He was a member of the Swedish Royal Academy of Sciences beginning in 1815. In 1830 he rediscovered the element vanadium.

SEGANTINI, sā-gän-tē'nē, **Giovanni,** Italian artist: b. Arco, Trentino, Italy, June 15, 1858; d. Schafberg, Switzerland, near Saint-Moritz, Sept. 28, 1899. Bred in poverty, his mother dead, and abandoned by his father, he made a living for himself in his early teens by herding flocks in the hills during which time he amused himself by sketching surrounding scenes. His drawings becoming known, and after further vicissitudes, he studied at the Brera Academy, Milan, while supporting himself by portrait painting and tutoring in art. In 1882 he settled near Lake Como, where he painted the *Ave Maria,* which was awarded the gold medal at the Amsterdam Exhibition in 1883. He moved to the Swiss Alps in 1886, where under the influence of Frédéric Millet he sought his subjects in the lives of the lowly agriculturalists of the region. *The Drinking Place* won the gold medal in Paris in 1889 and *Ploughing in the Engadine* won the gold medal at Turin, 1892. Among others of his famous works are *At the Tether, Dark Hours, Unnatural Mothers,* and *Punishment of Luxury.* At Saint-Moritz is the Segantini Museum, where many of his pictures are exhibited, including his unfinished panorama of the *Alpine World.*

SEGESTA, sē-jĕs'tē, (Gr. *Egesta*), an ancient city of Sicily, toward the northwestern extremity of the island, eight miles southwest of the modern Alcamo. It was built upon the steep Mount Barbaro, near the river now known as Fiume Gaggera. Segesta formed an alliance with Athens in 416 B.C., and in 413 B.C. with the Carthaginians (after the fall of Syracuse). In the first Punic war, it became subject to Rome, thus acquiring the name Segesta. The ruins of the ancient city are extensive; the most remarkable are the Greek theatre and temple.

SEGMENTATION OF THE EGG. See EMBRYOLOGY.

SEGOU, sā-gōō', French West Africa, town of the French Sudan, situated on the right bank of the river Niger 350 miles southeast of Tombouctou. It is the center of an important agricultural region whose produce is transported by water to railhead at Koulikoro. An extensive system of irrigation has been carried out in the Segou district north of the Niger. Pop. (1940) 8,391.

SEGOVIA, sā-gō'vyä, or **WANKS,** river of Central America, for much of its course forming the disputed boundary between Honduras and Nicaragua. Rising in northwest Nicaragua, it flows northeast for a distance of some 450 miles, entering the Caribbean Sea at Cabo Gracias à Dios; it is navigable for 150 miles from the mouth, but the upper part of its course is obstructed by cataracts and shallows. The Segovia is also known as Cape River, or Coco.

SEGOVIA, Spain, (1) a central province, northwest of Madrid Province and southeast of the Province of Valladolid, 2,682 square miles in area. For the most part the province is an elevated tableland, terminated, in the southeast, by the lofty Sierra de Guadarrama. The principal agricultural products are wheat, barley, madder, flax, and hemp; grapes, olives, carobs, and chestnuts also do well; and large numbers of sheep are raised. Minerals found in the mountainous parts of the province include silver, copper, lead, and iron, and there are quarries of excellent granite and marble. Pop. (1944 est.) 194,752.

(2) Capital of the province of the same name, a walled town standing high above the river Eresma, 43 miles northwest of Madrid, dominated by an ancient citadel, or alcazar. Its old-fashioned buildings are quaint but stately; its cathedral, a fine specimen of the Gothic, is scarcely surpassed in Spain. There are, besides, several other churches, suppressed convents, a bishop's palace, a mint, a military academy, a church seminary, a theater, hospitals, and a picture gallery. The lofty aqueduct (built by Trajan) is the finest Roman ruin in Spain. Segovian Romanesque architecture is one of the most remarkable provinces of Spanish art. In few parts of the world can so much fine architecture and decorative sculpture be found. Paper, linen, and glass are manufactured. The kings of Castile and Leon made Segovia their place of residence. In 1808 the town was entered and sacked by the French troops. Pop. (1940) 24,258.

SEGREGATION, in geology that tendency of mineral ingredients to separate from the parent magma, and to crystallize out, each by itself. In granite and other crystalline massive rocks, veinlike portions are found in which the matter is either coarser or finer than the rest of the mass. These were produced at the final stage of cooling of the rock, when the segregation from the original molten or viscous mass occurred along certain lines or around particular centres. These are termed segregation veins. Cracks or cavities may also be filled with mineral matter segregated from the surrounding rock mass. See MINING.

SEGUIDILLA, sā-gē-dēl'yä, a Spanish form of versification, consisting of four generally assonant lines, of seven and five syllables alternately. It usually has a close of three verses, called *estribillo,* of which the first and last lines rhyme.

SEGUIN, sā'gwĭn, **Edouard Onesimus,** American psychiatrist: b. Clamecy, France, Jan. 20, 1812; d. New York City, Oct. 28, 1880. He was the father of Edward Constant Seguin (q.v.). In 1839, after studying medicine under Jean Gaspard Itard, he opened a school in Paris for the teaching of the feeble-minded. Immigrating to the United States in 1849, he established several similar institutions. He practiced in Ohio, first in Cleveland and then in Portsmouth, before settling in New York City. In 1861 he obtained a medical degree at New York University. He was commissioner of the United States to the Austrian international exposition, in Vienna, in 1873. During his later years he gave attention to the study of animal heat and invented a physiological thermometer.

SEGUIN, Edward Constant, American neurologist: b. Paris, France, 1843; d. New York, Feb. 19, 1898. He was the son of Edouard Onesimus Seguin (q.v.), and accompanied his father to the United States in 1849. Educated in the public schools of Ohio, he began studying medicine under his father in 1861, and continued it at the College of Physicians and Surgeons, Columbia University, where he graduated in 1864. He spent two years in the medical department of the Union Army while enrolled as a student, and contracted a tubercular difficulty, to cure which he served among the United States volunteers at Little Rock, Ark., during part of 1864–1865, and again in New Mexico during 1868–1869. During the winter of 1869–1870 he studied nervous diseases under leading specialists in Paris, and following his return to the United States he entered private practice in New York City. For 10 years he was pathologist to the Connecticut Hospital for the Insane; and from 1871 to 1885 he was a member of the faculty of Columbia's College of Physicians and Surgeons, lecturing on the spinal cord and on nervous diseases. In 1873 he founded a clinic for nervous diseases; he advocated the use of drugs when administered with care, and, in stubborn cases, the use of iodides in large doses. During 1876–1878 he edited *American Clinical Lectures,* and from 1879 to 1884 he was editor of the *Archives of Medicine;* in 1884 he published *Opera Minora.* He was one of the founders of the American Neurological Association and of the New York Neurological Society. He bequeathed to the Academy of

Medicine his large collection of books and pamphlets relating to nervous diseases, and to the College of Physicians and Surgeons other books and instruments.

SEGUIN, sū-gēn′, **city, Texas, county seat** of Guadalupe County, on the Guadalupe River, altitude 530 feet, 33 miles east-northeast of San Antonio, on the Southern Pacific Railroad. In a cotton raising and diversified farming region, its manufactures include brick and tile, clothing, insecticides, and dairy products. Settled in 1832 and platted in 1838, it was incorporated in 1853. It has a council-management government. Pop. (1950) 9,733.

SEGUR, Comte **Louis Philippe,** French dramatist and historian: b. Paris, France, Dec. 10, 1753; d. there, Aug. 27, 1830. He was forced by his father to enter military life, served under Rochambeau in America, was appointed ambassador to Russia in 1783, and after the overthrow of the monarchy devoted himself to literature. Appointed a member of the council of state by Napoleon, he became a member of the Chamber of Peers after the Restoration. He published *La politique de tous les cabinets de l'Europe* (1793); *Théâtre de l'Hermitage* (1798); *Tableau historique et politique de l'Europe de 1786–96* (1800); *Histoire des principaux événements du règne de Frédéric-Guillaume II* (1800); *Histoire universelle* (1817); *Histoire de France,* 2 vols. (1824–1834); *Mémoires ou Souvenirs et Anecdotes* (1825); *Oeuvres completes* 34 vols. (1824 et seq.).

SEGUR, Comte **Philippe Paul,** French historian, son of the preceding: b. Paris, Nov. 4, 1780; d. there, Feb. 25, 1873. He entered the army in 1796 and rose to be brigadier general and aide-de-camp to Napoleon during the Russian campaign. He was made a peer by Louis Philippe, and after the second Restoration retired to private life. He wrote *Histoire de Napoléon et de la grande armée en 1812* (1824); *Histoire de Russie* (1829); *Histoire de Charles VIII* (1835).

SEGURA, sā-gōō′rä, the Tader of the Romans, a river of southeastern Spain some 200 miles in length. Its head waters are three widely branching mountain streams, one descending La Sagra peak in Granada from an altitude of 7,875 feet, the others flowing down from the Sierra de Segura in Jaen. The river trends in an easterly direction past the city of Murcia to empty into the Mediterranean 19 miles southwest of Alicante. As it drains semiarid highlands and much of its volume is diverted to irrigate the fertile lower valley, even its estuary is navigable only to small boats.

SEHESTED, sē′ĕs-tāth, **Hannibal,** Danish statesman: b. Arensborg Castle, Ösel Island (then Danish), 1609; d. Paris, Sept. 23, 1666. Educated abroad, he returned to Denmark in 1632 and held posts at the court of Christian IV. Sent to Sweden to negotiate a treaty with Oxenstierna and propose a marriage between Crown Prince Frederick and Gustavus Adolphus' heiress, Christina, he was unsuccessful. Some years later he married his sovereign's daughter Christine and was appointed viceroy of Norway (1642). During Christian's second war with Sweden (1643–1645) he ably supported the Danish cause, invading Sweden four times. Thereafter, in order to strengthen the defense against Sweden he continued to improve Norway's finances and economy and build up her naval force. The machinations of his enemies in the Danish Rigsraad drove him into exile in 1651; but Frederick III recalled him in 1660. He negotiated the peace with Sweden and was rewarded with high offices.

SEIDEL, sī′d'l, **Emil,** American socialist politician: b. Ashland, Pa., Dec. 13, 1864; d. Milwaukee, Wis., June 24, 1947. He learned the wood carver's trade in Germany. One of the organizers of the Wood Carvers' Union and of the Socialist party at Milwaukee, Wis., he was Socialist candidate for governor of Wisconsin in 1902; and was elected mayor of Milwaukee in 1910, the first Socialist mayor of a major American city.

SEIDL, zī′d'l, **Anton,** Hungarian composer and musical director: b. Budapest, Hungary, May 6, 1850; d. New York, March 28, 1898. He studied at the Leipzig Conservatory, and later at Budapest under Hans Richter, and by that musician was recommended to Richard Wagner when the latter was preparing for the opening of the Baireuth Festspielhaus. As a consequence he came into intimate association with Wagner and acted as stage manager during the first season of music dramas there in 1876. In 1878 Seidl became musical stage manager at the Royal Opera House, Vienna, and the next year migrated to Leipzig where he was made conductor. After conducting the Nibelung dramas at London in 1882 he joined a company traveling through Germany, Austria, Hungary, Italy, Belgium and Holland during the seasons of 1883–84, which produced only the Wagner operas. He was made conductor at the Metropolitan Opera House, New York, in 1885 after the death of Dr. Leopold Damrosch, and lived in America thereafter.

SEIDLITZ POWDER, an aperient powder named from the mineral spring of Seidlitz or Sedlitz in Bohemia.

SEIGNIORIAL TENURE. The system of Seigniorial Tenure was that system of public and private relations based upon the tenure of land which the French government undertook, during the course of the 17th and 18th centuries, to introduce into its North American colonies, and more especially into the colony of New France, now Canada. The system of feudal—or as in its later stages it came to be called—seigniorial tenure, was deeply rooted in France, and it is easy to understand how its introduction into the colonies appealed to Richelieu as a means of providing estates for many of the landless aristocrats of France. Moreover as feudalism was now so far advanced in decay as to be no longer a menace to the central power, it is easy to see how the system appealed to the Bourbon monarchs as likely to permit in the colonies that centralization of authority which characterized France at this time.

As regards Canada, the seigniorial system had its origin in 1627 when the French King granted to the Company of New France, more commonly known as the Company of One Hundred Associates, the whole of the French possessions in North America as one immense fief with full power to sub-grant it in seigniories to settlers.

During the whole 35 years of its existence, however, this company devoted almost its entire attention to the development of the lucrative fur trade; very few settlers were sent out to the colony, with the result that while over 60 *in extenso* grants of seigniories were made, almost none at all were ever taken possession of by the grantees. But in 1663 the company was compelled to surrender its charter and extensive territorial rights, the Crown taking into its own hands the supervision of colonial affairs and providing New France with a royal government corresponding roughly to that established in the French provinces at home. From this time on settlers came in increasing numbers; power was given the colonial governor and intendant to make grants of seigniories subject to royal ratification, and during the last quarter of the 17th century these were made freely. In no case were grants made to absentees; each applicant for a seigniorial grant had to prove himself a bona-fide colonist. Large numbers of the settlers were sent over at the royal expense and once in the colony, every inducement was given them to remain. Even the detachments of French regular troops sent out to the colony were disbanded there and both officers and men were encouraged, by liberal grants both of land and money, to become permanent residents of New France.

As to the size of the seigniories granted, there was no fixed rule: they varied from small plots containing a few square *arpents* to huge tracts 10 by 12 leagues in area. Much depended on the position occupied by the settler before his immigration to the colony and upon the available means which he had for the development of his grant. But whatever the area of the grants, they almost invariably assumed the same shape,—that of a parallelogram with the shorter end fronting on the river. On receiving his grant the new seignior was under obligation to repair at once to the Château de Saint Louis in Quebec, there to render his fealty and homage to the governor as the representative of the Crown. Within the next 40 days he was required to file with the registrar-general his *aveu et dénombrement,* or statement showing clearly the location, extent, and nature of his seigniory. A similar statement containing full information regarding the development of the holding was required every time the seigniory changed owners. No payment was exacted from the seignior in return for the original grant, but an exaction known as the *quint* became payable on each mutation of ownership by sale, gift or inheritance other than in direct succession. This amounted to one-fifth of the estimated value of the seigniory, but of this amount it was the custom of the Crown to give a rebate of one-third. As the seigniories increased in value very slowly this burden was never an onerous one. In making the grants, the authorities usually reserved the right of taking, from the granted seigniories, such locations as might at any time be found necessary for the construction of fortifications or other public works, such oak and pine timber as might be found suitable for use in the royal shipyards, and the right to a share in all mines and mineral deposits found in the seigniory.

In France the seignior was under no obligation to sub-grant the lands within his seigniory, but by a series of royal edicts—more notably the Edict of Marly (1711)—this obligation was imposed upon the seigniors of New France in the interest of colonial development. From 1711 onwards it was incumbent on all seigniors in Canada to sub-grant portions of the unoccupied lands of their seigniories to any settlers who applied for such grants, on whatever terms were customary in the neighborhood without exacting any bonus or *prix d'entree.* If the seignior refused to do this, power was given the governor and intendant to step in and to make the grant, the seigniorial dues in such case to become payable to the Crown. Furthermore, from time to time various edicts revoked or curtailed the grants made to such seigniors as did not seem to be showing sufficient zeal in having their lands granted to settlers. In this way every seignior was compelled to become, after a fashion, the immigration agent of the coloniel authorities, and it was this particular feature which serves most prominently to differentiate the seigniorial system in Canada from its prototype at home.

Grants made by the seigniors to settlers were called grants *en censive.* These likewise varied considerably in size, but almost invariably assumed the same shape as the seigniory within which they lay. Over them the seignior retained a variety of rights, some financial, some judicial and some merely ceremonial or honorary in their nature. Among the former was the annual payments known as the *cens et rentes,* the former payable in money, the latter usually in produce. The *cens* was a very small due, amounting usually to a few *sous* per superficial *arpent* and valuable to the seignior mainly as establishing his claim to other and more important rights. The *rentes* was payable annually in grain, cattle or poultry but might be commuted by agreement of the parties into a fixed money payment. Then there was the *lods et ventes,* a mutation fine payable at every change of ownership. This amounted to one-twelfth of the mutation price, and of it the seignior usually remitted one-fourth, although he was under no legal obligation so to do. To guard himself against loss of his proper *lods et ventes* through sales of *en censive* holdings at less than their actual value, the seignior possessed the *droit de retraite* by virtue of which right he might preempt any holding thus sold by payment to the purchaser of the mutation price, within 40 days from the date of the sale. Then there was the *droit de banalité* or the exclusive right of the seignior to erect a grist mill within the limits of his seigniory and to compel his *censitaires* to have their grain ground there and not elsewhere on pain of confiscation. The amount of toll receivable for this service was fixed by a royal edict at one-fourteenth of the grain ground. During the greater part of the French régime this incident bore more heavily upon the seignior than upon his *censitaires,* for except in the more populous seigniories, the amount of toll received rarely sufficed to pay expenses. At the same time the colonial authorities compelled the seigniors to provide mills in their seigniories on pain of losing the right for all future time. Finally, there was the much-detested *corvée,* or right of the seigniors to exact from their *censitaires* a certain quota of labor on the seigniorial lands without compensation. The amount allowable varied in different seigniories but as a rule the *censitaires* were permitted to commute it into a fixed money payment. An ordinance of the superior council in 1716 forbade the exaction of *corvée* during seed time and harvest. In addition to the foregoing main rights the seignior ordinarily reserved for

himself the privilege of taking from the lands of the *censitaires* such wood and stone as might be found necessary in the erection of the seigniorial manor house, mill or church, and in some cases the right of taking wood for fuel. In many cases he likewise reserved the right of claiming a share in all the fish caught by his *censitaires* in the waters of the seigniory.

Most of the seigniors possessed certain judicial rights. These, however, were not inherent in the ownership of a seigniory, but were specifically granted by the Crown. This grant might convey merely the right of *basse justice* in which case the seignior was empowered to deal with minor causes in which the amount in dispute did not exceed a few *sols*. The grant of *moyenne justice* gave him a large jurisdiction, while the grant of *haute justice* gave full judicial power in all cases except those such as treason and counterfeiting in which the Crown was directly concerned. As a rule all three degrees of judicial power were conferred on the seignior. But in every case an appeal lay to the royal courts of the colony. As the exercise of his judicial powers brought the seignior very little profit the seigniorial courts never became a very important element in the colonial judicial system.

The remaining rights of the seignior were merely honorary and afforded him no financial return. He was entitled to the fealty and homage of his *censitaires,* to a front pew in the parish church, to certain precedence at the sacraments, to the erection of a Maypole at his door each May Day and, in general, to the respect and deference of his dependents. A number of seigniors who showed zeal in the development of their holdings received patents of nobility but it must be borne in mind that the possession of a seigniory in New France did not of itself give noble rank. Herein Canadian feudalism again differed from its prototype in France. The French seignior was always a noble; the Canadian very rarely.

At the close of the French régime nearly 8,000,000 *arpents* of land had been granted out to be holden under the seigniorial tenure. The system had become so deeply rooted in the colony that the English authorities, after the conquest, did not venture to take the drastic step of supplanting it in favor of the English system of tenure in free and common socage. The old system was allowed, therefore, to remain intact, but as the colony became more thickly settled many of the seigniorial exactions became burdensome. The *droit de banalité* became especially so. Moreover, the new English courts failed utterly to afford the *censitaires* that protection against the seigniors which the authorities of the old régime had given. From time to time the legislature of Lower Canada sought to deal with the growing complaint that the operation of the system was retarding the development of the province but found it extremely difficult to devise any plan which would be satisfactory to the tenants and at the same time protect the vested interests of the seigniors. In 1825 an act was passed giving to the parties concerned the right to commute all seigniorial dues into a lump sum by mutual agreement but very few took advantage of the legal permission thus accorded. It was not until 1854 that by the Seigniorial Tenures Abolition Act a general scheme for the compulsory commutation of all seigniorial obligations received the assent of the Canadian legislature. This act provided for the establishment of a special court to determine just what seigniorial claims were justifiable and on a basis of its decisions each seignior was awarded a certain indemnity for the loss of his rights. Part of the amount was paid him from the public treasury; the balance became an annual rent charge on the lands of the tenants, which annual charge, again, might be commuted into a lump sum if the tenant so desired.

As a matter of fact relatively few of these *rentes constituées* were commuted, and for nearly a century they continued to be paid, although with more or less grumbling. Various schemes for extinguishing the annual rents by means of aid from the public treasury were broached from time to time, but not until a series of enactments culminating in the Seigniorial Rent Abolition Act passed by the provincial legislature in 1941 (S.R. Québec, 1941, Chapitre 322) was this problem solved. The arrangements made by this statute are somewhat complex, but in general they provided for the organization and incorporation of "syndicates" with power to borrow on the credit of the Province and to use such funds for the commutation of the constituted rents by payments capitalized at six per cent. Repayments to the syndicates out of local taxes are spread over a term of years.

Emeritus Professor of History and Government, California Institute of Technology.

SEIGNORY, or **SEIGNIORY**, (1) in English law, the lordship retained by a grantor after alienation of land in fee simple, and regarded as an incorporeal hereditament. The seignory dates back to Roman times, and later found its way to England, where the only seignories now existing are those created before 1290. By a statute passed in England in 1882, a tenant for life of a manor may alienate the seignory of any freehold land within such manor. The lordships of manors are the only seignories of consequence today in England.

(2) In Canada, land held by a tenure resembling that of feudal times; also, a seignor's mansion. See Seigniorial Tenure.

SEINE, sān, the Sequana of the Romans, an important river of France. It rises in the Plateau of Langres, 1,545 feet above the sea, some 18 miles northwest of Dijon. From this site, marked with the statue of a water nymph, it flows in a northwesterly direction to the English Channel, some 250 miles distant, although its winding course has a length of 482. Shorter than the Loire or the Rhone, and inferior in volume, the Seine maintains a steadier flow with an average discharge of more than 10,000 cubic feet a second. Disastrous floods have sometimes occurred, however, for in January 1910 water

levels rose 24 feet in Paris. The Seine has many branches. From the south the most important is the Yonne; from the north the Marne, 30 miles longer than the upper Seine, and the Oise. Below Paris the river winds through a pleasant countryside by a series of broad loops and empties into the sea by a long estuary impeded by extensive sand bars. Several important French cities owe their existence to the Seine; the port of Havre at the mouth, historic Rouen with its fine cathedral, and Paris, the heart of the country. Here an island in the channel marked the first settlement, and here the river is crossed by many artistic bridges. The Seine and its tributaries provide a maze of busy waterways. Ships of 20-foot draught ascend to Rouen, and smaller vessels to Paris. Curious phenomena of the lower river are the tidal bores, several feet high, which sweep inward from the sea, and here the banks are protected by dykes. Canals, designed for barges, give access to the Loire, the Rhone, the Rhine, the Meuse, and the Scheldt. The valley is of great historic interest and several tributaries, notably the Marne and the Aisne, were marked by bloody conflicts during World War I.

SEIPEL, zī'pĕl, **Ignaz,** Austrian statesman and Catholic priest: b. Vienna 1876; d. Aug. 2, 1932. Educated at Vienna University, he held professorships at Salzburg 1909–1912 and Vienna 1917–1918; became minister of public works 1918 and leader of the Christian Socialists in the Assembly, 1919. In 1922 he succeeded Johann Schober as state chancellor, but resigned in 1924 owing to strong opposition. On June 1, 1924 he was shot and seriously wounded by a young Socialist. In October 1926 he again became Chancellor and, in addition, foreign minister. He did great work in restoring the shattered finances of the country and introducing internal reforms. Author of *The Economic Teaching of the Fathers* (1909); *State and Nation* (1916).

SEISIN, *in law,* (1) possession of land by one claiming a freehold therein; also, the land so possessed. The possession must be actual and by a person entitled to the land or by one claiming a freehold interest therein. If the person having possession is disseized by one who intends to hold the freehold, either with or without legal right, the freehold is thereby transferred to the disseizor. Actual possession is known as "seisin in deed," while a right of present possession is known as "seisin in law."

(2) The ceremony accompanying the delivery of possession of land held in freehold: in this sense often called "livery of seisin."

SEISMOGRAPH, sīs'mō-grăf, or **SEISMOMETER,** an instrument for recording the period, extent and direction of each of the vibrations which constitute an earthquake. For a complete seismograph, three distinct sets of apparatus are required: (1) To record horizontal motion; (2) to record vertical motion; and (3) to record time. The horizontal and vertical motions must be written on the same receiver, and if possible side by side, while at the instant at which the time is recorded a mark must be made on the diagram which is being drawn by the seismograph. The first instruments were merely modifications of the seismoscope (q.v.), but successive improvements have been introduced, and the seismograph has been brought to a high pitch of perfection. Some of the best, if not the best, forms known are in use in the Imperial Observatory at Tokio, Japan. Milne's pendulum seismograph is a common form. This has a horizontal pendulum, swinging like the boom of a schooner. At the movable end of the pendulum is a box with a light which shines through the hollow pendulum rod, coming out through slits. By an ingenious mechanism any trembling of the light coming through the slits is recorded on a band of paper passing over a slowly moving timed cylinder. The Marvin seismograph, used by the Weather Bureau at Washington, employs a pendulum pointing upward, as in a metronome. The balance mechanism is of exceeding delicacy, and the mounting of the instrument is extremely solid to protect it from local vibrations. The record is taken on a traveling paper band in the ordinary manner.

SEISMOLOGY, sīs-mŏl'ō-jĭ, that branch of physical science which is concerned with the study and investigation of the phenomena of earthquakes, their causes and effects, their distribution, and the various circumstances attending their occurrence. Its pursuit is regarded as of the utmost importance to geological and other forms of terrestrial research. Seismology, however, is not limited to the study of earthquakes in the usual restricted sense, but deals with related phenomena occurring under many and differing aspects. According to leading authorities, it should investigate minute movements or tremors of the earth which escape ordinary observation; pulsations of the earth which, by reason of the length of their period, are not noticed; and oscillations, or elevations and subsidences of the earth which slowly alter the relative land and sea levels. Seismology has been developed almost wholly since the beginning of the 19th century, and must still be regarded as in the early stages of its progress; but already it has a great and growing body of materials and of literature, and its possibilities seem to point to the application of the science in practical ways. One of these, it is confidently predicted, will be the warning of dwellers in seismic regions when earthquakes impend. See also EARTHQUAKE.

SEISMOSCOPE, the earliest and simplest form of earthquake recorder. The first known was invented by a Chinese named Choko, in 136 A.D., and shows the occurrence and direction of an earthquake by the fall of a column, a principle which was afterward independently adopted in the West. Vessels filled with viscid liquids have been used; the height to which the liquid is washed up the side of the vessel being taken to indicate the intensity, and a line joining the points of maximum motion to denote the direction of an earthquake. Palmieri's seismoscope consists of horizontal tubes turned up at the end, partly filled with mercury. To intensify the motion of the mercury, small floats of iron are placed on the surface, attached by threads to a pulley provided with indices moving in front of a scale of degrees, whence the intensity may be read off. The direction is determined by the azimuth of the tube giving the maximum indication, several tubes being placed in different azimuths. Pendulum seismoscopes,

both swinging and fixed, have also been employed. See SEISMOGRAPH.

SEISTAN, sās-tän, or **HAMUN, Lake,** Afghanistan, a large, irregularly-shaped, shallow lake or swamp on the western frontier adjoining the Persian province of Khorassan; a division of this province is named Seistan after it. The lake is not a single expanse of water, but is divided into three depressions. A great part of the area is generally dry; but, as the basin has no outlet, when the Helmund and its other feeders are in flood this lake regularly overflows its boundaries, fertilizing large tracts of country. The great variations in the size of this remarkable salt water lake give it a peculiar interest. The rainfall of the region is usually not over three inches, and in the spring a few pools only mark the seistan area. But as the depression here is 1,000 feet below sea level, it attracts the drainage of some 125,000 square miles, so that at times the lakes or chain of lakes is quite extensive. A sufficiency of grain is easily grown to support the population — over 200,000. There is an abundance of water-fowl, living in the vast reed-beds of the salt marsh.

SEITZ, sīts, **Don Carlos,** American newspaper manager: b. Portage, Ohio, 24 Oct. 1862. He was graduated at Liberal Institute, Norway, Me., in 1880. He was city editor of the Brooklyn *Eagle* in 1889–91; was later connected with the New York *Recorder* and with the Brooklyn *World;* advertising manager 1895–97, business manager 1898–1923, New York *World;* manager *Evening World,* 1923–26; associate editor *Outlook,* 1926–27; associate editor *Churchman* from 1929. Among his writings are 'Surface Japan'; 'Whistler Stories'; 'Joseph Pulitzer'; 'Uncommon Americans'; 'The James Gordon Bennetts.' He died 4 Dec. 1935.

SEIXAS, sĕk'sąs, **Gershom Mendes,** American patriot and minister: b. New York, 14 Jan. 1745; d. there, 2 July 1816. He was a son of a refugee from Lisbon (who settled in New York about 1730), and choosing the Jewish ministry as his profession in 1766 was placed in charge of the Spanish and Portuguese Synagogue of his native city. On the outbreak of the Revolution he espoused the American cause, closing the synagogue rather than continue it under British rule. While the majority of his people went to Philadelphia he settled in Stratford, Conn., until in 1780 he was asked to organize a synagogue in Philadelphia, the «Mikve Israel,» where he continued to display his patriotic zeal. Owing largely to his efforts on 23 Dec. 1783 a modification in the test clause in the Pennsylvania constitution was made, whereby Jews were subjected to no disqualification for office. After the evacuation of New York in 1784, the old synagogue was re-established and Seixas resumed his former charge. In 1787 he was appointed one of the trustees of Columbia College, holding the office uninterruptedly until 1815. When Washington was inaugurated in 1789 Seixas was selected as one of the ministers to take part in the ceremonies.

SEJANUS, sĕ-jā'nŭs, **Lucius Ælius,** son of a Roman knight, and favorite of Tiberius: b. Vulsinii in Etruria; d. Rome, 31 A.D. In 14 A.D. he was made commander of the Prætorian bands, and acquired the confidence of the suspicious Tiberius, to such an extent as to govern him completely; while the servile senate paid complete deference to the powerful favorite, the prætorian cohorts were also favorable to him, and there was no obstacle in the way of his attaining the supreme power he aimed at but Drusus, son of Tiberius, and the sons of Germanicus, Drusus and Nero, the nearest of kin to the emperor. Drusus was put out of the way by poison; the latter, with their mother, were banished and thrown into prison, a step which they did not long survive. Several friends of Germanicus were beheaded at the instigation of Sejanus; and when Tiberius finally retired from Rome, and withdrew from the government, Sejanus governed with absolute power, and the senate ordered that the statues erected in his honor should be publicly worshipped. But at the moment of his highest elevation the suspicions of Tiberius were awakened, and his measures were taken so cautiously, that Sejanus suspected nothing until openly accused by the emperor before the senate. He was then imprisoned, condemned to death, and executed on the same day. The historian Tacitus has given a searching and vivid, although possibly a prejudiced, account of the character and intrigues of Sejanus, while his fate is the subject of a tragedy of Ben Jonson's. Consult Tacitus, 'Annals' (iv, 1, 2, 3, 8, 39ff.; 74, and v, 6ff); Suetonius, 'Tiberius'; Jülg, 'Vita Lucii Ælii Sejani' (Innsbruck 1882); and Tarver, J. C., 'Tiberius the Tyrant' (New York 1902).

SEKAKUL, an African parsnip (q.v.).

SEKI KOWA, sā'kē kō'wą, or **SEKI SHINSUKE KOWA,** or **TAKAKAZU,** Japanese mathematician: b. Fujioka, near the present Tokio, province of Kōzuke, 1642; d. near there, 1708. He was of the samurai class and became the greatest mathematician of his time in Japan, benefiting, however, by the work of several great Japanese mathematicians immediately preceding him, among whom was Yoshida. He was famous both as a teacher and for his discoveries, and his work greatly improved the algebra of the Japanese, which had come to them from the Chinese. He understood the native calculus, *yenri,* which he may have invented; and also knew the principle of determinants. Most of his manuscripts are lost. Consult Mikami, Y., 'Development of Mathematics in China and Japan' (1913); and Smith, D. E., and Makimo, Y., 'A History of Japanese Mathematics' (1914).

SELACHII, sē-lā'kĭ-ī, the order of fishes now known more generally as the *Elasmobranchii,* which includes the sharks, rays and their allies. See ICHTHYOLOGY; SHARKS, ETC.

SELAGINELLA, sę-lăj-ĭ-nĕl'ą, club moss, a genus of mostly tropical plants with small scale-like leaves and propagated by spores. (See FERNS AND FERN-ALLIES). The species are very numerous, and widely distributed in warm regions. They are generally quadrangular, the two lower rows of small one-veined leaves larger than the upper two rows, thus giving a flattened look to the fronds. They are generally creeping plants, often forming moss-like mats of foliage, but in some species supported by other plants, are erect and often several yards long. Selaginellas are cultivated in green houses both as pot plants, for edgings, and for hiding bare earth,

with their verdant foliage, sometimes iridescent, or changing in hue. *S. lepidophylla,* a Mexican species, growing in flat rosettes, while not very beautiful, is one of the familiar resurrection plants, because it becomes desiccated in time of drought and revives when moist conditions return. When dried out, it rolls its branches inward forming a ball, in which condition it is blown to a new situation by the wind.

SELAH, sē'lȧ, a Hebrew word which occurs 71 times in the Book of Psalms and three times in the prayer of the prophet Habakkuk (Hab. 3), and is retained in the English authorized version of the sacred texts; in the Septuagint version it is represented by the word *diapsalma.* Its signification cannot be definitely ascertained, but commentators interpret it variously as indicating either a pause or repetition, or the end of a strophe, or playing with full power, or a short recurring symphony, or, finally, a bending of the body in reverence.

SELANGOR, sĕ-lăng'ẽr, one of the states of the Federation of Malaya, on the west coast of the Malay Peninsula. It is bounded on the north by Perak, on the east by Pahang and Negri Sembilan, and on the south and west by the Strait of Malacca. The area is 3,160 square miles, and the population numbers (1950 est.) 776,182. The coastline is some 100 miles in length, and the state extends inland a distance of almost 50 miles to the north-south mountain range of the Malay Peninsula. All the rivers are short; the principal ones are the Selangor, the Klang, and the Langat. Kuala Lumpur (pop., 1950, 225,000), the capital, lies 200 miles northwest of Singapore, on the main west coast railway line up the peninsula; the most important city in Malaya after Singapore, it is also the capital of the Federation of Malaya. From Kuala Lumpur a branch line of 27 miles runs to Port Swettenham, the state's seaport and chief port of the federation; on that line is Klang (pop., 1947, 33,506), an important rubber-planting center. Other towns include Kajang (pop. 6,000), 10 miles south of Kuala Lumpur, another rubber center; and Kuala Kubu (pop. 5,500), 25 miles north of the capital, whence a highway runs northeast into Pahang. Alluvial tin mining and rubber cultivation are the major industries of Selangor. Coal is also mined in the northeast end of the state, and coconuts, rice, and pineapples are cultivated on a considerable scale. Because of an attack upon Malacca, the Dutch drove the sultan of Selangor from his state in 1784, and eventually he was forced to acknowledge their suzerainty. With Dutch evacuation of Malaya, British influence became paramount, and in 1818 the sultan made a commercial treaty with the British governor of Penang. The state was placed under British protection in 1874, and it became one of the Federated Malay States in 1895. When the Federation of Malaya was formed in 1948 Selangor constituted one of its leading political units.

SELBORNE, sĕl'bôrn, **Roundell Palmer,** 1st earl of, English jurist and hymnologist: b. Mixbury, Oxfordshire, Nov. 27, 1812; d. Petersfield, Hampshire, May 4, 1895. After graduating at Christ Church, Oxford University, in 1834, he studied law and was called to the bar in 1837; in 1849 he became a queen's counsel. From 1847 until 1857 he was member of Parliament for Plymouth, and in 1861 he was elected to the House of Commons for Richmond, Yorkshire, thereupon becoming solicitor general in the Cabinet of Lord Palmerston and receiving a knighthood. As attorney general from 1863 to 1866 he was adviser to the British government on matters arising from the American Civil War. In 1872 he entered the Cabinet of William Ewart Gladstone as lord chancellor, being made Baron Selborne; his most important work in this office was to ensure passage of the Judicature Act through Parliament the following year. He lost this office with the fall of the Gladstone government in 1874, but resumed it when the Liberals again returned to power in 1880. In 1882 he received an earldom, but in 1885 he severed his connection with the Liberals because of differences with Gladstone on the issue of home rule for Ireland. A prominent Anglican churchman, he edited a hymnal entitled *The Book of Praise* (1863) and wrote works on church questions: *Notes of Some Passages in the Liturgical History of the Church of England* (1878); *Ancient Facts and Fictions Concerning Churches and Tithes* (1888).

SELBORNE, William Waldegrave Palmer, 2d Earl of, British statesman: b. 1859; d. London, Feb. 26, 1942. The eldest son of the 1st earl of Selborne, as Viscount Wolmer he was elected to the House of Commons in 1885. He supported the Conservative Party, and in 1895 he was appointed undersecretary for the colonies in the administration of the marquis of Salisbury. In 1900 he was given a seat in the Cabinet as first lord of the admiralty, and this office he gave up in 1905 to become high commissioner for South Africa and governor of the Transvaal and Orange River colonies. Serving in South Africa until 1910, he played a prominent part in facilitating the attainment of responsible government by the two new colonies and the establishment in 1910 of the self governing Union of South Africa. In 1915, during the early stages of World War I, he entered the coalition Cabinet as minister of agriculture, but the following year he resigned the office because of his opposition to the policy respecting Ireland of Prime Minister Herbert Henry Asquith. Like his father, to whose earldom he had succeeded in 1895, he was prominent in Anglican Church affairs.

SELBORNE, village, England, in the County of Hampshire, 52 miles south of London, known as the birthplace of Gilbert White (q.v.), author of the celebrated *Natural History and Antiquities of Selborne* (1789). The Selborne Society, for the preservation of plants and birds, was founded in Gilbert White's memory in 1885. White was buried in the churchyard at Selborne, of which he was curate; his house, "The Wakes," has been preserved.

SELBY, urban district England, in the county of West Riding, Yorkshire, on the Ouse 13 miles south of York. A Benedictine abbey was founded there in 1069 by a grant of William the Conqueror, and subsequently became of considerable importance. The abbey's Church of Saint Mary and Saint German, in several architectural styles, has been in part preserved. Selby is supposed to have been the birthplace of King Henry I. Pop. 10,064.

SELDEN, John, English jurist, antiquary,

Orientalist, and statesman: b. Salvington, Sussex, Dec. 15, 1584; d. London, Nov. 30, 1654. After studying at Oxford University he removed in 1602 to London and became a student of law at Clifford's Inn. In 1612 he was called to the bar at the Inner Temple. He formed friendships with some of the most learned men of the time, William Camden and Ben Jonson among the number, and he appears to have been one of the number frequenting the Mermaid Tavern, in Cheapside, home of the Mermaid Club, famous as the supposed meeting place of leading wits. His *Duello, or Single Combat* (1610) and some legal writings were followed by *Titles of Honour* (1614), a work of permanent value, and *Analecton Anglo-Britannicon* (1615)), a history of civil government in Britain before the Norman Conquest. With publication of *De Diis Syriis* (1617), a study of polytheism, he attained a European reputation as an outstanding Orientalist, and this was enhanced by treatises on rabbinical law. Great controversy arose among the English clergy with appearance of his *History of Tythes* (1618) which, while admitting their legal, denied their divine, right. The work was suppressed and Selden was brought before the Privy Council and made to renounce his views. He was believed instrumental in getting Parliament to deny in 1621 that it owed its rights and privileges to the crown, and for this he was imprisoned in the Tower of London. First elected a member of the House of Commons in 1623, and reelected in 1626 and 1628, he labored zealously for the advancement of civil and religious liberty. He supported the impeachment in 1626 of George Villiers, 1st duke of Buckingham, and two years later he helped draft the Petition of Right (q.v.) and spoke in support of it in the House of Commons. In 1629 he was once more sent to the Tower, on this occasion for his part in securing the resolution in the House against the levying of tonnage and poundage. Released a year later, he ceased political activity for a while and turned again to writing. He wrote *De Successionibus in Bona Defuncti Secundum Leges Hebraeorum* (1634) and *Mare Clausum* (1635); the latter, a reply to the *Mare Liberum* of Hugo Grotius, was dedicated, strangely enough, to King Charles I. These works were followed by *De Successione in Pontificatum Hebraeorum Libri Duo* (1638) and *De Jure Naturali et Gentium juxta Disciplinam Hebraeorum* (1640). In 1640 he was elected to the famous Long Parliament (q.v.) as one of the members for Oxford University, and there, the next year, he assisted in drafting the articles of impeachment of Archbishop William Laud. He took part as a lay member in the Westminster Assembly of divines, endeavoring to moderate the fanaticism, and shortly thereafter he was appointed keeper of the rolls and records of the Tower of London. Other writings at this period of his life included *Privileges of the Baronage of England* (1642), *Dissertatio de Anno Civili et Calendario Reipublicae Judaicae* (1644), and *Uxor Ebraica* (1646). He is best remembered, however, for his *Table Talk* (1689), reports of his utterances over 20 years compiled by his amanuensis, Richard Milward.

SELDES, sĕl'dĕs, **George,** American journalist and writer: b. Alliance, N. J., Nov. 16, 1890. He attended East Liberty Academy, Pittsburgh, Pa., and, during 1912–1913, Harvard University. After experience as reporter for the Pittsburgh *Leader* (1909–1910), night editor of the Pittsburgh *Post* (1910–1916), and managing editor of *Pulitzer's Weekly* (1916), he was a war correspondent with the American forces in France during World War I. In 1920 he was made head of the Berlin bureau of the Chicago *Tribune,* and in 1925 was transferred to the Rome bureau. From 1928 he devoted himself to writing. His first book was *You Can't Print That!* (1929), recording his varied experiences in parts of Europe, Asia, and North Africa, and volumes which followed included *The Truth Behind the News* (1929); *Sawdust Caesar* (1932), an attack on the Mussolini regime in Italy; *Iron, Blood, and Profits* (1934); *Freedom of the Press* (1935); *You Can't Do That* (1937); *Lords of the Press* (1938); *The Catholic Crisis* (1939); *Witch Hunt* (1940); *Facts and Fascism* (1943); *1000 Americans* (1947). From 1940 he edited *In Fact,* a weekly newsletter which obtained a wide circulation.

SELDTE, zĕl'tĕ, **Franz,** German politician: b. Magdeburg, June 29, 1882; d. Nürnberg, April 1, 1947. He studied chemistry at the Braunschweig technical high school, and on outbreak of World War I in 1914 he went on active service with the 66th Infantry Regiment. In 1916 he lost his left arm in the Battle of the Somme. Shortly after the Armistice in 1918 he founded the Stahlhelm (Steel Helmet), a semimilitary nationalistic movement, and he remained head of the organization until Adolf Hitler ordered it dissolved on Nov. 7, 1935. Meanwhile, in 1933 Hitler had appointed him minister of labor in the first Nazi Cabinet, and he retained this post until the complete collapse of the regime in 1945, surviving the vicissitudes which had swept older party members from favor. He continued as the labor minister of the German Reich in the regime of Admiral Karl Doenitz which succeeded that of Hitler. After the close of hostilities he was arrested by the Allies as a possible war criminal in connection with the use of slave labor in Nazi war industry, and was put in jail in Nürnberg. He died in an American Army hospital while awaiting trial.

SELECTION, a term in biology used in several different senses, all having reference to the process of evolution or the production of types of individuals. Artificial selection is the process which is used by breeders of animals to produce special types and qualities. See also Evolution, Theories of.

SELECTIVE SERVICE. See Conscription.

SELECTMEN, a name used in New England towns to designate executive officers corresponding to the aldermen of a city. Although customs vary, there are usually three to nine selectmen; they are elected for from one to three years. They carry out the behests of the town meetings and have minor appointive powers. The practice of choosing selectmen is found in Massachusetts as early as the issue of the *Body of Liberties.* See also Town and Town Meetings.

SELENE. See Luna.

SELENGA, sĕ-lĕng-gä', **river,** Asia, rising near Dzhibkhalantu, in western Outer Mongolia, flowing east and north through Mon-

golia and the Russian Transbaikal district, and emptying into Lake Baikal near its southern end. It is 750 miles long, and navigable for light vessels to its junction with the Orkhon. It receives through the Egin-kol the overflow of the large Lake Kosso-gol. The Selenga is the main headstream of the Angora, the principal tributary of the Yenisei.

SELENITE, the crystallized or distinctly foliated variety of the mineral gypsum, hydrous calcium sulphate. It is number two in the scale of hardness, is flexible, but when broken has a «fibrous fracture» which consists of two imperfect cleavages. When pure it is colorless and transparent. The cleavage plates have a pearly lustre which is characteristic of the clinopinacoid while the other faces of the crystal are subvitreous. Plates of selenite several feet across and perfectly transparent are not uncommon, while crystals five feet in length have been found in Utah. Fine large crystals are also found in Italy, France and Switzerland. Limpid crystals of matchless beauty occur in the Sicilian sulphur mines. Twin crystals are common in all these localities, the most typical of which are the «fish-tail» twins. Foliated selenite is abundant in Nova Scotia, also at Lockport and elsewhere in New York. while crystals of model-like perfection are found near Ellsworth, Ohio. Like massive gypsum, selenite is an exceedingly common mineral. It has been used to some extent as a filler for paper, paints, etc.

SELENIUM, symbol Se, atomic weight 79.2. It was discovered by Berzelius (1817) in the refuse of a sulphuric acid factory. A non-metallic element occupying an intermediate place between sulphur and tellurium. Occurs in the free state in small amounts usually associated with native sulphur. Found in many minerals combined with various metallic elements as copper, lead, mercury, silver, etc. Here again the compounds of selenium are found in company with the analogous compounds of sulphur. Free selenium is prepared from the compounds of selenium found in the dust depsited in the furnace flues where sulphides are burned in the manufacture of sulphuric acid. This is oxidized to selenius acid (see below) which upon treatment with sulphurous acid gives selenium.

It is found that there occurs a remarkable variation in the electrical resistance of selenium as the intensity of the light which falls upon it is varied; when the light to which selenium is exposed is increased in intensity, the electrical resistance is diminished. It is this principle that is the basis of the «Selenium Photometer» of astronomy, an instrument of extreme delicacy by which the variations in intensity of the feeble light of the stars can be measured with an accuracy which is unapproachable by any other means.

Selenium exists in two allotropic forms. The one obtained as above is a red amorphous powder soluble in carbon di-sulphide, while if this powder be melted and again cooled suddenly to 210° C. it forms a dark vitreous mass insoluble in carbon di-sulphide. Crystalline forms are also known.

In general chemical behavior it is closely related to sulphur and tellurium, all three forming analogous oxides, oxygen acids and hydrogen compounds.

Selenium Dioxide, SeO_2 a white crystalline compound formed when selenium is burned or by healing selenious acid. It dissolves readily in water forming selenious acid.

Selenious Acid, H_2SeO_3, a crystalline solid found by oxidation of selenium in presence of water, as above. It is a di-basic acid forming salts called selenites having the general formula M_2SeO_3.

Selenic Acid, H_2SeO_4, a heavy liquid resembling sulphuric acid and formed by action of powerful oxidizing agents on selenium or selenious acid. It differs from sulphuric acid in being unstable, losing its oxygen readily and thereby passing to selenious acid. Also a di-basic acid forming salts called selenates (M_2SeO_4).

With hydrogen selenium forms a very disagreeable smelling gas called seleniuretted hydrogen (H_2Se), the analogues of sulphuretted hydrogen. Selenium forms compounds with many metallic elements (see above) called selenides. These are analogous to the sulphides and usually occur along with them. They may be made by heating selenium with the metal.

SELENODONT TEETH, a type of molar teeth, characteristic of modern herbivorous animals, on which the crown of the tooth exhibits curving ridges of enamel instead of rounded tubercles. See BUNODONT.

SELENSULPHUR, an orange- to brownish mineral consisting of sulphur and selenium. It is a result of volcanic action, and occurs as an incrustation in the islands of Lipari, Vulcano, Hawaii and Japan. The name is often improperly applied to orange-yellow crystals of native sulphur from Sicily.

SELEUCIA, sĕl-ū′sĭ-ą, Asia, the name of several cities founded by Seleucus Nicator. (1) The most celebrated was SELEUCIA-ON-THE-TIGRIS, made the capital of Babylonia in place of Babylon, from which it was distant about 30 miles, and which it eclipsed in wealth and splendor. The Tigris and Euphrates flowed near its walls, and rendered it one of the richest commercial cities of ancient times. The number of its inhabitants at the time of its greatest prosperity is estimated to have been about 600,000, chiefly Greeks. During the decline of the Seleucidæ monarchy it became independent, and from its great wealth became the centre of attraction to the pillaging tribes of southern Armenia and Media, by whom it was partially plundered several times. In 116 A.D. it was burned by Trajan, and a few years later its destruction was completed by Lucius Verus, the Roman emperor. From that time it was deserted and became as desolate as Babylon itself. (2) Another important city, SELEUCIA PIERIA, founded in 300 B.C., was situated in the seacoast at the foot of Mount Pieria, 12 miles west of Antioch. Its natural strength was improved by every known art of fortification, and this combined with its magnificent buildings obtained for it a distinguished position among the great cities of antiquity. It occupied a very prominent place in the wars between the Seleucidæ and the Ptolemies, but it rapidly declined under the Roman dominion, and in the 6th century of our era the city had fallen into complete decay. (3) SELEUCIA TRACHEOTIS, a city of Cilicia on the Calycadmes, was also built

by Seleucus. It was once a rival of Tarsus, and on its site are many ancient ruins. The modern Selefke is located here. (4) SELEUCIA, a city in Persia, was founded by Alexander the Great and called Alexandria. It was rebuilt as Seleucia by Antiochus I of Syria. Among the other cities of the name were Seleucia in Mesopotamia on the Euphrates; on the Belus in Syria; in the Pisidia; and in Pamphylia.

SELEUCIDS, sē-lū'sĭds, a dynasty (312–64 B.C.) founded in Syria by Seleucus I, one of the ablest generals of Alexander the Great (r. 336–323 B.C.) and a successor to a large part of his divided empire. Seleucus I Nicator (r.312–280 B.C.) received in 321 as his share the satrapy of Babylon, from which he conquered eastward (311–302 B.C.) as far as the Indus. Consequent to his victory at Ipsus (in Great Phrygia, 301 B.C.) over Antigonus I (r.306–301 B.C.), king of Macedonia and another general and successor of Alexander, he added Syria and eastern Asia Minor. In northern Syria he established Antioch, so named after his father, which became the capital of the kingdom. He also founded several cities named Seleucia after himself, chief among which was Seleucia-on-the-Tigris, which served as the capital of the eastern satrapies. These cities were peopled by Macedonian and Greek colonists, enjoyed civic independence, and developed into important centers for the diffusion of Greek language and culture. Educated Syrians began to study Greek and write in it, but the countryside retained its old speech and its way of life. Next to colonization, the establishment of a standard calendar for western Asia was perhaps the greatest achievement of the period. The year 312 B.C. is reckoned as marking the birth of the Syrian monarchy and the starting point of the Seleucid era. The era, called Greek by Syrians and Jews, began October 1 and is still in limited use today.

The kingdom established by Seleucus was hardly ever at rest. His immediate successors Antiochus I Soter (r.280–261 B.C.) and Antiochus II Theos (r.261–247 B.C.), fought indecisively against Ptolemy II Philadelphus (r.285–246 B.C.), king of Egypt and son of another general and successor of Alexander, for the possession of Palestine. Antiochus III the Great (r.223–187 B.C.) reconquered the Iranian territory as far as India and carried Seleucid arms almost to the Egyptian border. But his attempt to conquer Greece brought him into conflict with Rome, to which he was forced to cede all the territory beyond the Taurus Mountains and to pay a heavy war indemnity. In his wars he made effective use of the elephant. This animal became a Seleucid emblem and figured on the coins. Apamea-on-the-Orontes (Afāmiyah, Qal'at al-Maḍiq) served as a depot where war elephants, mostly imported from India, were bred and trained.

Of the remaining sovereigns—there were about 26 in all—one of the best known was Antiochus IV Epiphanes (r.175–163 B.C.), whose invasion of Egypt (169 B.C.) resulted in the occupation of its lower part. As an enthusiastic champion of Hellenism, he tried to impose its culture upon his subjects, particularly the Jews of Palestine, thus provoking the Maccabean revolt (?166 B.C.). The spoils of the Temple of Jerusalem helped to finance his lavish program of public buildings. Among his successors Antiochus V Eupator (r. 163–162 B.C.) was feeble and corrupt; Alexander Balas (r.150–145 B.C.) was dissolute; and Demetrius II Nicator (r.145–138, 129–125 B.C.) could not hold his own against the Parthians. Antiochus VII Sidetes (r. 139–129 B.C.) restored the royal line and carried on war against the Jews, who were enjoying a period of independence under the Maccabees (165–134 B.C.). So weak had the Seleucid state become that Tigranes, king of Armenia (83–69 B.C.), ventured to invade Syria and penetrated (69 B.C.) as far south as Acre (Ptolemais). Five years later Pompey the Great (106–48 B.C.), the Roman general, appeared on the scene, overthrew Antiochus XIII Asiaticus (r.69–64 B.C.) and organized Syria into a Roman province. By that time Bactria, Parthia, Armenia, and Judaea had been lost.

Syria was the backbone of the Seleucid kingdom. Syrian trade, both domestic and foreign, was of great consequence to the entire realm and to its population. It was the Seleucid policy to promote commercial relations with the Graeco-Roman world. The main inland highways were guarded by chains of strong colonies, which also provided adequate halts for the caravaneers. Dura-Europos, founded c.300 B.C. by Seleucus I on the desert road between Syria and Mesopotamia, was such a colony and soon developed from a strong fortress to an important emporium.

The political institutions of the Seleucid realm were a strange mixture of Greek and Near Eastern elements. The king not only enjoyed absolute power, but also was surrounded by a divine halo of Oriental origin. Some of the late kings, like Balas (from Ba'l, lord [name of a deity]), assumed Semitic titles. The language of the court was, of course, Greek. Both army and navy were the king's. In its early stages the army consisted of Macedonians and Greeks recruited from the realm. Its nucleus was the phalanx. While the fleet at no time played a decisive part in any of the recorded battles, yet it performed a useful function in cooperating with the active army and in protecting military transport; it was manned mostly by Phoenicians.

Professor of Semitic Literature, Princeton University.

SELF-CONSCIOUSNESS, the conscious recognition that one is an ego or personality: distinguished from consciousness (q.v.). In the article in this encyclopedia on consciousness, it is treated from the material point of view. Self-consciousness here will be treated from the occult or Eastern viewpoint. Each one of us is conscious of himself as an identity or unit, different from every other individual. We know this as fundamentally as we know anything, and while we cannot prove to any of our five senses just what this identity is, this does not militate against the fact of its being a truth. The five senses inform us of material outside things, which science has catalogued and philosophy reasoned upon; but self-consciousness comes to us as an intuition, being recognized in the same way as that which we call conscience, which may be defined as a phase of self-consciousness. It is characteristic of this

self-consciousness that it instinctively knows right from wrong, and thus tends to a recognition of morality as the way of evolution. That the consciousness of all men is in a stage of evolution is easily reasoned out. The babe has a very dim consciousness, and hence little responsibility. The drunkard or dope fiend has reduced his consciousness, and we hold him to be little accountable for what he does under such conditions. The wise man is one who has opened his consciousness to a great many things, and we expect much more of such a one and hold him to a much higher responsibility. It is not too much to say that the destiny or forward movement of the race seems to rest mainly with its wise men, those who are wise in morals as well as science. We cannot set our ideals any higher than what we can conceive of; in fact man appears to be ever setting his ideals above his actions, never quite as good or as clever as he could wish; and when he improves he sets his ideals yet higher, and so never reaches them. This condition is named the development of consciousness. There comes a time in the progress of every man when he realizes that he is higher and apart from matter — and this is true even if men have not yet attained to that realization. We are not mere animals, but are imbued with a life principle and a higher force which is higher even than the human mind. The proof of this is that a few men and women have learned to control their minds, to concentrate on a fixed point until the active mind is absolutely stilled. Any person of good intelligence can do this with practice, if he have the will and the patience, for it takes a great deal of both. That which is highest in man — call it the soul, the Divine spark, the ego or what you will — is designed to govern both the mind and body. The majority of people have little government over their bodies, and a still smaller fraction have definite control over their minds. Yet all truly great men do rule both their appetites and their minds, for thus can they rise far above the crowd and accomplish the things for which we call them great. But the self-conscious individual is one who has come to recognize this divinity of the higher nature, this attribute of the God within, and who is striving to evolute to still higher paths of usefulness, that he may serve humanity. For it is a characteristic of those who have attained the greatest degree of self-consciousness that they discover nothing higher in the way of accomplishment than the service of mankind; and if they give time and effort to developing themselves it is that they may be the more fit to serve their fellows. The intellectual materialist who has not proceeded far on the way toward self-consciousness will probably challenge some of these statements because he has not experienced them, and what he has not felt he refuses to accept, as if it were possible for any one man to have all experiences or all knowledge. These sort of truths are taught by all grades of philosophers from ancient to modern times. But without depending upon authority, each of us can ask himself the question, "What is this within me that I call *I*? — that sits in judgment on my acts? — that impels me toward higher things, and condemns me when I yield to lower desires?" This it is that is here characterized as self-consciousness. The more I consult it, the more I listen to its voice, the more plainly it speaks, and it always teaches unselfishness and morality. When it is listened to, it informs a man of his faults, and thus assists him in curing them. To those who study their own consciousness it reveals other things — that they have faculties and powers, and that these appear supreme in their own domain. In other words, a man has will, which is his own, and choice, of which no one can deprive him. Will and choice send one man in search of the North Pole, another to the forefront of a battle, another to the bedside of the dying, another to the accumulation of wealth, another to a study of the stars, another to investigation of the laws of electricity, and so on *ad infinitum*. It is these qualities of finite godship which lead many to the conclusion that man is a spark of the Divine, and bound to evolute forever; that while he has freedom of will and choice for good or evil, he is never free from the hyperphysical superior will of good (or God) which always overcomes evil. Consult Steiner, 'The way of Initiation' (English trans., New York, 1910); Besant, 'A Study in Consciousness' (1900); Hudson, 'Evolution of the Soul'; Judge, 'Culture of Concentration' (1885).

CHARLES H. COCHRANE.

SELF-DEFENSE is the right to protect one's person or property from injury. The law further sanctions the mutual and reciprocal defense of those who stand in the near relation of husband or wife, parent or child. It is lawful to repel unlawful force by force, for the fundamental law in such cases is that one has a primary right to stop injury to oneself, to one's family, or those who rightfully look upon one as a protector. But it is an essential principle of law that we must not use more force than is necessary for self-defense. The law of self-defense is founded on necessity, and one in order to avail himself of this defense in law must show belief, and the reason to believe, that there was imminent danger to life, or of receiving bodily harm, and that as a reasonable person no other means of defense would be effectual; the danger must be apparent and imminent and either existing at the very time, or reasonably believed to be so. Threats alone do not justify or excuse homicide; there must be some actual demonstration of an intent to take life, or inflict bodily harm in order to establish self-defense to the extent of taking a life. In cases of mere assault it is generally held that the right of self-defense does not arise until reasonable effort has been made for protection. One who is in legal possession of property has the right to defend the same against one who manifestly intends or endeavors by violence to commit a felony, and may under certain exigencies in such defense kill his adversary. (See MANSLAUGHTER). An officer of the law authorized to make an arrest has the right to use necessary force, and if the person whom he is attempting to arrest, by resistance, brings violence upon himself, this cannot be made to justify the killing of an officer. In many of the States the principles of law respecting right of self-defense is the subject of statutes. (See ASSAULT; CRIMINAL LAW; MURDER; HOMICIDE). Self-defense in boxing is termed the "manly art." it being held that it is every man's

duty to know how to defend himself with his natural weapons in case of assault.

SELFRIDGE, sĕl'frĭj, **H(arry) Gordon,** Anglo-American merchant: b. Ripon, Wis., probably on Jan. 11, 1864; d. Putney, London, England, May 8, 1947. Educated in the public schools of Jackson, Mich., Selfridge joined Field, Leiter and Company (subsequently Marshall Field and Company) in 1879 and rose rapidly to a junior partnership, retiring in 1903 with a substantial fortune. After re-entering business briefly in Chicago, he went to England in 1906 and in 1909 opened a large department store, Selfridge and Company, in London, which by skillfully blending American advertising and merchandising methods with English needs and habits became an immediate success. Selfridge wrote *The Romance of Commerce* (1918) and essays published in *Callisthenes* (1933). *Florentine Merchants in the Age of the Medici* (1932), ed. by G. R. B. Richards, is based on his collection of Medici manuscripts. He became a British subject in 1937.

SELIGMAN, sĕl'ĭg-măn, **Joseph,** American financier: b. Baiersdorf, Bavaria, Nov. 22, 1819; d. New Orleans, La., April 25, 1880. Dissatisfied with the lack of opportunities for Jews in Germany, Seligman emigrated to the United States as a young man in 1837, and within a decade was followed by his seven brothers, all younger. After being employed for some time by Asa Packer, the Pennsylvania financier, Joseph went into business at Lancaster, Pa., with his brothers William and James, and with them later opened a dry goods store at Greensboro, Ala. In 1848 they moved to New York, N. Y., and this city became the headquarters of a family clothing and importing business which by 1857 had been joined by all seven brothers under Joseph's leadership.

The firm supplied a great volume of clothing to the army during the Civil War, and in 1862 it was transformed into a banking house, J. & W. Seligman & Company. Headquarters were in New York, but branches, each in charge of a brother, were soon opened at San Francisco, New Orleans, Frankfurt am Main, London, and Paris. The European branches, especially the one at Frankfurt, rendered valuable service during the Civil War by marketing hundreds of millions of dollars' worth of United States government bonds abroad. Joseph Seligman subsequently became a confidential financial adviser to President Grant, a personal friend of the family, and the firm played a leading role in handling the conversion operations of government bonds during the 1870's. Seligman was one of the Committee of Seventy that helped free New York City from the grasp of the Tweed Ring.

One of his brothers was Jesse Seligman: b. Baiersdorf, Bavaria, Aug. 11, 1827; d. Coronado, Calif., April 23, 1894. He reached the United States in 1841 and worked with his brothers in dry goods stores in the East. After the gold rush had begun, Jesse went to California with his brother Leopold in 1850 and opened a store in San Francisco. Here he amassed a considerable sum which he contributed to the family business upon his return to New York in 1857. Jesse succeeded Joseph in 1880 as head of J. & W. Seligman & Company, which under his leadership became active in floating securities for railroads in the South and Southwest.

Jesse Seligman was succeeded as head of the family firm in 1894 by a son of Joseph, Isaac Newton Seligman (b. Staten Island, N. Y., July 10, 1855; d. New York, N. Y., Sept. 30, 1917), under whom the company floated numerous loans for countries in Latin America and the Orient.

Another son of Joseph was the economist Edwin Robert Anderson Seligman: b. New York, N. Y., April 25, 1861; d. Lake Placid, N. Y., July 18, 1939. He studied at Columbia University (A.B. 1879, Ph.D. 1885) and taught there from 1885 until his retirement as professor emeritus in 1931. Seligman edited the *Political Science Quarterly* (from 1886) and was editor in chief of the monumental *Encyclopedia of the Social Sciences.* An expert on public finance, keenly interested in public affairs, he served on several tax commissions and was financial adviser to the Cuban government in 1931. Among his many books are *The Shifting and Incidence of Taxation* (1892), *Essays in Taxation* (1895), *The Economic Interpretation of History* (1902), and *Principles of Economics* (1905)—all of which went through numerous editions—and *Currency Inflation and Public Debts* (1921), *Studies in Public Finance* (1925), *The Economics of Farm Relief* (1929), and *Price Cutting and Price Maintenance* (1932).

SELIM I, sĕ-lēm', Turkish sultan: b. 1467; d. Sept. 20, 1520. He was a son of Bajazet II, whom he dethroned (1512) during a struggle in which he overcame his brothers Corcud and Ahmed. The Persian Shah Ismail I had been Ahmed's ally, and before proceeding against him, Selim, a Sunnite Muslim, is said to have slaughtered 40,000 of his Shi'ite subjects, who were the Persians' coreligionists and perhaps in sympathy with them. Ismail was completely defeated at Chaldiran in Armenia on Aug. 23, 1514, and Selim captured Tabriz.

The Mameluke sultan of Egypt, Qānṣawh al-Ghawri, whom Selim accused of being allied with Ismail, was overwhelmed by Selim's Turks, well equipped with muskets and artillery, at Marj Dābiq, north of Aleppo, on Aug. 24, 1516. Syria then fell into Turkish hands, and in January 1517 Selim captured Cairo, adding Egypt to the Ottoman domain. Selim transferred to Constantinople the puppet Abbasid caliph whom the Mamelukes had maintained at Cairo, and the caliphal privileges and finally the title were absorbed by Selim's successors. Even more important, the holy cities of Arabia acknowledged the Ottoman sultan as their protector. Selim was succeeded by his son Suleiman I.

SELIM II (called Selim the Sot), Turkish sultan: b. probably in 1524; d. Dec. 12, 1574. He was the son of Suleiman I, whom he succeeded in 1566. Engrossed in the pleasures of his court, Selim relied principally on two remarkable counselors: Mohammed Sökölli, grand vizier from 1560 to 1579, whose policy was pro-Venetian and anti-Spanish; and a Portuguese Jew, the financier Joseph Nasi (João Miguez, c. 1515–1579), who was anti-Venetian and anti-French. During Selim's reign the Turks captured Tunis from Spain in 1569 (lost to Spain in 1573, but recovered in 1574); took Cyprus from the Venetians in 1570–1571; but suffered

defeat in the naval battle of Lepanto (1571), which ended Nasi's influence. Selim was succeeded by his son Murad III.

SELIM III, Turkish sultan: b. 1761; d. Constantinople, July 28, 1808. He was the son of Mustafa III and succeeded his uncle Abdul-Hamid I in 1789 during the war with Russia and Austria. After this conflict ended in the Treaty of Jassy (1792), Selim began a determined effort to reform the Ottoman state, particularly the finances and armed forces. But although he raised a small corps armed and trained in the European fashion, little was accomplished because of resistance by the Janissaries and religious leaders and the inertia of a ponderous administrative system.

Egypt, occupied by the French under Napoleon in 1798, was returned to Turkey in 1802. Continued Russian expansion led to a *rapprochement* between Selim and Napoleon and to war with Russia in 1806. In 1807, however, the sultan was overthrown and imprisoned by a rising of the Janissaries, who replaced him with Mustafa IV. Selim was strangled upon the approach of loyal forces under Mustafa Bairakdar, who captured Constantinople and raised to power Selim's nephew and pupil Mahmud II.

SELINSGROVE, sē'lĭnz-grōv, borough, Pennsylvania, on the Susquehanna River in Snyder County, 36 miles north of Harrisburg. The borough manufactures hosiery, paper products, and tools. Susquehanna University, founded in 1858, is here. Selinsgrove was settled in 1755 and incorporated in 1827. Pop. (1950) 3,514.

SELINUS, sē-lī'nŭs (Ital. SELINUNTE), ancient Greek city, Sicily, on the southwest coast, now an isolated site about eight miles south-southeast of Castelvetrano. It was founded in the 7th century B.C. and flourished during the 5th century. Its traditional enemy, Segesta, after receiving ineffective aid from Athens, called in the Carthaginians, who sacked Selinus in 409 B.C. It never recovered, though it became a Carthaginian tributary and was quickly repopulated. In 250 B.C. the Carthaginians razed the city and moved the inhabitants to Lilybaeum (now Marsala). The remains include temples, walls, and an acropolis, none in a good state of preservation.

SELJUKS, sĕl-jōōks', originally Turkoman tribesmen, who in the 10th century fought their way into western Asia and established dynasties in Persia, Mesopotamia, Syria, and Asia Minor. Tradition derives the name from Saljūq, the chieftain of a Ghuz (Ghuzz) tribe which had settled in the Bukhara region and embraced Islam, of the Sunnite variety.

Great Seljuks.—The history of the Seljuks assumes major importance in 1055 when Tugrul (Tugril Beg), grandson of Saljūq, having pushed his conquests through Persia, entered the Abbasid capital, Baghdad, and was received by the caliph al-Qā'im (r. 1031–1075) as a deliverer from the domination of a Persian Shi'ite dynasty, the Buwayhids. Al-Qā'im bestowed on Tugrul the title of sultan ("he with authority").

Tugrul was succeeded by his nephew Alp Arslan (r. 1063–1072), who in 1071 inflicted a crushing defeat on the Byzantine army at Manzikert (Malazkirt), opening Asia Minor to an influx of Turkomans and Turks, in whose hands it has remained.

Alp's son and successor, Malik Shah (r. 1072–1092), who was ably served by his illustrious Persian vizier, Nizam-al-Mulk, ruled a sultanate extending from Afghanistan to the Byzantine borders and is considered the greatest of his line. During his reign the frontiers were extended by various chieftains to Syria, Palestine, and western Asia Minor; new roads were opened, mosques built, canals dug, and large sums expended on caravanserais. After Malik Shah's death, civil wars among his sons and other disturbances led to the breakup of his house, although the main line, the Great Seljuks, maintained a nominal suzerainty in Persia down to 1157.

Syrian Seljuks.—The founder of Seljuk power in Syria was Tutush, son of Alp Arslan, who gained possession of Aleppo in 1094. His sons ruled at Aleppo and Damascus. Various Seljuk dynasts ruled in North Syria from 1078 to 1171.

Rum Seljuks.—More important than the Seljuks of Syria were the Rum (that is, Roman or Western) Seljuks who ruled in Asia Minor from 1077 to about 1300, becoming independent with the decline of Great Seljuk power. This branch was founded by Suleiman ibn-Qutulmish, a cousin of Alp Arslan, who was put in charge of the conquered territory and established himself at Nicaea (now İznik), not far from Constantinople, in 1077. The Rum Seljuk capital was moved to Iconium (Konya) in 1084.

Hemmed in between the Byzantines on the northwest and the states the Crusaders established at Antioch (Antakya) and Edessa (Urfa) on the southeast, the Rum sultanate was limited to central Asia Minor. Nevertheless, trade flourished with the Italian merchant republics and the kingdom of Little Armenia in Cicilia, and sultans and princes vied in building mosques, madrasahs (mosque schools), and other public buildings which still attract students and visitors. Gradually, however, Asia Minor became partitioned into rival petty principalities, which were overcome by the Mongol onslaught in the mid-13th century. One of these principalities was that of the Ottoman Turks, cousins of the Seljuks and, beginning with the 14th century, their heirs.

PHILIP K. HITTI,
Princeton University.

SELKIRK, sĕl'kûrk, or **SELCRAIG,** sĕl'krāg, **Alexander,** Scottish sailor, the original of Daniel Defoe's Robinson Crusoe: b. 1676; d. Dec. 12, 1721. The son of a shoemaker of Largo, Fifeshire, he was an experienced seaman when, in May 1703, he joined William Dampier's privateering expedition to the South Seas as sailing master on the *Cinque Ports.* After quarreling with his captain, Thomas Stradling, Selkirk was marooned at his own request on uninhabited Más a Tierra Island of the Juan Fernández group in October 1704, remaining there until he was taken off by the *Duke* of Woodes Rogers' expedition in February 1709. He died a master's mate on H.M.S. *Weymouth.* Selkirk's stay of more than four years on Más a Tierra was described by Richard Steele in the

Englishman (No. 26; Dec. 3, 1713), in Rogers' *Voyage Round the World* (1712), and in Cook's *Voyage to the South Sea and Round the World* (1712); but there is no reason to believe that he had any papers or journal of any sort. He is known as the prototype of the *Robinson Crusoe* (1719) of Daniel Defoe (q.v.), who apparently derived such information as he had from Steele, Woodes Rogers and Edward Cooke. Little of the details of the famous narrative, however, is derived from Selkirk's adventure.

SELKIRK, 5TH EARL OF (THOMAS DOUGLAS): b. Kirkcudbrightshire, Scotland, June 20, 1771; d. Pau, France, April 8, 1820. He was educated at Edinburgh University, and in 1799 succeeded his father in the earldom. He was active in the promotion of the emigration movement to the Red River and the colony established there was known as the Earl of Selkirk's Settlement. He published *Sketch of the British Fur Trade in North America* (1816); *The Red River Settlement* (1817).

SELKIRK, town, Province of Manitoba, Canada, on the Red River of the North, 23 miles north-northeast of Winnipeg, and on the Canadian Pacific Railway. The town is a popular summer resort. Its fisheries are of considerable importance. There are large cold storage plants, government shipyards and dry docks; mental hospital. Pop. (1951) 6,218.

SELKIRK MOUNTAINS, or **SELKIRKS,** range of the Rocky Mountains, in British Columbia, from about latitude 52° to 48° N. The Columbia River is on the eastern side for some distance, and the Canadian Pacific Railways crosses the range between the peaks Sir Donald (highest peak, 11,123 feet), and Glacier House at an altitude of 4,300 feet.

SELLERS, sĕl'ĕrz, **Coleman,** American engineer: b. Philadelphia, Pa., Jan. 28, 1827; d. there, Dec. 28, 1907. He obtained a degree at Stevens Institute of Technology, and was professor of engineering practice there from 1886. He was chief engineer of the Niagara Falls Power Company, and chief mechanical engineer of the Canadian Niagara Power Company. He made numerous inventions in mechanical appliances, was a member of many American and foreign scientific societies, and was widely known as a consulting engineer.

SELLERS, David Foote, United States naval officer: b. Austin, Texas, Feb. 4, 1874; d. Bethesda, Md., Jan. 27, 1949. Appointed to the Naval Academy from New Mexico in 1890, he was graduated with distinction in 1894 and advanced through the grades to rear admiral in 1927. He held the rank of admiral, retired, after July 16, 1942. Some of his more important posts include: flag lieutenant and aide to commander in chief of the Atlantic Fleet (1905–1907); executive officer, U.S.S. *Arkansas* (1914); commanding officer, U.S.S. *Salem,* and later U.S.S. *Birmingham* (1915); aide to secretary of the navy (1921–1922); commanding officer, U.S.S. *Maryland* (1922–1923); commanding officer of naval training station at San Diego, Calif. (1923–1926); chief of staff of the commander of the Scouting Fleet (1926–1927); commanded special service squadron of five cruisers off Nicaragua (1927–1929); judge advocate general of the navy (1929–1930); commander of Battleship Division I of Battle Fleet (1931); commander of battleships, Battle Fleet (1932); commander in chief of the United States Fleet (1933–1934); superintendent of the U.S. Naval Academy (1934–1938).

SELLERS, Matthew Bacon, American aeronautical engineer: b. Baltimore, Md., March 29, 1869; d. Ardsley-on-Hudson, N. Y., April 5, 1932. He was educated in France and Germany, took his LL.B. at Harvard University in 1902, and later studied at the Lawrence Scientific School, Harvard, and at the Drexel Institute, Philadelphia He was engaged in aerodynamic research after 1900; was appointed a member of the Aerodynamic Laboratory Committee by President Taft in 1912; and in 1915 became a member of the Navy Consulting Board. He was the first to determine the lift and drift of arched surfaces by means of the wind tunnel; and inventor of the lightest aeroplane in the world. From 1911 to 1932 he was technical editor of *Aeronautics.*

SELLERS, William, American mechanical engineer and manufacturer: b. Upper Darby, Pa., Sept. 19, 1824; d. Jan. 24, 1905. He was apprenticed to a machinist, and in 1848 became a member of the firm Bancroft and Sellers, which in 1855 became William Sellers and Company, manufacturers of tools. He made many improvements in tools and invented many new appliances. He suggested the first formula ever offered for screw threads and nuts, which has since become standard in the United States and Europe. He was president of Franklin Institute in 1864–1867. He became president of the Edge Moor Iron Company in 1868, and in 1873–1887 directed the Midvale Steel Company, Nicetown, Pa., manufacturing materials for small arms and ordnance for the government. He was elected to the National Academy of Sciences in 1873.

SELLERS, Colonel Mulberry, the name of a character in the novel, *The Gilded Age* (1873), by Mark Twain and Charles Dudley Warner. He was a visionary Southern speculator, and was created on the stage by John T. Raymond.

SELLSTEDT, sĕl'stĕt, **Lars Gustaf,** American painter: b. Sundsvall, Sweden, April 30, 1819; d. Buffalo, June 4, 1911. He came to the United States in 1834, and subsequently served in the United States Navy. After settling in Buffalo, 1842, he devoted himself to a study of art, and in 1875 was elected a National Academician. He was one of the founders of the Buffalo Fine Arts Academy and was one of its directors for 26 years. His autobiography, *From Forecastle to Academy,* was published in 1905.

SELMA, sĕl'mà, city, Alabama, Dallas County seat, altitude 126 feet; on the north bank of the Alabama River, with year-round navigation; on the Southern; Louisville and Nashville; and Western of Alabama railroads; by rail, 10 miles south of Birmingham, 162 miles northeast of Mobile; also served by a municipal airport, and federal and state highways. River steamers and barges provide a means of transportation for shipments to and from Selma, complementing the railroads and truck service on the highways.

Situated in what is known as "the black soil belt," Selma is surrounded by a rich agricultural

region, producing cotton, livestock, and forage crops. Cotton, lumber, and food crops are the principal bases of the city's industry. Products of Selma plants are lawn mowers, candy, canning, cigars, creameries, meat packing, and fertilizers.

Besides public and parochial schools, the city has several business colleges and Selma Univercity, a Baptist school for Negroes. It has a Carnegie library, more than 40 churches, three hospitals, and a children's home. The Craig Air Force Base, established in 1940, and located 4½ miles southeast of Selma, later became part of the United States Air University, but is now under the Training Command. In the Civil War, Selma was the site of a Confederate navy yard. Pop. (1940) 19,834; (1950) 22,629.

SELMA (Ala.), **Battle of,** an engagement of the Civil War, April 2, 1865, one of the battles of General Wilson's cavalry raid in the operations against Mobile. The Union cavalry camped at a point 19 miles north of Selma on April 1 and on the morning of the next day began the movement against the town. One division advanced from the north on the Sumnerville road, and a second division from the northeast on the Burnsville road, while a third division was dispatched to burn railroad bridges, trestles, stations, etc., as far as Burnsville. The troops were in position before Selma by 4 P.M. and, dismounting, assaulted and carried the works at a single charge, the distance over which they charged, exposed to the enemy's fire, being 600 yards. The Selma fortifications consisted of a bastion-line with a radius of three miles; the Confederate force on the line against which the charge was made was over 1,500; the Union force engaged numbered 1,550. The Federals captured 31 field guns, a large number of prisoners, and quantities of stores of all kinds.

Consult Johnson, R. V., and Buel, C. C., *Battles and Leaders of the Civil War,* 4 vols. (New York 1884–1888).

SELOUS, sĕ-lōōs′, **Frederick Courteney,** famous big game hunter and explorer: b. London, Dec. 31, 1851; killed in action, East Africa, Jan. 4, 1917. Of mixed French, English and Scottish parentage, he was educated at Rugby, Neuchâtel and Wiesbaden, and at 19 set out for Africa to become an elephant hunter. After spending a time on the Kimberley diamond fields he entered the wild Matabele territory (now Southern Rhodesia) and obtained permission from the savage chieftain Lobengula to carry out his object. By the time he was 25 Selous was known as the most daring and successful ivory hunter in Africa. Nor did he restrict his activities to elephants alone; lions, hippo and rhinoceroses fell to his unerring rifle. In 1889 he traveled down the Zambesi to the sea and in 1890 led the pioneer expedition of the Chartered Company into Mashonaland and secured that territory for Britain. He fought in both the Matabele wars, and in later life resumed his hunting adventures. In 1909–1910 he organized and accompanied Colonel Roosevelt's hunting expedition in British East Africa. Though over 60 years of age he offered his services for the war; was gazetted lieutenant in the Royal Fusiliers in 1915, and captain a few months later. In September 1916 he received the D. S. O. "for conspicuous gallantry, resource and endurance."

Selous wrote *A Hunter's Wanderings in Africa* (1881), a book regarded as a classic on hunting; *Travel and Adventure in Southeast Africa* (1893); *Sunshine and Storm in Rhodesia* (1896); and *Recent Hunting Trips in British North America* (1907).

SELUNGS, sĕ-lŭngs′, a race of men, now few in number, and of doubtful affinities, but usually classified as Indonesian, inhabiting the Mergui Archipelago and other islands along the eastern coast of the Bay of Bengal. They live almost wholly in boats made of palm-leaf ribs sewed together by threads of coir and subsist almost exclusively on seafood, to which fact is attributed the prevalence of leprosy among them. Their principal industry is the gathering of edible birds' nests from the towering cliffs of granite by means of immensely long bamboo ladders. They also gather some mother-of-pearl and other salable shells with which they occasionally come to the ports on the mainland to trade for cloth, etc. They are despised by both the Burmese and Malays, with whom they most often come into contact.

SELVAGE, sĕl′vĭj, the edge of a woven fabric. *In mining,* selvage is a layer of clay or decomposed rock along the wall of a vein.

SELWYN, sĕl′wĭn, **Alfred Richard Cecil,** Canadian geologist: b. Kilmington, Somerset, England, July 28, 1824; d. Vancouver, British Columbia, Canada, Oct. 18, 1902. In 1845 he was appointed assistant on the Geological Survey of Great Britain, and in 1852 director of the Geological Survey of Victoria, Australia, which was not completed until 1869, when he was appointed director of the Canadian Geological Survey, completed in 1895. He also investigated the coal and gold fields of Tasmania in southern Australia in 1854–1859. He was a fellow of the Royal Society, was made an honorary LL.D. by McGill University, and was created C.M.G.

SELWYN, sĕl′wĭn, **George Augustus,** English wit and politician: b. Gloucestershire, Eng., Aug. 11, 1719; d. London, Jan. 25, 1791. He was educated at Eton and Oxford, but quitted Oxford before graduating on account of a reputed insult to the Christian religion. He was appointed to several offices at the mint involving no work and bringing him a small salary. In 1747 he entered Parliament for Ludgershall and from 1754 to 1780 sat for the city of Gloucester. He never spoke at Parliament, but his vote being always cast with the court party secured him lucrative appointments. He was a famous wit at the clubs and an intimate of the duke of Queensberry, Horace Walpole and Lord Carlisle.

SELWYN, George Augustus, English bishop: b. Church Row, Hampstead, Eng., April 5, 1809; d. Lichfield, April 11, 1878. He was educated at Eton and at Cambridge; rowed in the first interuniversity boat race (1829). His remarkable powers as an athlete were found very serviceable in after life. In 1841 he was consecrated bishop of New Zealand and Melanesia, a territory since then divided into seven dioceses. On the voyage out he studied Maori and navigation and in his own vessel visited every portion of his diocese before setting about the work of organizing it. A visit to England in 1854 brought back John Coleridge Patteson, afterward bishop of Melanesia, where he was murdered by the na-

tives. In 1868, while in Britain attending the first Pan-Anglican Synod, at Lambeth, he accepted the vacant bishopric of Lichfield. Through public subscription, Selwyn College (q.v.) was established at Cambridge University in 1882 as a memorial to him.

SELWYN COLLEGE, Cambridge, England, was founded in 1882 in memory of George Augustus Selwyn (q.v.), bishop of Lichfield. It is an institution meeting the requirements of Anglican theological students, on a more economical basis than those of the older established colleges, "combined with Christian training according to the principles of the Church of England."

SEMANTICS, (1) the science of word meaning and (2) a system of speech analysis intended to promote more exact expression and assure better understanding. The word comes from Greek *semantikos,* signification, and in modern usage replaces the earlier word *semasiology.* The modern semantician studies the history and present status of words; analyzes their value and force; and combats the tendency to ambiguity inherent in the nature of language and the mind. He stresses the fact that words do not have a single fixed, unalterable meaning, and classifies them by the purpose and manner of their use. He studies figures of speech, multiple meanings, the importance of context, the art of defining, and the nature of words. In connection with semantics, a system called Basic English has been promoted; it rests upon the theory that English can best be taught, learned, and improved by use of a selected vocabulary of essential (basic) words. See Basic English; Language, Science of—*Semantics.*

SEMAPHORE, a signaling device; originally a set of arms pivoted upon a post, used by the French for transmitting messages over long distances. Mounted on towers at intervals of 5 to 10 miles, read by telescope and passed on from station to station, they provided a means of communication previously unmatched in speed. In 1816 the British Admiralty adopted a similar system with apparatus embodying some improvements suggested by Sir Home Riggs Popham; two arms were used instead of six, and they were pivoted in such a manner as to give 48 separate letter and digit signals, and capable of sending in any direction instead of on one fixed line. Dispensing with pivoted arms on a post, in military and naval usage men also semaphore with their arms, generally holding small flags to make the signals clearer. The semaphore post is used in railway signaling, and in some highway traffic systems. See Block and Other Railway Signal Systems.

SEMARANG, sĕm-ä-räng′, Netherlands Indies, a seaport town on the north coast of Java, at the mouth of a river of the same name, 255 miles east of Batavia. The river is silted up at its mouth, but a canal, constructed in 1879, serves as a harbor. Although high seas during the monsoon season render the port unusable for several weeks each year, Semarang is the most important trade center of central Java. Ten per cent of all the imports and five per cent of all exports of the Netherlands Indies pass through the port. It has had rail connection with other towns on the island since 1873; and it is also connected with Batavia and Soerabaja by air transport services. Pop. 223,000 (13,000 whites; 210,000 Indonesians).

SEMBRICH, zĕm′brĭk, **Marcella** (real name Praxede Marcelline Kochanska, kô-kän′y-skä), operatic soprano: b. Lemberg, Austria (later Lwów, Poland), Feb. 15, 1858; d. New York City, Jan. 11, 1935. The daughter of Kasimir Kochanski, a Polish musician, she adopted for her stage name the maiden name of her mother. She studied piano at the Lemberg Conservatory under Wilhelm Stengel, whom she married in 1877. After making her debut at Athens, Greece, in 1877 as Elvira in *I Puritani,* she studied for a while under Richard Lewy, and in October 1878 made a highly successful appearance at Dresden, Germany in the title role of *Lucia di Lammermoor.* In June 1880 she made her first appearance at Covent Garden, London, again singing the part of Lucia; subsequently she sang other roles in London, and returned to that city for the seasons 1881–1884. In 1883 she sang at the Metropolitan Opera House, New York City, and she was leading soprano there from 1898 until her retirement from opera in 1909. She often appeared on the concert stage, and continued her concert work in the United States until 1917. Subsequently she was a successful voice teacher, from 1924 heading the vocal department at the Curtis Institute, Philadelphia, Pa. Her voice, adapted to every type of lyric and coloratura music, had a range from the C below the treble clef to F above it.

SEMECARPUS, a genus of trees of the Anacardiaceae, containing about 35 species. The marking-nut tree (*S. anacardium*) is the most important species. The pericarp of its fruit furnishes a juice greatly used in India for printing cotton cloth, for ink, and for dye. It is also employed for warding off white ants and for a medicine in rheumatism, warts, and leprosy. When pounded and boiled in rape-seed-oil it stays putrefaction when started in hides. The seed itself, which is called Oriental cashew-nut or melacca bean, and the fleshy pedicel, are eaten by the natives. The resin of this species yields Sylhet varnish, and an oil derived from it, mixed with the milk of euphorbia, is made into birdlime. This species is cultivated to a limited extent in southern Florida.

SEMELE, sĕm′ŭ-lê, in Greek mythology, daughter of Cadmus, king of Thebes, beloved by Zeus. Hera, prompted by jealousy, persuaded her to ask of Zeus that he should appear before her in all his glory. Zeus unwillingly consented, and in the lightning, which was the symbol of his majesty, Semele was consumed, after giving birth to a son by Zeus, the god Bacchus or Dionysus. The latter found his mother in Hades and took her to Olympus.

SEMIAUTOMATIC GUNS. See Ordnance.

SEMINOE DAM. See Dams.

SEMINOLE (sĕm′ĭ-nōl) **INDIANS** (Creek Simanoli, "separatist," "renegade"). An important tribe of the Muskhogean stock of American Indians. The name was originally applied

to those Creeks and Hitchitis on lower Chattahoochee River who left the main body about 1762–1768 and removed to the peninsula of Florida. Previously the territory had been occupied by the Appalachis who were practically exterminated some 60 years before, although some Creeks, who later became part of the "Seminoles," have resided in the southern part of Florida since the middle of the 16th century. The separation of the Creeks and Hitchitis from their northern kinsmen was due chiefly to over-population of the older towns. The Hitchiti elements consisted principally of the Mikasukis; there were also probably some Yamasis, and certainly some Yuchis and Negroes. The Seminoles are known to history chiefly through their two wars with the United States (see SEMINOLE WAR). On the final surrender the Seminoles (with the exception of some who fled to the swamps), to the number of 3,824, were moved to the West, where they constituted one of the Five Civilized Nations resident in reservations in the Indian Territory; the others were the Cherokees, Choctaws, Chickasaws, and Creeks. The total area of their reservation comprised 365,852 acres, of which 1,932 acres were reserved for town sites, railroad rights of way, and other purposes.

SEMINOLE WAR, the second of the two wars in which the Seminole Indians of Florida engaged against the United States, the first having been a short conflict in 1817–1818, which was ended by Gen. Andrew Jackson (q.v.), who destroyed villages of the Indians and wholly subdued them. The second, which is that usually referred to as the Seminole War, began in 1835 and ended in 1842, and was the fiercest of all wars waged by the United States against Indians. It began in consequence of the refusal of a part of the tribe to make a cession of its lands in Florida and submit to removal to the Indian Territory, in accordance with the terms of a treaty ratified in 1834. On the Indian side the war was at first conducted by the celebrated chief Osceola (q.v.), with whose name it is largely associated; and on the part of the United States it was carried on by Winfield Scott, Zachary Taylor (qq.v.) and other commanders. See SEMINOLE INDIANS.

SEMIPALATINSK, sĕ′mē-pä-lä-tēnsk, Soviet Union, capital of a Region of the same name, Kazak Soviet Socialist Republic, situated on the left bank of the Irtish River in lat. 50° 28′ N., 80° 13′ E. The Region contains rich deposits of gold, copper, lead, and other minerals. The inhabitants, comprising Tatars, Kazaks, and Russians, engage in stock-raising on a considerable scale, and cultivate wheat and other crops. The city of Semipalatinsk is an important commercial center; it is on the route of the railroad between Stalinsk and Alma Ata, and much of its trade is also carried by steamers on the Irtish. Industries include meat packing and the manufacture of leather goods. Pop. (1939) 109,779.

SEMIPALMATED SANDPIPER. See SANDPIPERS.

SEMIRAMIS, sĕ-mĭr′ą-mĭs, a mythical queen of Assyria. According to legend she was a daughter of the fish-goddess Derceto of Ascalon, in Syria, by a Syrian youth. Being exposed by her mother, she was miraculously fed by doves until discovered by the royal shepherds, the chief of whom, Simmas, took her to his own house and brought her up. Her surpassing beauty, according to Ctesias, having attracted the notice of Onnes, the governor of Nineveh, he married her. She subsequently accompanied her husband to the seige of Bactra, where by her advice she assisted the king's operations. Captivated by her abilities as well as by her beauty, Ninus, the founder of Nineveh, asked her of her husband, who refused to yield her, and when Ninus added threats to entreaties hanged himself. As queen of Assyria, Semiramis built Babylon, adding fine buildings and hanging gardens. She led campaigns against Persia, Egypt, Libya, and Ethiopia. Finally with a host of 3,000,000 foot, 500,000 horse and 100,000 war-chariots she engaged in battle with King Stabrobates and was defeated in a battle on the Indus with the loss of one-third of her forces. Upon this, it is said, she vanished in the shape of a dove, or slew herself. Evidently she has no existence in history. She is the goddess of war and of love, the Istar of the Assyrians, to whom the dove was sacred.

SEMIRARA, sä-mē-rä′rä, **ISLANDS,** Republic of the Philippines, a group lying south of Mindoro and the Tablas Strait, between that island and Panay. The group consists of eight islands and a number of small islets, the aggregate area being 60 square miles; the largest island, 35 square miles in area, contains coal of good quality. The people are Visayans, and are mostly engaged in turtle and trepang fishing. Pop. about 600.

SEMITE, a name given to a group of nations allied in language, religion, manners, and physical features, represented in Genesis 10 as descended chiefly from Shem, a son of Noah. The name was used by Johann Gottfried Eichhorn (q.v.), in 1787, in his *Introduction to the Old Testament* (2d ed., i. 15). The habitat of the Semites is Ethiopia, Arabia, Palestine, Phoenicia, Syria, and the countries of the Euphrates and Tigris. Into those lands, according to one theory which is supported by François Lenormant (q.v.) and others, there had preceded them an immigration of Cushites of the Hamitic race, who, proceeding from central Asia, occupied not only the lands that afterward became Semitic, but also the Nile Valley. Their Hamitic language and civilization the Semites are said to have adopted. In language the Semites do show some affinity with the Berbers and the inhabitants of the Nile Valley, and Genesis 10 does, for political and geographical, or other reasons, distribute the sons of Ham and Shem in a peculiar manner. But the increasingly prevalent theory is that not less than 4,000 years B.C. the Semites migrated as nomadic tribes, probably from Arabia into Mesopotamia. There they found a Turanian population dwelling in cities built of brick, under the regular government of priest kings, skilled in the use of metals, using the cuneiform mode of writing, and comparatively far advanced in literature and culture. The hold of the Semites on Shumir, the lower, more fertile, and more thickly inhabited part of the Euphrates Valley, was not at first so strong as on Accad, the upper part. In 3800 B.C. the Semitic adventurer Sharrukin usurped the kingdom of Accad. In Elam also the Turan-

ian population was early overpowered by the intruding Semites, who came to form the upper strata of society. In 2280 B.C. the Semite Khudur-Nankhundi of Elam invaded and conquered Shumar and Accad, founding the Elamite line of princes; and about 2200 B.C. one of his successors, Khudur-Lagamar (Chederlaomer), carried his conquests as far as Palestine (Gen. xiv).

These painful and oppressive impulses, and probably others like them, seem to have occasioned emigrations of many Semites. Some proceeded toward the northwest, reached the Mediterranean Sea, founded Sidon, Tyre and other cities and became known afterward as Canaanites or Phœnicians. Later, from Ur went others in the same direction, settled behind the Phœnicians and were afterward known as Israel. Others went north and built cities which developed into the empire of Assyria. While the Semites were in Mesopotamia they used the Turanian language in their public documents till they attained the ascendant in political power; and when afterward they used their own language they continued to use the Turanian cuneiform mode of writing. The Turanian religion also was adopted by the Semites, and mixed with what religion their own primæval tribal religion or totemism had developed into. This amalgamation was consummated by Sharrukin II of Accad about 2000 B.C.

The Semites as a race have a fine physical organization, are mentally quick, clever but not inclined to change, and not persistent in progress. They have been distinguished by a brilliant imagination and love of the beautiful; but have not shone in philosophy or in science. Their literature has neither epic nor dramatic poetry worth notice. Almost their only arts are the sculpture of Assyria, the exquisite glass and pottery and the textile fabrics and embroidery of the Phœnicians. Impatient of restraint, the Semites have not by political aptitude welded together themselves or others into large, compact and enduring commonwealths. They have made their mark on the world in the Phœnician commerce, which visited even the Atlantic shores of Spain and France and drew tin from Britain; in the Phœnician colonies, which, dotting all the coasts and many islands of the Mediterranean Sea as far as Cadiz, and the coast of Asia as far as India, dispensed manufacture, developed primitive navigation (even to the extent of circumnavigating Africa more than 2,000 years before Vasco da Gama), stimulated industry, trade and ingenuity, and radiated the light of material civilization; in the Carthaginian Empire within Europe and Africa; in the exploits of Hannibal; in the dissemination of alphabetic writing, whereof the Phœnician form was the mother of the European and of most Asiatic alphabets, while the alphabet of the great Sabæan kingdom, or of the great and still more ancient Minæan kingdom in Arabia, is apparently the eldest of all alphabets hitherto discovered; in the Babylonian and Assyrian empires; in the Hebrew Bible and the Jewish religion; in the New Testament and the Christian religion; in the Koran and the Mohammedan religion; in the Mohammedan conquests and empire, and in the preservation of culture thereby during the Dark Ages and the Middle Ages. The difficulty of generalizing with exactitude as to the origin and character of the Semites is increased, as Nöldeke has shown, by the fact that we assume that the most important traits of some Semitic peoples are common to all. In reality some striking features which are ascribed to racial influence are due to external conditions of life, which under similar circumstances are also developed among non-Semitic races. Linguistically, too, it is a no less formidable task to understand aright the kinship of the Semites. They are usually divided into two groups — Northern and Southern. The latter include Arabs, Yemenites, Abyssinians; the rest compose the Northern, whose classification is less happy, as their relationship to each other is less close. As to Semitic origins, it is usually held that Arabia was the Semitic cradle-land, with North Africa that of the Hamito-Semitic race. It is now doubted that they originated in certain districts in Armenia, while the ingenious theory of an eminent Italian Orientalist, Guidi, that the lower Euphrates was their home meets equal disfavor. Consult Brinton, 'Races and Peoples' (New York 1890); Ripley, 'Races of Europe' (1901); Barton, 'Sketch of Semitic Origins' (New York 1902).

SEMITIC LANGUAGES, the languages spoken by the nations of whom Shem was considered the common ancestor. The word Semitic comes from the Septuagint form of the name Shem, Shemitic, derived directly from the Hebrew, being much less frequent. The Semitic languages form a group somewhat like the Aryan group, although the relationship of the different languages is much closer. The members of the group do not entirely correspond to the list of the descendants of Shem given in Gen. x, 21–31; Elam, for example, which is included, in x, 22, was not a Semitic people, while the Canaanites, including the Sidonians, who were Semitic, are given in x, 15 among the descendants of Ham. Such facts indicate that the table of nations in Gen. x was not entirely ethnological, but at least partly geographical: the nations were grouped according to their geographical distribution in the time of the writer.

General Divisions.— The Semitic languages are often divided into two main divisions, Northern and Southern. But the former can be divided into three groups, Eastern, Northern and Middle, which are separated from each other by differences very nearly as great as those between the two divisions first mentioned. It seems better, therefore, to recognize the general division as fourfold, into Eastern, Northern, Middle and Southern Semitic languages.

The Eastern Branch.— The Eastern branch includes the Babylonian and Assyrian languages. Assyrian is really a dialect of Babylonian, there being but very slight phonetic differences between the two, although the difference is somewhat greater in the form of the characters. Babylonian is found much earlier than Assyrian and also continues somewhat later. The Babylonian inscriptions thus far found begin probably about 4000 B.C., possibly somewhat earlier, and extend to the capture of Babylon in 538 B.C. Babylonian was also used later as a literary language under the Persian and Greek rulers of Babylonia. Assyrian inscriptions ex-

tend from about 1800 B.C to shortly before the fall of Nineveh in 606 B.C.

The Northern Branch.— The Northern Semitic or Aramaic branch includes many languages and dialects, to all of which the general term Aramaic is applied. The oldest Aramaic literature is found in the inscription of Zakkūr, 9th to 8th century B.C., and in the inscriptions from Senjirli, of the 8th century B.C., some words on Assyrian and Babylonian tablets being only a little later. The language of these inscriptions differs very much from the later Aramaic languages and resembles the Canaanite language in many particulars. The Aramaic languages are divided into two principal branches, Western and Eastern, the geographical distribution of which was largely in harmony with these names. Western Aramaic may be called one language, with the following principal dialects: Biblical Aramaic, being the language of portions of the Old Testament books of Daniel and Ezra, and of a few words elsewhere in the Old Testament; Targumic Aramaic, usually so-called, the language of the Palestinian Targums; the similar language of most of the Gemara of the Palestinian Talmud and of the Palestinian Midrashim, which is also found in small parts of the Mishna, and also of the Babylonian Gemara; Samaritan, the language of the Samaritan Targum to the Pentateuch; the language of some Jewish inscriptions and papyri from Egypt, dating somewhat before the time of Christ; the language of the few Aramaic words found in the New Testament; the language of the inscriptions found in Tadmor or Palmyra; and the language of the Nabatean inscriptions found in Idumea and vicinity. The only modern representative of Western Aramaic is the language spoken at the present time by a few people near Damascus, in and near the village of Malula, which is written in the Syriac character but belongs in this class. Eastern Aramaic includes Syriac, Mandaic, being the language of the Christian sect of Mandæans who lived east of the Tigris, and the language of the most of the Babylonian Gemara. Syriac was the language of the Christian Arameans and was employed in an extensive literature, chiefly of an ecclesiastical nature, extending from the 2d to the 13th century A.D., including the translation of the Bible known as the Peshitta. The word Syriac means the same as Aramaic and was adopted by the Arameans from the Greeks, because the word Aramaic had come to be used as meaning heathen. After the separation of the two sects known as the Nestorians and Jacobites, each developed its own dialect, known as the Nestorian and the Jacobite, respectively. The actual dialectical differences are but slight, chiefly in the pronunciation of the vowels. In writing, somewhat different forms of the characters were used and the vowels were represented by entirely distinct systems, in the Nestorian dialect by dots, in the Jacobite by characters borrowed from the Greek. The modern representative of the Nestorian branch is the language used by the Nestorian Christians, in parts of Persia, especially in the city of Urmia and vicinity, in some villages in Kurdistan and in portions of Mesopotamia. This language shows very many changes from ancient Syriac, those in the verb being especially striking, while the vocabulary has received very many foreign words, especially from Arabic, Persian and Kurdish. Further, this language shows forms not found in Syriac, but preserved in other Aramaic languages as well as in some of the other Semitic languages, so that it is evidently descended not from ancient Syriac itself, but from a closely related dialect. There are four principal dialects of modern Syriac, that used in Urmia and vicinity, that of northern Persia and some adjacent regions in Turkey, that of Kurdistan and that of Mosul and vicinity. While the language is the same in all these, yet there are very many dialectical variations. The modern representative of the Jacobite Syriac is the language of Tur Abdin, in western Kurdistan, which is similar to the modern Nestorian language, but with many differences.

The chief general feature that distinguishes the Eastern and Western Aramaic languages is the preformative of the imperfect. This is *y* in all the Western Aramaic dialects, although a few forms with *l* are found in Biblical Aramaic, and *n* in all the Eastern, although Mandaic and the Babylonian Talmud have *l* along with *n*. In modern Syriac the verbal form is so much different that no preformative is used.

The Middle Branch.— The middle Semitic branch is also called Canaanite, for all its languages are often included under the general term Canaanite. The only one of these languages in which much literature has survived is the Hebrew. Nearly all of the Old Testament is in ancient Hebrew. Aside from this, the oldest Hebrew documents are probably about 75 inscribed potsherds found at Samaria in 1910, written in ink by a reed pen, containing brief business memoranda. These are usually ascribed to the time of Ahab, the first half of the 9th century B.C. A small limestone calendar tablet was found at Gezer in 1908 and is assigned to the 8th century. The Siloam inscription is usually dated at about 700, but is possibly much later. Various inscribed Hebrew seals have been found, dating perhaps from the 8th century on. Coins with Hebrew characters are from the 2d century B.C. to the 2d century A.D. New Hebrew or Mishnaic Hebrew is found chiefly in the Mishna, and also somewhat in the Gemara and in related works. Hebrew has continued to be used somewhat by the Jews as a literary language even to the present time, most of the later literature being produced in the Middle Ages. The language as thus used is ordinarily similar to Mishnaic Hebrew. The Phœnician has much that is identical with the Hebrew, while the differences are slight, affecting the vowels more than the consonants, although the vocabulary shows some variations. It is found in inscriptions from Phœnicia and her colonies, prominent among the latter being Carthage, where the language was called Punic. Considerable portions are also found quoted in works of Latin and Greek authors, chiefly in the Pœnulus of Plautus. Most of the Phœnician inscriptions are from the 4th century B.C. and later, some are as old as the 6th century, while the oldest inscription may belong to the 8th century or a little earlier. The inscription of Eshmunazar, from the time of Alexander the Great, is the most important. In this group are also included the Canaanite, Moabite, Ammonite and Edomite languages. The last two are known only from the proper names found in the Old Testament and the inscriptions of other nations,

the Moabite from that source and also from the Moabite stone, written by Mesha, king of Moab, and dating from about 850 B.C. The Canaanite, aside from information given in the Old Testament, is known from glosses found in the Tell el-Amarna tablets (see AMARNA LETTERS) about 1400 B.C. All four are substantially identical with Hebrew, the Canaanite and Moabite, which of course are known more fully than the other two, showing slight dialectical variations. Moabite and Phœnician, like Hebrew, have *waw* consecutive with the imperfect. Some of the Philistine proper names given in the Old Testament are Semitic. It is generally agreed, however, that the nation was not Semitic, but perhaps learned and used the common Canaanite language after their arrival in Palestine.

The Southern Branch.— The Southern Semitic branch is sometimes called the Arabic group, because the Arabic language is its most important representative. Under Arabic may be included ancient or classical Arabic, its descendant, modern Arabic, and southern Arabic, often improperly called Himyaritic, including the closely related dialects of Sabæan and Minæan. The great work in ancient Arabic is the Quran, composed by Mohammed (570–632 A.D.), although a few poems are older than this. Printed modern Arabic is substantially the same wherever found and does not differ greatly from the ancient language. The spoken language, however, is divided into many dialects, of which the most important are those of Syria, Egypt, Mesopotamia, Tunis, Malta and Oman and Zanzibar. Under the general head of modern Arabic may be included the very extensive Arabic literature from soon after the time of Mohammed down to the present time. Sabæan and Minæan are found in inscriptions, chiefly in southern Arabia. These are of uncertain date, although it is now often claimed that the earliest Minæan inscriptions are earlier than 1000 B.C., while the oldest Sabæan are somewhat later. Modern representatives of these dialects are found in the present dialects of the same region, of which little is known, two of them being the Mahrī and the Socotrī. Included in the Southern Semitic branch is also Ethiopic, or more properly Geez. This was probably a descendant of Sabæan. The ancient Ethiopic was the language of Abyssinia. It closely resembles the Arabic dialects, sharing with them some of their most characteristic features, while in many other respects it differs greatly from them. It was the spoken language of Abyssinia till about the 13th century A.D. The earliest known literature comes from about 500 A.D. Most of the literature consists of translations from other languages. The most important documents are the translation of a part of the Bible, made about 500 A.D., and the apocryphal book of Enoch, which is a translation from a lost original. Modern representatives of the language in the same region are the Tigré, the Tigrina and, with extensive incorporation of foreign elements, the Amharic, together with dialects related to the Amharic, such as the Hararī and Gurāguē.

The Egyptian language is by some classed as Semitic. It seems evident, however, that that is not the case, but that very early, in prehistoric times, it was subjected to strong Semitic influences, doubtless from invaders coming from Asia.

The Written Characters.— The written character of the Babylonian and Assyrian languages is the cuneiform, the writing being partly ideographic and partly syllabic, but not at all alphabetic. (See CUNEIFORM WRITING). This, however, according to the common view, was not the invention of the Babylonians, but was taken by them from the earlier inhabitants of the land, the non-Semitic Sumerians. It was originally a picture writing, like the hieroglyphics of the Egyptians, but has been so largely conventionalized that in most cases the resemblance to the original picture has been lost. The Assyrian forms, when they differ from the Babylonian, show modifications in the direction of greater conventionalizing and increased regularity. Aside from the cuneiform, all Semitic languages use an alphabet, consisting entirely of consonants, which goes back to the same original forms. Ethiopic is an apparent exception, in that the vowels are written with the consonants, that is, each consonant has six or more different forms according to the vowel following it. These forms have such a resemblance to those of the other Semitic languages, however, and in particular to the Sabæan which is written without vowels, that it is probable that the earliest form contained simply the consonants, and that the modifications of form for the expression of the vowels show a later development. What is commonly regarded as the earliest form of the Semitic alphabet is usually called the Phœnician, a name given to it by the Greeks because they obtained it from the Phœnicians. But the Phœnician alphabet at the time of our earliest knowledge, about the 8th century B.C., was practically identical with the forms found at about the same time among the other Canaanites and the Aramæans. The origin of this alphabet is doubtful, the common view at the present time being that it was derived from certain Egyptian characters, while some regard it as taken from the Babylonian. After the Greeks obtained this alphabet, it passed from them to the Romans and then to the many modern alphabets derived from the Greek and Latin. The earliest inscriptions known in this alphabet are probably the ostraka from Samaria in Hebrew, of the 9th century, the Hebrew Gezer inscription, of the 8th century, the Moabite stone, about 850 B.C., in the Moabite language, a Phœnician inscription of about the same date, the Siloam inscription, about 700 B.C., in Hebrew, the Zakkūr inscription and the inscriptions from Senjirli, about the 8th century B.C., in Aramaic. All these have substantially the same forms. Within the next few centuries two types gradually arose, the old Hebrew and the Aramaic or square characters. The old Hebrew was used in writing Hebrew till the Jews adopted Aramaic as their vernacular, which was at any rate before the time of Christ, when they naturally came to use ordinarily the Aramaic form of character for the Hebrew as well. The Samaritans have always used the old Hebrew form of character, with many changes, especially in the direction of greater elaborateness. The only modern use of this form of character is in the Samaritan of the present day.

The earliest Syriac character, known as the Estrangela, was a cursive writing developed

from the Aramaic form. From this came the later Syriac forms, both Nestorian and Jacobite, and also the Arabic characters, including both the Kufic and the Neskhi.

The southern Arabic characters, found in Sabæan and Minæan, differ greatly from those already mentioned, and are perhaps earlier than any other forms which have been found. They are to be traced, however, to the same common character in an early form. The Ethiopic character is a development of the southern Arabic form.

The Ethiopic language and the Assyrian and Babylonian are written from left to right. All the other Semitic languages are written from right to left.

General Characteristics of the Semitic Languages.— The modern Semitic languages and dialects have of course been greatly changed by the influence of the other languages with which they have been brought in contact. These, therefore, should not receive a prominent place in the consideration of the general characteristics of the Semitic languages, although they may offer confirmatory testimony in some particulars. Some of these general characteristics of the ancient Semitic languages may well be noted, keeping in mind a comparison with other languages, especially with the Aryan group. It is not claimed, of course, that the characteristics which will be here named have no similarities elsewhere, but rather that they may fairly be considered general characteristics of the Semitic group, as they could not be of any other group.

The Semitic languages divide the letters into two general classes, consonants and vowels, the consonants being the more important. Roots are composed only of consonants, while the vowels are used, along with consonantal changes, to express modifications of the fundamental root idea. Although the vowels are thus important, it is in a domain entirely subordinate to the consonants. The result of this is that in all the languages except the Assyro-Babylonian and Ethiopic the consonants only were originally written, and the vowels added by means of small marks, for the most part above or below the consonants. In fact, it was only in comparatively late times that the vowels were written at all. The inscriptions, such as those of Phœnicia and of Senjirli, the Moabite stone and the Siloam inscription, have no vowels. In the Assyro-Babylonian the vowels are expressed, but the characters are usually supposed to have been borrowed, as has already been noted. In the Ethiopic the vowels are expressed by slight changes in the form of the consonant, a feature, however, which is probably to be regarded as a late development, although going back to the earliest known literature. The consonants alone were probably originally written.

Originally the Semitic languages were characterized by the possession of a large number of gutturals, some of them very peculiar. In course of time, however, part of these were lost by most of the languages, the Arabic preserving them the most fully.

The Semitic roots are almost entirely triliteral, that is, each consists of three consonants. An occasional root is found which contains four or more consonants, but these are exceptional. On the other hand, the belief is growing that many of the triliteral roots, especially some of the so-called weak roots, were originally biliteral. But here the tendency of the languages toward triliterality is seen plainly from the fact that to a large extent these roots have assumed the appearance of triliterality.

The relation between nouns and verbs is very close. In fact most of the features of inflection are the same in both, the noun being the earlier.

A prominent characteristic of verbal inflection, with many similarities in the nouns as well, is the development of many different stems or conjugations from the same root. These are formed partly by internal change in consonants and vowels and internal additions and partly by external additions. Thus one stem has an intensive meaning, another a causative, another a reflex, etc. In the original Semitic there must have been many different stems. Some have been lost in each language. The Ethiopic has preserved the largest number, next the Arabic, then the Assyrian. These stems afford a very concise way of expressing many different shades of meaning connected with a single root idea, each of which would in most languages require either a compound verb or the addition of separate words for its expression.

The languages use pronominal suffixes attached to nouns, verbs and prepositions. These are really shortened forms of the pronouns. With nouns they have the force of a genitive, with prepositions of a dative and with verbs ordinarily of an objective accusative.

The languages are distinctly objective. The personal standpoint of the speaker or writer counts for little. In the verb, the third person is the simple uninflected form, the starting point of the inflection, it is the first person in the Aryan languages. The present time, the time of the speaker or writer, is of little importance in comparison with the past and future. The use of the tenses is often based upon an assumed standpoint. So also many phases imply the assumption of a standpoint other than that of the writer or speaker.

Certain phenomena may be classed together under the general statement that they show a lack of development in the languages. This is not, however, due to lack of time or of favoring circumstances, because these features are ordinarily found to characterize in a similar way all the languages at all times and under all circumstances. These phenomena indicate rather psychological characteristics of the people, their natures are not complex, they show limitations in some directions. Certain developments which are common in Aryan languages the Semites did not feel to be necessary. Among these characteristics may be mentioned the following:

Most of the Semitic languages have only two tenses, usually called the perfect and the imperfect. Whether these differed in their fundamental meaning from some of the tenses of the Aryan languages is a question on which there is difference of opinion. The later forms of several of the languages developed a present tense from a participle, which is only suggested in the earlier usage. In general the Semitic tense usage is thus much less fully developed than the Aryan. Moods also are relatively undeveloped. They are found only in connection with the imperfect tense, even the impera-

tive being derived from it, and in most of the languages they are not widely used.

The nouns have only two genders, masculine and feminine.

There is an almost entire absence of compound words, both nouns and verbs, except in proper names.

The syntax is in many particulars of a simple and undeveloped kind. There is a strong tendency to leave much in the relation of clauses and sentences to inference. This leads to the very frequent use of parataxis. There is but a small number of particles of every kind. In most of the languages the original case endings have been lost, but there has been no great development of prepositions to take their place. There is also a scarcity of adjectives in most of the languages, so that nouns are often used in their stead.

Relation to the Primitive Language.— No existing language can be called the common mother of the other Semitic languages, nor even the most primitive in every respect. Each of the languages is probably in some features more primitive than any other. But the Arabic preserves far more that is primitive both in grammatical forms and syntactical usage than any other of the languages. This is in spite of the fact that the known Arabic literature is very late. The Arabs in their desert home remote from other nations changed the language less than other peoples in a short space of time. Thus the Arabic preserves the case endings, which have been largely lost in the other Semitic languages, except in the Assyro-Babylonian where they are often used indiscriminately. The Arabic preserves the original endings, sometimes consonants, more often vowels, both in verbs and nouns, which are largely lost elsewhere. The Arabic retains in most cases the original vowels, which in the other languages undergo various changes, such as heightening, shortening (volatilization) and contraction, although the Ethiopic has also retained many of these. The formation of the plural nouns by internal changes, the broken plurals, which is so prominent a feature of the Arabic, is only found elsewhere in Ethiopic. This was probably a primitive feature.

GEORGE RICKER BERRY,
Professor Emeritus of Old Testament Interpretation and Semitic Languages, Colgate Univ.

SEMITIC NATIONS, those nations whose languages were Semitic, and which are consequently supposed to have been racially connected. It is recognized, of course, that language is not an infallible evidence of race, and that the conclusions on that point drawn from it have at least a small degree of uncertainty. But in the absence of much evidence of any other kind, the data supplied from this source must be used as a working basis. (See SEMITIC LANGUAGES). In considering the Semitic nations as a group, the first question is, of course, concerning their primitive home. Primitive is here used only in a relative sense, for the very earliest history of these nations goes back to a time concerning which, in the present state of knowledge, there is no positive information or plausible inference. The consideration of that time would involve a discussion of the origin of the whole human race, which is a question too broad to be entered upon here. By primitive home is meant, therefore, the location of the Semites when they were one people, the common distributing point of the Semitic nations. While entire certainty on this point is not attainable, yet there are some indications which may be followed.

Some have found this primitive home in Babylonia or its vicinity. For this the chief argument is based upon language. A consideration of the words common to all the Semitic languages is thought to point to the conditions prevailing in Babylonia, or in some adjacent country from which Babylonia was the first stopping place of the undivided race. But this argument from language is inconclusive, in view of the possibility of the disappearance from a language of words once common, and also of the borrowing by one Semitic language from another. The fact that the known history of Babylonia extends back to a point much earlier than that of any other Semitic nation has very little to do with the question.

There are many arguments in favor of Arabia, that is, central and northern Arabia, as the primitive home. Arabia is a country which is largely desert, except in the southern part. Such a country, it is said, best explains the racial characteristics. These characteristics, as usually given, are intensity of faith, ferocity, exclusiveness and imagination. It is also said that the Arabs have preserved the Semitic character and characteristics in their purest form. Certainly those characteristics which have just been mentioned are found combined among the Arabs more fully than elsewhere. A desert origin seems, also, to explain most satisfactorily some features of the Semitic languages. This is true especially of the great predominance of gutturals. Such a development of these as was found in primitive Semitic demands good physical powers, which would come from an outdoor life in a pure atmosphere, and plenty of leisure for conversation. These conditions are met in Arabia. In this connection it is important to note that the Arabs have preserved the gutterals more fully than any other Semitic nation, the others having considerably modified their primitive habits of life. Again, it is by some regarded as a universal law that nomads may adopt settled habits of life, but that the reverse process does not take place. This rule perhaps is not invariable, yet it does represent the usual tendency. When,

therefore, we find some Semitic nations nomadic and others not, it follows that the nomadic form of life is probably the earlier. For this nomadic form of life the natural location is Arabia. Further, the close resemblance of the Semitic languages to one another, much closer than in any other known group of languages, indicates some of the early conditions surrounding the nation. It suggests that the primitive nation lived in a comparatively limited space for a long period of time before being divided, giving opportunity for much common development of the language and also that it was largely isolated from other nations who would influence the language. Such a country of moderate size, in comparative isolation from other countries, is Arabia alone in the region inhabited by Semitic peoples, or in their vicinity.

Another view is that the primitive home was in Africa. According to this view, however, as ordinarily held, the Semites very early migrated into Arabia and there lived for a long period of time before any division took place. This view would, therefore, make Arabia the centre of distribution for the Semitic nations. Hence the arguments already adduced in favor of Arabia would still be valid upon this view, but additional arguments are presented in favor of going back one step further to an African home. In support of this view the chief argument is that there is supposed to be a racial connection between the Semitic and Hamitic peoples. By Hamitic peoples are not meant the negroes, but the Egyptians, Berbers, etc., although it is by no means certain that the Egyptians are Hamitic. For this racial connection there are two chief arguments. One is from resemblance in physical characteristics, concerning which, however, the evidence is inconclusive. The other is from resemblance of the languages and is of greater force. The general resemblance between the Hamitic and Semitic groups of languages are the following: the pronouns are similar; the verbs have similar tenses and formation of stems; it is claimed by some that the Hamitic roots, like the Semitic, were originaliy triliteral; the ending for feminine gender is the same, *t;* several of the numerals are very similar; both groups form nouns by means of a prefixed *m;* both write without expressing the vowels; and 50 or more words of ancient Egyptian are said to be identical with Semitic words. The possibility of accounting for these resemblances by borrowing from the Semitic languages by the Hamitic does not seem, however, to be entirely excluded. Of course, not all of the resemblances are such as are most liable to be borrowed, but any of them might be. The possibility of such borrowing is increased, too, by other considerations. For the Egyptian resembles the Semitic languages more than any other Hamitic language. And it has been thought, on other grounds, that Egypt has been subject to Semitic influences in early times. Some have believed, for example, that certain features in early Egyptian civilization were taken from the Babylonians. Others have thought that Arab invaders came into Egypt in early times. Such a relationship as is claimed between the Semitic and Hamitic races can not be said, therefore, to be yet established. And even if there were such a relationship, no sufficient reason appears for thinking that the primitive race must have had its home in Africa rather than in Arabia.

The conclusion that the earliest known home of the Semites was in Arabia may be said, therefore, to be reasonably well established. The arguments which are thought to show a previous residence in Africa are inconclusive. That view can only be regarded, in the present state of knowledge, as a conjecture with very little evidence to support it.

Separation into Nations.— Concerning the precise, or even approximate, date of the separation of each nation from the parent stock nothing is known. The recorded history of every Semitic nation begins long after that time. Even the order of departure of the different nations is not certain. Here, however, the languages themselves come in to supplement our direct knowledge. On account of the resemblances of the languages to each other, the order of separation is often stated thus. All the other groups departed from the southern, that is, migrated from Arabia, and settled in Babylonia and its vicinity. After dwelling here together for a long time, the Arameans first separated, then the Canaanites, and finally the Assyrians. There was also emigration southward, giving the southern Arabs, a branch of whom ultimately migrated to Abyssinia. It is doubtful, however, whether this outline is correct in all details. It assumes that the Canaanites are more closely related to the Babylonians than are the Arameans, while in reference to some features of the languages the reverse is true. It also presents difficulties in accounting for the Arameans from the time of such separation until their appearance in history. For while some had settled in upper Mesopotamia at an early time, yet the Assyrian inscriptions indicate that fresh streams of migration were coming into upper Mesopotamia, and into Babylonia and Assyria, for a considerable period of time before and after 1000 B.C., apparently from Arabia. It seems probable then, that at the first general separation between north and south, the ancestors of the northern nations went not to Babylonia, but to northern Arabia. After a considerable sojourn there, the Babylonians continued their journey to Babylonia, and part or all of the Canaanites, after a time, went on to Canaan, while the Arameans remained in northern Arabia, from which region successive waves of migration swept over Mesopotamia, Syria and their vicinity. The nomadic habit of life of many of the Arameans, which seems to be indicated in the Assyrian accounts, also points to such a residence in Arabia as is here indicated. Contact after the original division doubtless had much influence on language. The Arameans were probably thus influenced by the Arabs and by the Babylonians. The Babylonians themselves were also influenced by the Arabs with whom they had commercial intercourse in early times. Further, the Canaanites were without doubt influenced by the early intercourse between Babylonia and the region of Palestine.

The Individual Nations.— The earliest Semitic nation of which we have any history was in Babylonian. Their own records, which begin perhaps about 3000 B.C., give the first information concerning them. The earliest inscriptions show them already in Babylonia, but there are indications, as usually understood. of early con-

flicts with the original Sumerian inhabitants in southern Babylonia. Ultimately, however, the Sumerians became subject to the Babylonians and were gradually incorporated by them. In course of time the people of Babylonia became a mixture of various elements, Semitic and non-Semitic. The non-Semitic Elamites and Kassites had dominion over the land at various times, and must have contributed materially to the population. In the course of their history also it is probable that many Arabs and Arameans were incorporated into the population. The Babylonians remained a distinct people until their conquest by the Persians under Cyrus in 538 B.C., after which time they never again became independent, and doubtless were mingled with the Persians and others with whom they associated. The Babylonians were never nomads in historical times, but dwelt largely in cities. In all early history and to about 2000 B.C., the government was one of cities, with no power actually supreme. The Babylonians were not unwarlike, but were especially devoted to religion, commerce, science and education. Assyria was doubtless settled by colonists from Babylonia somewhat before 2000 B.C., and was at first subject to Babylonia. From about 1500 B.C., however, the nation was independent, and for most of the period from 745–606 B.C. held Babylonia in subjection, as well as at times before 745. Their national history ended with the capture of Nineveh by the Medes in 606 B.C. The Assyrians were much more warlike than the Babylonians, and considerably given to commerce, but cared much less than the Babylonians for religion, science and education.

The Arameans were not one nation, but rather many tribes. They came in waves of migration from Arabia to the frontier of Babylonia, and to upper Mesopotamia and finally reached the country later called Syria. In the Old Testament, Arameans are alluded to in connection with Abraham and his descendants, especially Jacob. The earliest mention of the Arameans elsewhere is probably in the Tell el-Amarna letters in the early part of the 14th century B.C. The Assyrian kings also speak of them from time to time in their inscriptions, beginning in the 14th century. From all indications it would seem that their earliest settlement of importance was in the upper Mesopotamia, between the rivers Euphrates and Khabur. This settlement was reinforced by fresh arrivals from time to time. Just when they passed over the Euphrates and occupied Syria is uncertain, but the indications suggest that somewhat before 1000 B.C. they had obtained possession of most of the country, especially the northern and middle portions, defeating and driving northward the Hittities who had previously possessed the country. About the same time they began to come in large numbers into the territory of Assyria and Babylonia, especially along the Euphrates. In the times of Tiglathpileser III and later, 745 B.C. and afterward, they also had settlements along the lower Tigris. In the earliest notices of them they were largely nomadic, but they soon turned to settled habits of life. In their government there was little unity; each political division consisted of a strong city and the people inhabiting a greater or less amount of territory around the city. Several of these city states would unite for a campaign, but these leagues never lasted long. The Old Testament speaks of the Arameans in connection with several cities, namely, Damascus, Zobah, Maakah and Beth Rehob. Other prominent cities of the Arameans were Hamath in Syria and Haran in Mesopotamia. Upper Mesopotamia is spoken of in the Old Testament as a region by the names Aram Naharayim and Paddan Aram. The most powerful of the Arameans were included in the kingdom of Damascus, but their power was broken when Damascus was captured by Tiglathpileser IV about 732 B.C. After this time the population of Syria and upper Mesopotamia no doubt continued to be largely Aramean for centuries, although the people did not form a nation, and had little political power. Of the many who used the various Aramean languages and dialects after this time (see SEMITIC LANGUAGES), it is probable that a large part were Arameans. But naturally many others were mingled with them, so that in their latter history the Aramaic-speaking people represented a mixture. The language was also adopted by those who were not Arameans, as, for example, by the Jews. Some who have left inscriptions in the language were not Arameans, but Jews and Arabs. The Arameans were a people of considerable warlike ability, although with little taste for political organization, and were much given to commercial pursuits.

All the Canaanite Semitic nations aside from the Hebrews, namely, Canaan, Ammon, Edom, Moab and Phœnicia, were occupying their respective countries before the arrival of the Hebrews from Egypt, how long before is not known with certainty. The Phœnicians are mentioned in Egyptian records as early as the 16th century and are prominent in the Tell el-Amarna letters. The Phœnicians were distinguished beyond any other Semitic nation as a commercial people, especially on the sea, and were great colonizers. Their form of government was the city state, Tyre and Sidon being the two most prominent cities. Whether the Hebrews were actually Canaanites or were a branch of the Arameans is uncertain, the indications for the latter view coming entirely from the Old Testament. If this view be correct, the Hebrews spoke Aramaic on their arrival in Canaan, and learned the Canaanite language from the people there. The other view is, however, rather more probable, according to which the Hebrews were themselves a branch of the Canaanites, although traditionally associated with the Arameans in the experience of Abraham, the founder of the nation, and his immediate descendants. The earliest statements concerning Abraham in the Old Testament connect him with the city Ur in Babylonia. Both the Old and New Testaments originated among the Hebrews. The Hebrews were not particularly distinguished as warriors, and in ancient times had no inclination toward commercial pursuits.

If the earlier conclusions concerning Arabia as the distributing point of the Semites are true it is evident that after the departure of the nations hitherto mentioned the Arabs remained by themselves in central and northern Arabia at a period long before we have any record of

them. There are no indications in the early history that the Arabs had a centralized government. Rather it would seem that, being nomadic, they were early separated into many different tribes, having no political unity. They are mentioned quite often by the Assyrian kings who fought against them, beginning with Shalmaneser III in 854 B.C. Their chief military activity came during and after the time of Mohammed.

Of the time of migration into southern Arabia there is no definite information. Southern Arabia is of a different character from the rest of the land, being fertile and adapted to agriculture. The immigrants here naturally abandoned the nomadic habit of life. The knowledge of these south Arabian kingdoms comes chiefly from their own inscriptions, whose date is by no means certain. It is now thought, however, by those who have given special attention to the matter that the earliest south Arabian kingdom was the Minæan, extending from about 1250–600 B.C., at the latter date being conquered by the Sabæans, while the Sabæan kingdom lasted from about 750–100 B.C. Both were evidently kingdoms of considerable power. Probably about 350 A.D. some Sabæans migrated to Abyssinia, and there founded the kingdom of Aksum, where the language called Ethiopic was spoken.

Characteristics of the Semitic Peoples.—It is evident that the Semites as a whole were decidedly religious. But it is now evident that there was no Semitic tendency to monotheism, as was formerly supposed. The three great monotheistic religions of the world, to be sure, Judaism, Christianity and Mohammedanism, have come from the Semites. But Mohammedanism was strongly influenced by Judaism, and Judaism and Christianity owe more of this teaching to the work of great individuals than to any natural tendency of the Hebrews. The Hebrews had, in fact, a tendency to polytheism, as is shown by their history in the Old Testament. The Arabs were polytheists before the time of Mohammed. All the other Semitic nations, so far as we know, were polytheistic.

In considering other characteristics and achievements of the Semites, especially in comparison with the Aryans, it needs to be remembered that the prominence of the Semitic nations precedes that of the Aryans. Hence the Aryans have been able to profit by whatever was good in the Semitic achievements. Considered in the light of their own times, the Semites were not deficient in those traits which have distinguished the Aryans. Usually, however, not more than two or three Semitic nations have manifested conspicuously any one of such traits. In warfare the Arabs, under Mohammed and his successors, the Assyrians and the Babylonians achieved signal success. The Assyrians, for their own time, were great organizers of conquered territory. The scientific attainments of the Babylonians were such that nearly all nations of antiquity learned many things from them, such as astronomy and mathematics. The Assyrians and Babylonians showed much artistic ability. Much of the literature of the Semitic nations is imaginative, especially the poetry and mythology.

GEORGE RICKER BERRY,
Professor Emeritus of Old Testament Interpretation and Semitic Languages, Colgate Univ.

SEMLIN, ZEMUN, a city of Jugoslavia, at the junction of the Danube and Save rivers, opposite, and four miles from Belgrade. It has a large transit trade, and is the seat of an Orthodox bishop. In 1914 the city was evacuated and reoccupied twice by the Austrians. It suffered greatly from repeated bombardment. Pop. about 25,000.

SEMLIN, Charles Augustus, Canadian statesman: b. Ontario, 1836; d. 1917. He went to British Columbia in 1862, spent some years in the Cariboo district and settled at Cache Creek. He was largely interested in agriculture and in the meat industry. He served many years in the assembly of British Columbia and was Premier in 1898–1900. He was afterward Commissioner of Lands and Works, Provincial Secretary and Minister of Education.

SEMMERING, zĕm'ĕr-ĭng, Austria, an Alpine pass on the borders of Styria and Lower Austria, 44 miles southwest by west of Vienna. The road over the Semmering Pass (2,940 feet) is of ancient date and here between 1848 and 1853 was built the famous Semmering Railway, the first of the European mountain railways. The railway begins at Gloggnitz and is carried along the face of precipices by means of 15 tunnels and 16 viaducts to Mürzzuschlag. The scenery along this portion of the line is of the grandest and most picturesque description. At its highest elevation, 2,891 feet, the line pierces the Semmering in a tunnel 4,667 feet long. Its entire length is 25 miles and it was constructed for the Austrian government at a cost of about $7,000,000.

SEMMES, sĕmz, **Raphael,** American naval officer: b. Charles County, Md., 27 Sept. 1809; d. Mobile, Ala., 30 Aug. 1877. He became a midshipman in the United States navy in 1826, a lieutenant in 1837, was volunteer aide to General Worth in the Mexican War and secretary to the lighthouse board in 1859–61. Upon the secession of Alabama he resigned his commission and was assigned to the command of the steamer *Sumter,* the first vessel of the Confederate navy. With this ship he cruised with success against Northern commerce in the West Indies. He then had the swift steamer *Alabama,* or No. 290, built in England, and in September 1862 started on his well-known voyage. He flew British colors when approaching his prey, hoisting the Confederate ensign when sure of his prize. His seamen were chiefly English. After a destructive career, during which he captured 64 vessels and burned all but seven, his ship was sunk off Cherbourg Harbor, France, by the Federal steamer *Kearsarge.* Subsequent to the war he practised law. His writings include 'Afloat and Ashore During

the Mexican War' (1851); 'The Cruise of the Alabama' (1864); 'Campaign of General Scott in the Valley of Mexico' (1852); 'Memoirs of Service Afloat During the War Between States' (1869).

SEMNOPITHECUS, a genus of Asiatic monkeys, the langurs, including species possessing an elongated tail, cheek pouches and ischial callosities. All of this genus are inhabitants of Asia and Asiatic islands. The sacred entellus monkey is a familiar example. See LANGUR.

SEMOLINA, hard grains of wheat left in the bolting cloth when the fine flour has been passed through its meshes and some times manufactured by millers. Certain hard, large-grained wheats growing in southern Europe produce the best semolina, which is used for thickening soups, for macaroni, for a French bread, as an addition to the Italian polenta and is employed in puddings, especially in England.

SEMPACH, zĕm'päH, Switzerland, in the canton of Luzerne, lies eight miles northwest of the town of Luzerne, on the lake of the same name. It is a walled town and its chief interest consists in its having been one of the outposts of the Swiss in their conflict with Austria. The battle of 9 July 1386, in which the Austrians under Duke Leopold received a crushing defeat at the hands of the confederated Swiss, was fought under its walls — a victory the more remarkable as won against extraordinary odds, and in which the famous Winkelried was the hero; the duke with 600 knights were left upon the battlefield. The anniversary of this victory is always celebrated on this spot by prayers and thanksgiving. Pop. 1,200.

SEMPER, zĕm'pĕr, **Gottfried,** German architect: b. Hamburg, 29 Nov. 1803; d. Rome, 15 May 1879. He attended the Johanneum of his native town and studied law in the University of Göttingen, but changed to the profession of art, having been attracted to the study of architecture under Gau. He then took a journey through Italy, Sicily and Greece. On his return he published 'Bemerkungen über bemalte Architektur und Plastik bei Alten' (1834), and the essays 'Die Anwendung der Farben in der Architektur und Plastik' and 'Dorisch-Griechische Kunst in 6 Tafeln mit Farben' (1836). He became the pupil of Schinkel in Berlin, who ungrudgingly recognized his talent and educated him to fill the place of professor of architecture in the Dresden School of Building. Between 1837–41 he built several important structures in Dresden, including the Court Theatre, and in 1849 traveled to Paris and London, in which latter city he undertook, among other things, the arrangement of the statuary in Kensington Museum. He was active up to the time of his death in Dresden, Vienna and other places, where his work is still a commanding feature of city architecture. He was an uncompromising adherent of the Renaissance style, as far as this was founded on the Roman of the later empire, especially as exhibited in the composition of the forums. His buildings are distinguished for harmony of composition together with purity and moderation of detail. Among his many works on architecture may be noted 'Uber Poly chromie und ihren Ursprung' (1851); 'Wissenschaft, Industrie, und Kunst' (1852), and 'Der Stil in den technischen und techtonischen Künsten' (1860–63). Consult Lipsius, 'Gottfried Semper in seiner Bedeutung als Architekt' (1880).

SEMPER, Karl, German naturalist: b. Altona, Germany, 6 July 1832; d. Würzburg, Bavaria, 29 May 1893. He was educated at Kiel, Hanover and Würzburg, traveled extensively in Europe and was engaged in a tour of the Philippines, China, Japan and the South Sea Islands in 1858–66. On his return he was appointed to the chair of zoology at Würzburg which he occupied until his death. He delivered a course of lectures before Lowell Institute of Boston in 1877, afterward published under the title 'Animal Life as Affected by the Natural Conditions of Existence' (1881). He edited nine volumes of 'Arbeiten aus dem Zoologischen Institut' in Würzburg, and also wrote 'Reisen im Archipel der Philippinen' (1867–72); 'Die Palau Inseln im stillen Ozean' (1873); 'Die natürlichen Existenzbedingung der Thiere' (1880), etc.

SEMPILL, Robert, Scottish ballad writer: b. about 1530; d. 1595. He was probably a cadet of the house of Sempill, of illegitimate birth; received an excellent education; spent part of his early life in Paris, and upon his return to Scotland went into military service. He ardently supported the Reformation in Scotland in his writings and severely attacked the Catholic cause. The majority of his poems have been preserved in the original, the most noteworthy of them being 'Ane Complaint upon Fortoun' (1581); 'The Legend of the Bischop of Saint Androi's Lyfe' (1584), and the 'Sege of the Castel of Edinburgh.' Two complete editions of his writings were published, 'The Sempill Ballates,' edited by T. G. Stevenson (Edinburgh 1872), and 'Satirical Poems of the Time of the Reformation' (edited for the Scottish Text Society by James Cranstoun, 2 vols., Edinburgh 1889–93). The last two poems were included in the 'Scottish Poems of the Sixteenth Century' (edited by Sir John Graham Dolyel, 2 vols., Edinburgh 1801).

SEMPLE, Ellen Churchill, American anthropogeographer: b. Louisville, Ky., 1863. She was graduated at Vassar College in 1882 and in 1891–92 and 1895 studied at Leipzig. She has specialized in the study of the effect of geography on the development of races and on national life. She was professor of anthropogeography at Clark University from 1921 to 1928. She was a contributor to the *Bulletin* of the American Geographical Society and the *Geographical Journal* (London). Gold medalist, 1914, American Geographical Society. Author of 'American History and Its Geographic Conditions'; 'Influence of Geographic Environment' (1911). She died 8 May 1932.

SEMPRINGHAM, Order of. See ORDERS, RELIGIOUS.

SEN, Keshub Chunder, an Indian religious reformer: b. village of Garifa (Gouripore), Bengal, 19 Nov. 1838; d. 8 Jan. 1884. His education was partly Hindu and partly English. He became attracted in 1858 to the Brahmo-Somaj, the Theistic Church of India, so much so that he soon began a campaign of religious reform for the regeneration of his fellow-countrymen. In 1865 a split in this Church oc-

curred, and one part known as the Brahma Samaj of India, came under the vigorous leadership of Sen. Until his death in 1884 Sen extended the movement's influence throughout India, initiated social reforms, and sought to develop a Christian-like personal religion among his followers. Quality rather than quantity characterized the movement. But while the intellectuals among its adherents, particularly in Calcutta, abandoned traditional Hindu observances, they adopted nothing in their place except positivism or agnosticism. In 1878 dissensions arose among Sen's followers and his congregation split. The last few years of his life were full of controversy, illness, and disappointment.

SENANCOUR, sā-näN'kōōr, **Étienne Pivert de,** French writer: b. Paris, France, Nov. 16, 1770; d. Saint Cloud, Jan. 10, 1846. Destined by his father for the priesthood, he went to Switzerland in 1789 to avoid attending a seminary. His marriage to a young Frenchwoman at Fribourg the following year was not happy. During the French Revolution he was included in the list of emigrants, and most of his fortune in France was lost. He returned to France permanently in 1803. Sénancour was a great admirer of Jean Jacques Rousseau, who inspired much of his *Rêveries sur la nature primitive de l'homme* published at Paris in 1799, and his best-known work, *Obermann,* an autobiographical epistolary novel published in 1804. It is characterized by romantic descriptions of nature and deep pessimism, and some of its philosophical passages are highly original. It was translated into English by A. G. Waite in 1903. Sénancour's other writings include *De l'amour selon les lois primordiales* (1805); and *Isabelle,* another epistolary novel (1833).

SENATE, an assembly or council with the highest deliberative and legislative functions. The word is derived from the Latin *senatus* which means literally an assembly of old men. In ancient Rome the senate was the supreme council of state. Originally it was merely an advisory council of patricians, but during the republican period it exercised broad legislative and administrative powers and plebeian members were admitted. The word also is applied to the upper house of the legislatures of certain countries such as France, Italy, Canada, Argentina, and the United States and to the governing bodies of certain universities.

UNITED STATES

In the United States the term Senate is applied to the upper house of Congress and of each state legislature (with the exception of Nebraska which has a unicameral legislature). The state senate, and indirectly also the United States Senate, had its origin in the English colonies—in the governor's council which served two broad functions: (1) executive, to advise the governor and to confirm his appointments; (2) legislative, to act as a second chamber in passing laws. In the early states (after 1776) these councils were transformed into state senates; and they set the pattern for the Senate of the United States as well.

The sovereignty of the states is recognized through their equality in the United States Senate, although the two senators from each state vote as individuals. The Constitution forbids a denial to any state, without its consent, of its equal representation in the Senate.

The original device of choosing senators through election by the state legislature was set aside by the 17th Amendment to the Constitution (May 31, 1913), which provides for direct election by the people. Congress may regulate the times and manner of choosing senators (U.S. Constitution, Art. I, sect. 4), but the fixing of suffrage provisions for voters is left to the states through the provision that "electors in each state shall have the qualifications requisite for electors of the most numerous branch of the state legislature" (17th Amendment). Senators are elected for six-year terms, and a third of the total Senate membership is elected every two years. The governor may appoint a senator if a vacancy occurs and may also call for an election to fill out the unexpired term. It has become the practice in many states to hold such an election with regular elections, thereby saving the expense of special elections.

The qualifications for a senator (Art I, sect. 3) are that he must be 30 years of age, a citizen of the United States for nine years, and a resident of the state from which he is elected. The Senate makes its own rules and is the judge of the election and qualifications of its own members. By a two thirds vote it may expel a senator, and by a majority vote it may refuse to seat an incoming member. Such refusal took place in 1927–1929 when Frank L. Smith of Illinois and William S. Vare of Pennsylvania were denied seats in the Senate because of questions raised concerning campaign contributions. Senators enjoy immunity for what is spoken on the floor of the Senate, and by implication also for what is said in the conduct of committee business. They are exempt from arrest, except for treason or felony or breach of the peace, while going to, returning from, or during a session.

The salary of a senator is $12,500 per year, with an additional nontaxable allowance of $2,500 for expenses. Each senator has an administrative assistant with a salary of $10,000, and is allowed between $20,000 and $30,000 more for clerks, according to the population of his state. Senators receive 20 cents a mile for travel expenses for attendance at a session of Congress, and they have free mailing privileges for the conduct of official business.

The vice president of the United States is president of the Senate, but he may vote only in case of a tie. (In many state senates the lieutenant governor performs a similar role.) The Senate elects from its own membership a president pro tempore who serves in the absence of the vice president and takes over the duties and salary of the president of the Senate if and when the vice president succeeds to the presidency (an eventuality that has occurred seven times). The highest ranking senator (in terms of years in the Senate) from the majority party is generally designated president pro tem. Other officers include the chaplain, secretary, and sergeant at arms.

There are 15 standing committees in the Senate, composed of members from both political parties in the same ratio as these parties bear to the whole body. If a party has 60 per cent of the total number of senators, it will place nine of 15 members on a committee, or three fifths of whatever number the committee may have. The chairman of each committee is the senator having

seniority among the senators of the majority party on that committee.

In lawmaking function the Senate is coordinate with the House. Even the privilege of the latter body to originate money bills is of little importance in the light of the Senate's power to amend any bill. The special powers of the Senate are of tremendous significance. These are executive in nature: (1) power to ratify a treaty by a two thirds vote and (2) power to confirm presidential appointments by majority vote. The practice of "senatorial courtesy" has in effect transferred appointing power over many positions to the individual senators. By it the Senate will not confirm an appointment of an officer to serve in a federal position in a given state—such as federal judge, attorney, marshal, collector—if such person is not acceptable to the senator (or senators) from that state. This principle once led to the rejection of a candidate for a position on a regulatory commission having national scope, because the appointee resided in the state of an objecting senator.

Almost unlimited debate is the practice in the Senate. Cloture—an agreement to limit debate and to adhere to a specified time for a vote—is possible under certain conditions. If 16 senators sign a request, there must be a vote on a cloture resolution which becomes effective when approved by a vote of two thirds of the total membership, namely 64 senators.

After impeachment proceedings have been started by action of the House of Representatives, the Senate sits as a trial court. If the president is impeached, the chief justice presides over the Senate. Conviction of impeachment by a two thirds vote of the Senate carries the penalty of removal from office and disability to hold any other office under the United States. A person so convicted is still subject to criminal prosecution.

After 1793 the Senate changed from secret to open sessions, though it still on occasion employs "executive sessions" for consideration of confidential data. (See also CAUCUS; CONGRESS OF THE UNITED STATES; HOUSE OF REPRESENTATIVES.)

SPENCER D. ALBRIGHT,
Department of History and Political Science, University of Richmond.

SENDAI, sĕn-dī, city, Japan, capital of the Miyagi prefecture, on northern Honshu Island, near the east coast, about 190 miles northeast of Tokyo. The largest city in northern Japan, Sendai is an important educational center with Tohoku Imperial University, founded in 1907, and the Industrial Art Research Institute, founded in 1928. It also is a manufacturing center for silk textiles and yarn, lacquer ware, and pottery. Woodworking is carried on, and there are sake and beer breweries. Sendai was the stronghold of the 17th century feudal lord Date Masamune, and there are ruins of his daimio castle with a memorial to him. Pop. (1947) 293,816.

SENEBIER, sĕ-nĕ-byā′, **Jean,** Swiss naturalist: b. Geneva, Switzerland, May 6, 1742; d. there, July 22, 1809. After some years in the ministry, he became a librarian in Geneva in 1773, and at the same time began the study of plant physiology, to which he made important contributions. His discovery that plant nutrition is dependent upon sunlight was published in his *Physiologie végétale* (1782–1788) and other works. Among his major writings were *Histoire littéraire de Genève* (1786); *Essai sur l'art d'observer et de faire des expériences* (1802); and *Rapport de l'air atmosphérique avec les êtres organisés* (1807).

SENECA, sĕn′ĕ-kà, **Marcus** (or **Lucius**) **Annaeus** (called SENECA THE ELDER), Roman rhetorician: b. Corduba (now Córdoba), Spain, 54 B.C. ?; d. 39 A.D. The father of Lucius Annaeus Seneca, he wrote ten books of *Controversiae,* discussing 74 imaginary legal cases and methods of presenting them. An epitome of the whole and five of the ten books are extant. His *Suasoriae,* of which one book is extant, contains rhetorical exercises. He also is the author of a lost work on the history of Rome.

SENECA, Lucius Annaeus, Roman philosopher and statesman: b. Corduba (now Córdoba), Spain, 4 B.C.?; d. near Rome, 65 A.D. As his family was wealthy and of equestrian rank, the boy was brought to Rome to be educated for the bar and an official career. He also attended with enthusiasm the lectures of several noted Pythagorean, Stoic, and Cynic philosophers. He gained great fame for eloquence and entered the Senate through the quaestorship; but in 41 A.D., at the instance of the Empress Messalina, who accused him of an intrigue with Julia Livilla, sister of the late Emperor Caligula, he was banished to Corsica. From there he sent to his mother, Helvia, the charming *Consolatio,* but exhibited little fortitude in his exile. Finally, in 49, Agrippina, who, after the execution of Messalina, had married the Emperor Claudius, secured Seneca's recall that he might act as tutor to her son Domitius (later the Emperor Nero), then 11 years of age. At Nero's accession in 54, Seneca wrote the curious political satire (still extant) on the death of Claudius, commonly known as *Apocolocyntosis,* meaning "pumpkinification," a word formed upon the analogy of *apotheosis,* "deification." During the first years of the new reign, Seneca, in conjunction with Sextus Afranius Burrus, prefect of the Praetorian Guard, was, on the whole, successful in keeping Nero within the bounds of humanity. Agrippina, ambitious and cruel, was determined to rule the state through her son, and Seneca seems to have palliated the latter's excesses in order to destroy his mother's influence over him. Finally, when Poppaea Sabina, with whom Nero had become infatuated, induced him to order the assassination of his mother, Seneca wrote for the emperor a letter to the Senate, asserting that Agrippina had conspired against his life, and had committed suicide upon being discovered. The death of Burrus in 62 made Seneca's position quite insecure. Nero fell into the hands of men like the infamous Ofonius Tigellinus; money was needed to meet his extravagant expenditures and Seneca had become enormously wealthy. Foreseeing his probable ruin, he offered to resign to Nero all that he had, and, upon receiving a declination, couched in terms of specious affection, retired into the country and lived with utmost simplicity. In 65 he was implicated in the conspiracy of Gaius Calpurnius Piso and was ordered to commit suicide. With his wife, Paulina, who insisted on dying with him (see the affecting account in Tacitus, *Annals,* XV, 60-64), he opened the veins of his arms. Paulina's life was barely saved by her slaves; Seneca, after suffering prolonged

agony, during which he displayed the utmost serenity, was finally suffocated in a vapor bath. "Nothing in life became him like the leaving it." He was undoubtedly an earnest seeker after truth and right. The Roman world was much his debtor for the wise and humane administration of the state during the "golden quinquennium" of Nero; but he lacked real strength of character, and in his connection with Nero too often acquiesced in the doing of positive evil that a greater good might be accomplished. As a man of letters, he is incomparably the most brilliant figure of his time. He was an extremely prolific writer, his subjects are exceedingly varied, the ideas usually nobly conceived and eloquently expressed. In striking contrast to the periodic style of Cicero, he loves short, epigrammatic sentences. He is an expert in the use of every variety of rhetorical ornamentation, which, in harmony with the prevailing taste, he carries to excess. Though by no means a profound thinker, he is broad-minded and sympathetic in his presentation of the ethical principles, Stoic in the main, by which man's daily life should be guided. He was, indeed, by certain Fathers of the Church believed to have been a Christian, and there are still extant 14 letters, undoubtedly spurious, of a correspondence with Saint Paul. His moral essays embrace 12 so-called dialogues, *On Peace of Mind, On Anger, On the Shortness of Life,* etc.; 3 books *On Clemency,* addressed to Nero; 7 *On Benefits,* and 20 books of *Letters to Lucilius.* With these may be grouped the seven books of *Naturales Quaestiones,* which handle physics as a basis for ethical reflections. We possess also nine tragedies, composed rather to be read aloud than to be acted, and so rhetorical in substance that, though fine passages are not lacking, they are rather declamations than real poetry. They had, however, a great influence upon the drama of the 16th century.

Bibliography.—The best text of the prose works is by F. Haase in the Teubner series (1893–95); of the tragedies, by F. Leo (Berlin 1878–79.) The *Apocolocyntosis* has been edited by A. P. Ball (New York 1902). Consult also Merivale's *History of the Romans under the Empire* (cc. 50, 52-24); Zeller's *Eclectics* (London 1883); Farrar's *Seekers after God* (London 1886).

Nelson G. McCrea,
Professor Emeritus of Latin, Columbia Univ.

SENECA, a tribe of North American Indians belonging to the Iroquois family, and one of the Five (later Six) Nations League of the Iroquois, founded about the year 1570. Their own name is *Tsonondowanenaka,* or *Tsonondowaka,* "people of the great hill or mountain," probably referring to the lofty eminence south of Canandaigua Lake. The term Seneca is a Mohawk rendering of this latter name, which has passed through Dutch to English hands. With the Mohawks and the Onondagas, the Senecas constituted the elder phratry of tribes in the social and political organization of the confederation, while the junior phratry was composed of the Oneidas and the Cayugas. The earliest known council fire of the Seneca people was established south of Lake Canandaigua, while their territory comprised the region environing Seneca and Canandaigua lakes and extended westward to Genesee River. As a member of the League, the Senecas were called *Honĕñninhohoñte,* signifying, "They are fixed to a door or door-flap," denotive of the fact that the Seneca people were the political doorkeepers of the League, not because, as commonly asserted they stood at the western frontier of the territory of the confederation, but because being at first averse to joining the League, they were finally persuaded to do so by having the honor of the office of doorkeeper and of official executioner bestowed upon them. Their last two League chiefs or rulers were charged with the duty of ascertaining the good or evil designs of any alien who might seek to enter the jurisdiction of the confederation. It was the policy of the Dutch of New Netherland to maintain an alliance with the League to guard against French encroachments. After 1664 the English pursued the same policy.

During the American Revolution the Senecas espoused the cause of Great Britain against the colonies. Today the Senecas are represented by several different bodies of people dwelling in diverse places and under various forms of government. In New York, according to a Bureau of Indian Affairs report of 1945, they numbered 2,879, scattered among the Tonawanda, Cattaraugus, Allegheny, Onondaga and Tuscarora reservations. There is a remnant in Pennsylvania, on the Cornplanter reservation, and about 300 in Ontario, chiefly on the Grand River reservation. In addition there were 524 so-called "Senecas" in Oklahoma, but these are not included with the foregoing, as it is doubtful whether they were ever true Senecas. The earliest estimate of the numbers of the Senecas, in 1660 and 1677, give them about 5,000. In 1825 those in New York were reported at 2,325. Morgan, 25 years later, estimated them at 2,712, with over 200 more on the Grand River reservation in Canada. About the same estimation was given in 1909.

Skaniadariio, or Handsome Lake, the founder of the reformed pagan Iroquoian religion in vogue today among the various northern Iroquoian peoples, was a Seneca. On the migration, or probably expulsion, of the Awenrehronon from the headwaters of Genesee River, New York, in 1639, and on the later defeat of the Neutral Nation, about 1649–1650, and of the Eries about 1654–1657, the Senecas moved some of their settlements and colonies westward toward Lake Erie and along the Allegheny River. In 1657 there were 11 different alien tribes or peoples represented among the Senecas, thus indicating how well they exercised the right of adoption to replace their great losses in the almost interminable wars of the League, which had then lasted about 75 years. Of the several tribes formerly constituting the League of the Iroquois, the Senecas are the most progressive in the arts and knowledge of civilization. With incidental exceptions, the history of the Senecas previous to the American Revolution is virtually that of the League. See also Iroquois League.

Consult Parker, A. C., *Analytical Story of the Seneca Indians* (1925), and publications of the Bureau of Indian Affairs, Department of the Interior.

SENECA, town, South Carolina, in Oconee County, altitude 950.4 feet; on the Southern and Blue Ridge railways; 125 miles northeast of Atlanta, Ga. An agricultural and textile manufacturing community, its largest industrial establishment is the neighboring Utica-Mohawk Cotton Mill. Settled about 1850 and incorporated in 1874, it was named for the once important Cherokee Indian village of Seneca, four miles distant on the Seneca River. Government is by mayor and council. Pop. (1950) 3,649.

SENECA CAVERNS, underground caves, West Virginia, in Pendleton County, with interesting rock formations which attract tourists from many sections of the United States.

SENECA FALLS, village, New York, in Seneca County, altitude 465 feet; on the Seneca River and the Barge Canal; on the New York Central and the Lehigh Valley railroads; by rail, 41 miles southwest of Syracuse. The falls in the river that give the place its name furnish the power that promoted early industrial development. It is an industrial community in the midst of a region of farms and orchards. Foremost among its industries is the manufacture of pumps. Other products are machine tools, precision tools, rulers and yardsticks, auto ignition parts, women's dresses, and socks. The village has a public library and a municipal hospital. Town annals contain items of considerable general interest. The first woman's suffrage convention, held here in 1848, was called by Mrs. Amelia Jenks Bloomer and Mrs. Elizabeth Cady Stanton. It was for the former "bloomers" were named, although Mrs. Bloomer was not the inventor. Seneca Falls claims to have made the first steam fire engine and the first commercially introduced pumps. First settled in 1787 by Lawrence Van Cleef, a Revolutionary War veteran, Seneca Falls was incorporated in 1831. Its government is administered by mayor and council. The water supply system is owned by the city. Pop. (1950) 6,634.

SENECA LAKE, a lake west of the central part of New York State, about 25 miles south of Lake Ontario (q.v.), into which it discharges its waters by the Seneca and Oswego rivers. It is about 37 miles long, from north to south; and from one to four miles wide. Its depth is about 630 feet and it is 445 feet above sea-level. Geneva is situated at the northern end and Watkins Glen at the southern. At Sampson, a village on the eastern shore 12 miles south of Geneva, a naval training base was established in 1942; it was later converted into an air force base and training center. For a time after 1946 the base was used as the site of Sampson College, a state emergency college for veterans of World War II. Seneca Lake is one of the group called the "Finger Lakes."

SENECA RIVER, a river of New York; flows east from the north end of Seneca Lake to the north end of Lake Cayuga, then turns north and is joined on the left by the outlet of Lake Canandaigua, then turns east, and receives in succession the drainage of the other parallel "Finger Lakes," Owasco, Skaneateles and Onondaga, then turns northwest, taking the name of Oswego River (q.v.) and enters Lake Ontario at Oswego. Length, including the Oswego, nearly 100 miles.

SENECA, or SENEGA ROOT. See POLYGALA.

SENECIO, sē-nē′shĭ-ō, one of the largest known genera of plants, comprising about 1,000 species; it belongs to the family Asteraceae, and is universally distributed. It is, therefore, practically impossible to give a compact description of the generic characters; but it may be said that these plants are annual or perennial herbs, shrubs, or even arborescent, have basal or alternate leaves, and solitary, corymbose or paniculate heads of flowers, usually yellow in hue. These are made up of both radiate and tubular flowers, the latter being five-toothed and perfect, or of the tubular ones alone, on a flattened or slightly convex receptacle. The involucre surrounding each flower head is cylindric or campanulate, with its principal bracts in one series, distinct or slightly united at the base, and encircled very often with a ring of shorter scales. The achenes are mostly terete or compressed, sometimes curiously papillose. After wetting, these papilla put forth pairs of spiral hairs which secrete adhesive mucilage.

The generic name has been derived from the Latin *senex,* an old man, in reference to the tuft of soft bristles surmounting the achene, and mostly white. These parachutes have so well distributed the seeds of the common groundsel (*S. vulgaris*), originally European, that it is found all about the civilized temperate zone as a troublesome weed. It is a more or less glabrate annual, about a foot high, with spatulate pinnatified leaves and rayless yellowish heads in corymbs. It blooms at all seasons, and is often sold in English cities as food for cagebirds. At one time it was even regarded as a love charm, and was said to have formed a part of the Virgin's bed. It was also of old repute for poulticing. *S. aureus* is a charming, slender, American species, with cordate basal leaves, called golden ragwort, and blooming in the spring. Squaw-weeds are other species of *Senecio.*

The plants known as cinerarias, having dark-blue rays—a rare color among composites—are greatly cultivated and hybridized, but not many other senecios are valued in horticulture. Among these are the familiar German ivy (*S. mikanioides*), an easily propagated, rapidly growing, glabrous, twining vine, with small yellow flowers in auxillary or terminal clusters, and glossy, deltoid-ovate leaves; and the Cape ivy (*S. macroglossus*), a beautiful greenhouse climber with golden flowers as large as marguerites and ivy-like leaves. One of the "dusty millers" is *S. cineraria,* a tall perennial, enveloped in white wool, and with small compact corymbs of rayless flowers. The handsome *S. pulcher,* with reddish-purple rayed flowers, of strong growth and cobwebby foliage; the great *S. japonicus,* over five feet high, and extremely ornamental, with its large palmate leaves, and large yellow flowers; and *S. petasites,* valuable for its large panicles of big, yellow fragrant flowers, blooming in midwinter, are also cultivated.

SENEFELDER, zā′nĕ-fĕl-dĕr, **Aloys,** Bohemian inventor of lithography: b. Prague, Nov. 6, 1771; d. Munich, Bavaria, Feb. 26, 1834. The son of an actor, in early life he tried unsuccessfully to be both actor and dramatist. Having learned something of printing he conceived the idea of inventing a process of his own, and was finally led by accident to his great discovery of lithography (q.v.). Subsequently he made important improvements, contrived a press, procured a patent and set up an establishment, which he carried on successfully. In 1809 he was appointed inspector of the royal lithographing establishment. He published the *Elements of Lithography* (1819), a curiously illustrated work, which he translated into English and French. *Consult* Nagler, *Aloys Senefelder und der Geistliche Rath Simon Schmidt* (1832); Pfeilschmidt, E., *Aloys Senefelder* (Dresden 1877); Muller, J.,

W., *Invention of Lithography* (New York 1911).

SENEFELDER, Leopold, Austrian physician: b. Vienna, Sept. 25, 1864. He was educated at the Preparatory Seminary of Mariaschein, the Mies Gymnasium Bohemia, and the University of Vienna. In 1888–1889 he served as interne at the Garnisons-Spitale No. 1, Vienna, was physician to the reserves and assistant physician at Rudolf Hospital, Vienna in 1889–1891. He established a practice at Sankt Pölten, Lower Austria, in 1892 and at Vienna from 1893–1905. After 1908 he was lecturer on the history of medicine at the University of Vienna. In 1902 Dr. Senefelder accompanied Cardinal Gruscha to the Jubilee Celebration at Rome. He was librarian and archivist of the Vienna College of Physicians and published *Anathema esto?* (1892); *Die Katakomben bei St. Stephen* (1902); *Die kaiserliche königliche Weiberstrafenstalt* in *Wiener-Neudorf* (1903); *Dispensatorium pro pharmacopoeis Viennensibus in Austria* (1907); *Acta Facultatis medicae universitatis Vindobonensis,* vols., IV, V, VI (1908–1911). He collaborated in *Geschichte der Stadt Wien* (1904) and contributed to various periodicals.

SENEGAL, sĕn-ĕ-gôl′, West Africa, (1) a river which flows into the Atlantic near St. Louis, the capital of the French colony of Senegal, in latitude 15° 48′ north. It is formed by the union of the Hafing and the Bakhoi, at Bafulabé, the former rising in the Futa-Jallon Mountains, southwest of Timbo, and the latter near Wosebugu. From the opposite or western side of the mountain in which the Bafing rises springs also the Falémé, another great branch of the Senegal, which runs north in a more direct course until it joins the united head streams above Bakel. The Senegal is about 1,000 miles long, and is navigable up to the cataracts of Félou in Kassan, about 700 miles from its mouth. A river service from St. Louis to Kayes, 460 miles, is maintained during the flood season, and a railway line has been built from Kayes to Kulikoro on the Middle Niger, where the waters are again navigable. During the last few miles, it forms a delta marked by numerous *marigots* or channels which disperse its waters through the adjacent plains; and its mouth is dangerously barred, so as to be accessible only for small vessels in the dry season. Dredging operations are employed to facilitate navigation. (2) A French colonial possession comprised in the government general of French West Africa, named after the river Senegal. It is bounded on the west by the Atlantic, on the south by the British colony of Gambia and French Guinea, on the east by the Falémé River, which serves as a boundary between Senegal and the French Sudan, and on the north by Mauretania. The capital, St. Louis, about ten kilometers from the river mouth, was founded in 1658 by French colonists who had been trading in Senegal since 1637. The colony was captured by the English in 1758, and retaken by the French in 1779. Again seized by the English during the wars of the Consulate and Empire, it was finally restored to France in 1815. The settlements did not flourish until the appointment of Gen. L. L. C. Faidherbe (q.v.) as governor in 1854. He subdued the Berber chiefs who prevented the French advance inland and annexed their territories. Subsequent governors pursued the same policy; districts were annexed and protectorates proclaimed with extraordinary rapidity, although the two powerful chiefs Ahmadou and Samory occasioned a great deal of trouble between 1887 and 1890. During Faidherbe's administration the capital, originally badly constructed and unhealthy, was transformed. Senegal was reorganized administratively by the laws of Dec. 7, 1920 and Mar. 30, 1925.

Dakar is a fortified naval station and the seat of the governor general of French West Africa; Rufisque, Kaolack, and Ziguinchor are secondary ports. In December 1924, Dakar and its suburbs were constituted a special district under a European administrator subordinate to the governor general. In April 1929, Gorée, a small island off Dakar, was also included in the township. Local self-governing institutions have existed in the communes of St. Louis and Gorée (now Dakar district) since 1872, and in Rufisque since 1880. They are elected councils, the majority of their members being African.

The total area of Senegal is 77,600 square miles and the population is estimated (1941) at about 1,723,068. The inhabitants of St. Louis, Rufisque, Dakar and Gorée are French citizens; the other Senegalese are French subjects. The territory used to be represented in the French Parliament by one deputy, and elected (with Mauretania) two delegates to the Constituent Assembly. It is administered by a governor assisted by a privy council and by the Senegal Colonial Council composed of 44 members, 26 of whom are elected by French citizens and 18 by representatives of chiefs of cantons and provinces. The territory is divided into 12 *cercles,* each under the rule of an administrator.

A railroad, 165 miles long, connects Dakar, Rufisque, and St. Louis; another 450 miles long, extends from Thiès to Kayes and Bamako in the French Sudan. There is river service on the Senegal from St. Louis to Podor, 140 miles, and during the rainy season, from Dakar to Kayes, 484 miles.

Dakar (pop. est. 1938, 100,003) is a very important port of call on shipping and aviation routes between Europe, South America, West and South Africa. It possesses a dry dock capable of accommodating ships 630 feet long. Before World II, an average of 2,700,600 tons of goods were cleared and 4,000 vessels passed through this port. Dakar is also the site of a large airdrome and serves as a seaplane and naval base.

The greater part of Senegal is sandy and flat, with forests in the southern section along the lower reaches of the Casamance River. Peanut production is the chief source of revenue, exports amounting to between 560,000 and 600,000 tons annually, in addition to large quantities supplied for local consumption. Most of this is shipped ready shelled, but one seventh of it in the form of peanut oil. Other agricultural products of Senegal are palm oil and palm kernels supplied to local soap manufactories; corn, millet, rice, sizal, and gum.

There are large numbers of meat and draught animals in Senegal: more than 500,000 head of cattle, 600,000 sheep and goats, also hogs, donkeys, horses, and camels. Gold is mined in the central and upper valley of the Senegal and Falémé rivers. Pottery, bricks, jewelry, and

woven articles are made by Senegalese craftsmen. The territory imports cotton goods, farinaceous products, sugar, machinery, and coal.

SENEGAMBIA, a name formerly given to an extensive region in West Africa and so called from the Senegal and Gambia rivers. The area covered was variously estimated from 400,000 to 700,000 square miles, and the population 12,000,000. Senegambia included not only the colony now known as Senegal but also the coast territory as far south as Sierra Leone. Many races inhabit this territory, the principal Negro tribes being the Yolofs, Foolahs, and Mandingoes, native to the territory between the Gambia and the Senegal. The inhabitants to the north are mostly Moors, who carry on an extensive trade in gum, etc., with the Europeans.

SENEY, sē'nĭ, **George Ingraham,** American banker: b. Astoria, Long Island, N.Y., May 12, 1826; d. New York, April 7, 1893. He was educated at the Wesleyan University and at the University of the City of New York where he was graduated in 1847. He engaged in the banking business and in 1877–1884 was president of the Metropolitan Bank, New York. He lost heavily at the time of the bank's failure in 1884, but later succeeded in partially re-establishing himself financially. Before 1884 his benefactions amounted to about $2,000,000. He gave $500,000 to establish the Seney Hospital in Brooklyn and $500,000 to both the Wesleyan University and the Methodist Orphan Asylum in Brooklyn. He also gave $250,000 to Emory College and the Wesleyan Female College, Macon, Ga., and liberal sums to other public institutions. He sold his famous collection of paintings at auction in 1885, receiving $406,910 for them. From a later collection he gave 20 valuable paintings to the Metropolitan Museum of Art, New York.

SENIJEXTEE. See Salishan Indians.

SENILITY. First we must ask, when does the adult age end and old age begin; and next, when does old age lapse into senility? It is extremely difficult to make exact calculations in figures of these successive periods of human life, for individual differences play a considerable role. External appearance is far from being a sure criterion: an old head may contain the most youthful spirit; decadence does not strike all the organs at the same time; there is a kind of gradation in the progressive enfeeblement of the human economy. That part which we call purely mechanical is first to deteriorate; muscular weakness manifests itself long before the diminution of cerebral activity. From the age of 65, muscular effort may become painful, while the cerebral faculties usually retain all their power and even, more often than not, grow stronger through experience which is intelligence in reserve. There are people who are born old, as there are others who remain eternally young.

Heredity plays a great role, as does excessive work which tends to wear out the organism. The kind of life one leads—the emphasis placed on material enjoyments or on those of the mind—is likewise reflected in the organism.

Attempts have been made to determine for human beings the exact time in the life span when old age succeeds the adult age: Hippocrates declared that it began at 56 years, Louis J. M. Daubenton at 63, and Pierre J. M. Flourens (qq.v.) at 70. These figures lack any correspondence to reality, for the year of a person's life marking the commencement of old age is quite indeterminate; it differs for each individual.

Maximilien P. E. Littré in the *Dictionnaire de Médicine* has thus defined old age: "Period of human life the beginning of which has been set at the sixtieth year, but which may be more or less retarded or advanced depending upon the individual constitution, the type of life one leads, and a multitude of other circumstances." Littré was perfectly right. A person's actual age, the number of years attested by the birth certificate, is an indication which, however, does not constitute a presumption. To be sure, from the age of 65 one may well distrust a man's apparent youth; the majority of men at that age betray a marked decline of vitality. But there are frequent exceptions. During the 20 years of this writer's contest with old age, more than a thousand persons who thought themselves old, and who really were old, have sought his professional advice. Among these patients there were some men of 50 and others of 70 years. At both these age limits they stated that their skin was becoming more and more dry, that their faces were becoming covered with wrinkles, that they were losing their hair. All said that their muscular strength had markedly diminished, their digestions had slowed down. Their memories were less dependable; prolonged intellectual effort provoked a lassitude they had not experienced before; they realized a loss of moral courage, of self-confidence; they felt a general lassitude and preferred repose to activity.

The symptoms of old age are, in fact, partly objective and partly subjective, and reflect the changes produced by old age in the inmost tissue structures where the regression of functional cells and invasion of connective tissue become more and more accentuated.

From the cerebral point of view, old men, before reaching the stage of senility, show no diminution of intellectual capacity. On the contrary, experience and concentration of the mind on various subjects throughout a lifetime tend to make it more penetrating, more profound, to develop a more tolerant spirit and a surer judgment. But the memory begins to suffer lapses; prolonged intellectual effort produces a fatigue and lassitude never experienced in the adult age; the faculty of imagination becomes blunted. Arrived at senility, the most brilliant intellects founder; sensitiveness and response to emotional stimuli progressively diminish.

Disturbances of metabolism and of the distribution of nutritive substances often lead to obesity. On the other hand, in the senile state, in consequence of increasingly accentuated sclerosis of the organs, the body becomes mummified, so to speak. Among old men, the skin of the face is pale, dry, wrinkled, and the hair has turned grey or white; frequently the figure is bowed; the stature shrinks progressively by three or four centimeters between the ages of 65 and 85 years; the muscular strength weakens, the joints lose their suppleness, and the footfalls become increasingly heavy. Sleepiness, especially after eating, is usual. Vision weakens, as well as the sense of hearing. Urinary disorders are manifested in frequent urination, especially at night; inability to retain the urine may even be an added con-

dition of senility. Ordinarily blood pressure increases.

In the state of senility, one lives on for a certain time at a slower pace. When man is not killed by accident or disease, when peacefully he approaches the extreme limit of human life, he dies by inches.

Let us now consider the actual cause of old age—what inmost processes of our tissues determine it.

It would be sheer waste of time to examine all the metaphysical and more or less fanciful theories that have been published on this subject. It would seem that the only way to solve the problem, while remaining on solid scientific ground, would be to make microscopic studies of the organs of men who have died at extreme old age and compare them with those of young or adult men. Apart from the lesion, properly so called, that caused death, the lesion that, so to say, gave the *coup de grace* to the superannuated worn organism, what modifications can we ascertain in the structure of the tissues of the old man? Can we not find the key to the enigma in the fact that thousands and thousands of autopsies of very old people have invariably revealed the same histological modifications: diminution and atrophy of the specialized functional cells of every organ, and augmentation and hypertrophy of the conjunctive cells and later of the fibrous tissue? Here we have the principal fact that explains the diminution of the output of each organ and the resultant general weakening of the body. What strikes one particularly in senile organisms is that in performing an autopsy, the liver and kidneys make a sharp grating sound under the scalpel, their tissues having become sclerotic.

Indeed, the hepatic (liver) cells, which by their multiple role play so important a part in nutrition, are in large part surrounded and, as it were, suffocated by the fibrous tissue. The same phenomenon is observed in the kidney where the epithelial cells, responsible for elimination of noxious products, are similarly replaced in large part by the conjunctive cells. The walls of the ducts most often have lost their elasticity; fibrous tissue and calcareous substances, perhaps coming from the decalcification of the bones, make them hard and brittle. Degenerated cerebral cells are replaced by conjunctive cells.

The skin drys up, the muscles atrophy, grow pallid and shrunken, themselves becoming sclerotic. The connective tissue progressing into fibrous tissue likewise invades all the glands to the detriment of their functional cells, whence there results a diminution of both internal and external secretions. One needs only observe old men of 80 to 85 years to see how frequently they open and close their mouths in order to obtain a few drops of saliva with which to moisten membranes dried by sclerosis of the salivary glands. A general and constant phenomenon characterizing old age and accentuating senility may be described as follows: the number of functional cells becomes rarefied, they can no longer assure the physiological equilibrium, energy disappears, and the cellular yield falls below the minimum necessary for the maintenance of life.

If such are the causes of our old age, senility and death, it remains to be known by what mechanism the conjunctive cells enter all our organs to replace the epithelial cells.

Here is our explanation: the connective tissue forms a supporting mass for the other tissues; among the functional cells existing in all the organs, muscular fibers, and the hepatic, renal, thyroid, and other cells there are conjunctive cells which represent a kind of necessary framework for maintenance of the structure. In all the organs there are epithelial cells, *specialized* cells, responsible for accomplishing the function devolving upon the organ, while the role of the conjunctive elements is limited to supporting the structure of each organ.

Restricted to this merely passive role, besides being less fragile and worn, the conjunctive cells at any age keep their power of multiplication intact, whereas the functional cells, highly differentiated and specialized, wear out much more quickly and tend more and more to lose their power of regeneration. Thus, in each organ at a given moment there would be conjunctive cells endowed with all their reproductive energy, together with functional cells having to a great extent lost that faculty and destined to atrophy. So the balance of the two types of cells is broken.

The terrain gradually yielded by the functional cells is conquered by the conjunctive cells which have retained their power of increase intact. In proportion as the number of specialized cells diminishes, the conjunctive cells replacing them and not being able to accomplish the function of the specialized cells, the organism becomes steadily weaker. It finally succumbs when the number of functional cells falls below the minimum necessary to assure vital equilibrium. After a long and valuable collaboration, an antagonism arises between the epithelial and conjunctive cells. The conflict ends with the victory of the least perfected elements which are unqualified to assure the functioning of our organs. The consequences of this cellular conflict are seen in old age, senility and death. See also Old Age and Its Diseases.

Serge Voronoff,
Director of Experimental Surgery of Station Physiologique du Collège de France.

SENIOR, sēn'yŏr, **Nassau William,** English political economist: b. Compton, Sept. 26, 1790; d. Kensington Gore, London, June 4, 1864. He was graduated from Eton and from Oxford, and in 1819 was called to the bar at Lincoln's Inn. He was the first professor of political economy at Oxford 1825–1830; was appointed a master in chancery in 1836 and resumed his chair at Oxford in 1847. Of his writings, which comprise a number of excellent treatises on political economy, mention may be made of *An Outline of the Science of Political Economy* (1836); *Political Economy* (1850); *Essays on Fiction* (1864); and *Historical and Philosophical Essays* 2 vols. (1865). Books edited after his death are: *Journals, Conversations and Essays Relating to Ireland* (1868); and *Conversations and Journals in Egypt and Malta* (1882).

SENLAC, sĕn'lăk, or **HASTINGS, Battle of,** the one battle in the Norman conquest of England. It was fought Oct. 14, 1066 at Senlac Hill, a few miles from Hastings, between William, Duke of Normandy, and Harold II (q.v.), king of England. Harold's fortified position was attacked at 9 A.M. by the Norman army in three divisions, strong in cavalry and archers, the center led by William in person. The English made a stout resistance with their battle-

axes and other weapons, but part of them pursuing William's flying Bretons, the whole body was led into a trap by the feigned retreat of many of the Norman forces, the disordered ranks of the English being easily overborne by their enemies, who stormed and carried the hill. The death of Harold, who was pierced in the eye by an arrow about sunset, disheartened his men and they shortly dispersed. Battle Abbey was erected by William on the field where Harold fell and portions of it still exist. Among the literary treatments of the event are two poems of Chatterton and a drama by Cumberland. Consult Green, 'The Conquest of England' (1899); Freeman, 'Norman Conquest' (Vol. III, 1876). See WILLIAM I.

SENN, Nicholas, American surgeon: b. Buchs, Switzerland, 31 Oct. 1844; d. Chicago, Ill., 2 Jan. 1908. He was brought to this country when a boy and settled in Wisconsin. He was educated at the Chicago Medical College and the University of Munich, was house physician at the Cook County Hospital 1868–69 and practised medicine in Wisconsin 1869–93, being at one time surgeon-general of that State. After 1893 he practised in Chicago, where he was attending surgeon of the Presbyterian Hospital and surgeon-in-chief of the Saint Joseph's Hospital. He was appointed in 1898 chief surgeon of the Sixth army corps, ranking as lieutenant-colonel of volunteers and chief of staff in the field. From 1884–90 he was professor of surgery at the College of Physicians and Surgeons, Chicago, and after 1890 professor of practical and clinical surgery at the Rush Medical College. He was also professor of surgery at the Chicago Polyclinic and lecturer on military surgery at Chicago University. Among his works are 'Four Months Among the Surgeons of Europe'; 'Experimental Surgery' (1889); 'Surgical Bacteriology' (1889); 'Principles of Surgery'; 'Tuberculosis of Bones and Joints'; 'Medico-Surgical Aspects of the Spanish-American War'; and a 'Nurse's Guide for the Operating Room' (1903).

SENNA, Nelson Coelho de, Brazilian lawyer and author: b. Serro, Minas Geraes, 11 Oct. 1876. He was educated at the Normal School at Diamantina, Historical Institute at Rio de Janeiro, São Paulo, Nichtheroy and Ceará, and the Academy of Juridical Sciences, Ouro Preto. He has been successively secretary of the police and agriculture departments of his native state, professor of Brazilian and history at Mineiro Gymnasium, Bello Horizonte, and vice-president of the council of public instruction of Minas Geraes. He served in the first, second and third Latin-American scientific congresses. He is member of many learned societies both of South America and of Europe. His published works are 'Questões internacionães do Brazil'; 'A Edade da Pedra do Brazil'; 'Elogio literario de José Eloy Ottoni, poeta sacro brasiliero'; 'A Hulha Branca'; 'Los Indios del Brazil'; 'Contes Sertanejos'; 'Paginas de historia religiosa do Brazil'; 'Discursos Academicos'; 'A Bacia do Rio Dôce,' etc. He edited *Annuario Historico e Estatistico do Estado de Minas Geraes* after 1906.

SENNA, a nauseous, bitter but valuable purgative drug, obtained from the leaves of several tropical species of the leguminous genus *Cassia* (q.v.). The officinal species are shrubby plants, with nearly regular, five-parted flowers in racemes and alternate, pinnate leaves subdivided into many leaflets. Alexandrian senna is formed of the leaflets of *Cassia acutifolia,* which are dried by cutting the shrubs until the leaflets shrivel and tumble off. *C. angustifolia* grows in and about Arabia, where it was used in domestic practice by the Arabs, who were apparently the first to introduce the drug to Europe. It is called Indian senna, as it is cultivated in South India. Bombay senna is a very inferior quality of this variety, much mixed with stalks and dead leaves; the variety Tinnevelly, on the contrary, is the largest and cleanest senna in commerce. *C. obovata,* formerly of good repute, producing senna-pods and cultivated in India, is now classed among the inferior qualities and rarely met with except as an adulterant. Still other sennas are known under the name of the port of export, or place of growth. American or wild senna is the *Cassia marylandica,* a perennial abundant in the southern United States, sometimes eight feet high, with obtuse, oblong leaflets, numerous yellow flowers, with clawed petals and long linear pods. It has the qualities of Oriental senna in a lesser degree and was formerly used for the same purposes in popular medicine. Bladder senna is the *Colutea arborescens* and is also a purgative sometimes called bastard senna.

SENNAAR, sä-när', Anglo-Egyptian Sudan, a province extending between the Blue and the White Nile, from Khartum to Fazogl. The Arabs call it the «Island of Sennaar.» Generally speaking, it is a broad plain with occasional granite mountain heights and is at the north steppes thickly overgrown by wild grass and bushes; the southeast has tall forests intersected by fertile valleys. Gold and iron occur, and palms, tamarinds, etc., grow on the plain. Monkeys, lions, gazelles, giraffes, elephants, besides marsh and water-birds, are numerous; also domestic animals. The chief occupation is fishing. The products are rice, grain, melons, tobacco, sugar, senna, ebony and sandal-wood. The climate is exceedingly warm and during the rainy season is unhealthful. The inhabitants are negroes — the Funj, Nubian and Galla, and of mixed races. Sennaar, which was the former capital, stands on the Bahrel-Azrik or Blue Nile. A great irrigation dam across the Blue Nile was completed in 1926. The other towns are Fazogl, Roséres, Wod-Medineh and Khartum. Near the latter town are the extensive ruins of Soda, the ancient capital of the Funj, a negro race who migrated there from Central Africa in 1500 and founded the Sennaar kingdom, which lasted until 1821.

SENNACHERIB, sĕ-năk'ĕ-rĭb, an Assyrian king, son of Sargon, succeeded his father on the throne 705 B.C. Among his first acts as king was the suppression of the revolt of Babylonia and after accomplishing this he directed his arms against the Aramean tribes on the Tigris and Euphrates, of whom he took 200,000 captive. He then reduced a portion of Media, till then independent; placed under tribute Tyre, Aradus and other Phœnician cities; advanced against Philistia, made war upon Egypt and finally marched against Hezekiah, king of Judah, who had revolted. Hezekiah, terrified, yielded in a panic, and paid the tribute exacted, namely, 300 talents of silver and 30 talents of

gold. On his return to Assyria Sennacherib made another attack on Babylonia and afterward reinvaded Judah. Having marched through Palestine he laid siege to Libnah and Lachish and finding that his messengers Tartan, Rabsaris and Rabshakeh had failed in obtaining the submissio.. of Hezekiah, he wrote an intimidating letter to Hezekiah; but before he could bring his forces against the city, according to the Bible record, a visitation from the Lord during the night caused the death of 185,000 of his troops. In consequence of this calamity Sennacherib returned to Nineveh and troubled Judah no more. From Herodotus we learn of the Egyptian tradition regarding the destruction of Sennacherib's host, which is, that a multitude of field mice devoured all the quivers and bowstrings of the enemy and gnawed the thongs by which they bound on their shields. No mention of the destruction of his host is found in the monuments of Sennacherib. This ruler was one of the greatest of the Assyrian kings and was not only a great warrior but also a great builder. His largest architectural work was the palace of Koyunjik, which covered an area of fully eight acres. Of the death of Sennacherib all that is known is contained in the brief Scripture statement of 2 Kings xix, 37 and Isa. xxxvii, 38, from which it appears he was murdered by his own sons. See Assyria; Assyriology; Babylonia.

D., 'Annals of Sennacherib' (Chicago 1924).

SENORA AMA, drama in three acts by Jacinto Benavente, was acted at Madrid 22 Feb. 1908. The story is one of peasant life on the plains of High Castile, a presentation of contemporary rural Spain as brilliant in color, but sordid and dead within, palsied with the degeneracy of a decaying civilization, from which all impetus and inspiration have disappeared, and merely husks of Church and State remain. Few dramas are of equal pessimistic power. As a veracious psychologic study, the play is of great value, depicting the sterility of the retarded country-side which is sunk in jealousies, sensuality and greed, where only the maternal instinct breathes unstunted amid the insentient fields. The minutest details are of unimpeachable realistic veracity. The author avoids any semblance of generalization. Yet in the absence of physical descriptions, the aspect of the Castilian plain and sierra is projected from the austere mentality of the peasantry with a rudeness of coloring and distinctness of outline which the Spanish painters have not surpassed. The sense of the motionless background provided by centuries of Spanish civilization is conveyed with the same economy of means. Upon the technical side the play is one for the artist. In illuminative insight and potency of imaginative suggestion, although a work of pure realism, it rivals in completeness the universality of idealistic art. There is the customary lack of *coups de théâtre,* reinforced by a contemptuous disregard of the conventional conceptions of the stage. The first edition appeared at Madrid, 1908. Consult also Benavente, 'Teatro' (Vol. XVII, Madrid 1909). The English translation is included in the third series of the 'Plays by Jacinto Benavente' (New York 1917 et seq.).

John Garrett Underhill.

SENS, France, archiepiscopal city and capital of an arrondissement in the department of Yonne, situated on the right bank of the Yonne River, 70 miles southeast of Paris. The city contains the cathedral of Saint Etienne dating from the 12th century and a fine city hall, which contains also a museum of precious stones, a library and an art gallery. Manufactures consist chiefly of fertilizers, farm implements, leather, glue, serge, etc., and there is considerable trade in wine, corn, hemp and flax. Sens was known in ancient times as Agenticum and later as Senones and was one of the largest cities of Gaul, vestiges of the old Roman walls still being visible. Pop. about 15,000.

SENSATION. This term is used broadly to designate any form of consciousness which originates immediately from the stimulation of the sensory end-organs of the nervous system (e.g., the eye or ear). This usage fails, however, to distinguish between sensation and sense perception. In the narrower psychological meaning sensation applies to the elementary forms of consciousness originating under the conditions mentioned. Sensations are in this technical sense cognizant of simple sensuous data, such as colors, tones, etc., whereas perceptions are cognizant of objects. For example, we perceive a sunset, a complex visual object displaying various color qualities, e.g., whiteness, redness, etc., of which we become conscious as sensations. These sensations are regarded as simple and incapable of further analysis. We perceive a musical sound when a note is struck upon the piano. This sound is made up of a simple fundamental tone and its overtones. Our consciousness of one of these simple pure tones is a sensation. On these terms sensation is evidently largely an abstraction of the psychologist. Our actual sensory consciousness is commonly cognizant of objects, i.e., is perceptual.

Certain authors extend the meaning of sensation so as to include not only all elementary sense qualities arising directly from sensory stimuli, but also all such qualities when aroused in processes of imagination, as when, for instance, one closes the eyes and gets a visual image of a rose. They speak, therefore, of peripherally and centrally originated sensations. In so far as this usage calls attention to the fact that the sensory and ideational elements are qualitatively alike, whether called out by central or peripheral stimulation, it is justifiable. But well-established custom is violated by the procedure and it may be questioned whether it will endure.

The commonly recognized groups of sensations are as follows: color, including brightness, sound, taste, smell, pressure, heat, cold,

pain, articular, tendinous, muscular, thirst, hunger, sex, circulatory (including tickling, itching, etc.), respiratory and static (dizziness sensations from the semi-circular canals of the ear).

Psychologists are wont to treat sensation under four principal aspects, i.e., quality, duration, intensity and extensity. Of these four quality is generally considered most basal. A sensation of tone, for example, may vary in duration without appreciable alteration of the pitch, which constitutes its most essential quality. Again, a color sensation may under certain conditions vary in extent without noticeable variation of quality. But a sensation which had no duration or no intensity would obviously be no sensation at all, and in general, if any aspect which a given sensation can manifest be reduced to zero, the whole sensation vanishes. Certain psychologists maintain that every sensation possesses all these aspects, but probably the majority hold that auditory sensations at least, and perhaps a few others, like smell, are lacking in extensity. Certain interesting facts concerning the relations of sensation intensities to one another are formulated in Weber's and Fechner's laws. (See WEBER'S LAW). According to Weber equal differences in sensation intensity are produced by relatively equal differences in stimulus intensity. If we place a weight of 20 grams upon the hand, we shall notice no change until we have added another whole gram, i.e., of the original stimulus. If we take a weight of 100 grams, we must now add not one gram but $\frac{1}{20}$ of 100 grams or 5 grams, before we notice a change. The same sort of relation holds for a number of the senses within the medium ranges of intensity.

Sensations depend upon the stimulation of specific end-organs connected with specific brain centres. No one ever gets visual experiences who does not possess an optical centre in the cerebral cortex and who has not at some time possessed a functioning retina. No one ever gets auditory experience without a similar use of the ear and the auditory cortex and the same sort of thing is true for each of the sensations.

The stimuli which produce sensation are classified as adequate and inadequate, internal and external, mechanical and chemical. The only pair which requires any explanation is the first. Each sense organ is fitted to respond primarily to some special form of physical stimulus, e.g., the eye to light, the ear to sound, etc. Such stimuli are called adequate. In addition to these adequate stimuli, however, the senses can be aroused by other forms of stimulation designated inadequate. Thus an electric current conducted to the frontal region of the head may produce sensations of light. Pressure on the eyeballs similarly occasions color sensations. It may be added that sensations often continue after the stimulus is removed. Such sensations are known as after-sensations. In the case of vision they present very remarkable characteristics and are commonly called after-images.

Sensations combined in various ways and reinstated in the form of memory and imagination furnish the basis of all our ideas. They are accordingly the foundations upon which rests the whole structure of knowledge. To understand their function in this particular it must be borne in mind that in actual experience they are not mere naked qualities, but that they serve to convey meanings and that it is in this manner that they achieve fundamental import for mental life.

Retired President of Yale University, New Haven, Conn.

SENSATION, Organic. The term organic sensation is nowadays applied broadly to all those sensations which originate from internal bodily stimulations. They are called forth by mechanical, chemical and thermal changes in the organism. Among the sensations which are commonly held to belong to this group may be mentioned pain, pressure and temperature from the interior of the organism; sensations from the muscles, tendons and joints; sensations from the alimentary canal; sensations from the circulatory, respiratory and sexual organs; and finally sensations which are supposed to originate from the semi-circular canals of the internal ear. These sensations are sometimes distinguished from the other forms of sensation like vision and hearing on the ground that they convey to us primarily a knowledge of the state of our own organism rather than knowledge about the external world. This distinction is, however, only roughly accurate.

The sensation qualities which originate from these senses can be described only with approximate accuracy, for psychological analysis has not succeeded as yet in unraveling all their complexities. Pain, pressure and temperature are familiar experiences requiring no description. From the muscles we obtain sensations which suggest dull pressure, becoming under conditions of fatigue somewhat unpleasant and in condition of cramp leading to distinct pain. From the tendons we obtain sensations which inform us of the movement of our limbs and particularly sensations of strain and resistance. It is generally held that from the joints we receive important sensations which also inform us of the movements of our limbs and in particular make us aware of their position. Certain authorities have called in question — both on anatomical and psychological grounds — the significance of the articular sensations. These sensations from muscles, tendons and joints commonly occur together and are sometimes spoken of in a group as the «muscle sense» or the kinæsthetic senses. Experimental devices are necessary in order to isolate them from one another. The circulatory processes are probably responsible for such subjective sensations as feverishness, shivering, «pins and needles,» itching, tingling and tickling. Of course certain of these sensations are at times called forth by direct external causes. The heart itself occasionally gives rise to very distinct sensations, commonly of a painful character. The respiratory organs are probably responsible for our feelings of suffocation, of «stuffiness» and closeness as well as for those of freshness and stimulation in the air. The alimentary canal occasions at least three specific qualities: hunger, thirst and nausea. Undoubtedly the processes of secretion and excretion affect the general tone of consciousness from time to time,

although, with the exception of the sexual organs, it is difficult to say whether they produce any real sensations apart from those already mentioned. The respiratory, circulatory, alimentary and sexual sensations are sometimes spoken of as the «vital sensations.»

The semi-circular canals together with the vestibular portion of the internal ear are commonly regarded as responsible for our impressions of the movement of the body as a whole; but it seems certain that under ordinary conditions other senses contribute to these impressions and only in the case of dizziness is it at all clear that the sensations themselves are different from those hitherto mentioned. It is in any case reasonably certain that these organs constitute part of a reflex system by means of which the body equilibrium is maintained.

The term common sensation, or sometimes common feeling, has been applied more or less indefinitely to this whole organic group of sensations with special reference to the fact that our general feelings of vigor, health, discomfort, depression and so on depend upon them. When these terms are used at present they are more commonly applied to sensations like pressure and pain, which are conceived as widely distributed over the body and therefore as more or less common to the impressions gained from various sense organs.

Organic sensations are undoubtedly dependent like other sensations on the stimulations of sensory end-organs connected with centripetal neural pathways leading to the brain. These end-organs instead of being placed upon the surface of the body, like those of the more familiar senses, are imbedded in the various deep-lying tissues of the organism. A marked peculiarity of many of these sensations is their tendency to set up massive, widespread irradiating effects often quite remote from the seat of stimulation. This is probably brought about by means of the intimate connections of many of these organic sensory nerves with the sympathetic nervous system. This is less true of the kinæsthetic sensations and certain forms of pressure than of the remaining members of the group. Pain affords many striking instances.

The organic sensations play an extremely important part in the phenomena of feeling and emotion. In such emotions, for example, as fear and anger it is clear that a large part of the content of our feeling is made up by sensations of this character, e.g., sensations of tingling or flushing which come from circulatory changes in the skin, painful sensations from the region of the heart, sensations of choking which come from the respiratory passages, sensations of trembling which come from the motor mechanisms, and so on. The James-Lange theory of emotion makes the reflex stimulation of these organic sensations the cardinal fact in emotion whereby it is distinguished from other forms of consciousness.

These sensations are also held to possess distinct significance for the processes of memory and recognition. It is thus maintained by certain authorities that the characteristic psychological process when we recognize a familiar object is found in the arousal of certain of these organic sensations which are called forth by familiar objects, whereas a different set of organic qualities is aroused by unfamiliar objects. It seems fairly certain in any event that the process of recognition is characterized by the presence of a definite mood and the specific qualities of our various moods are by general consent of psychologists determined by the presence of definite organic sensations.

Ribot and others urge furthermore the existence of «affective memory.» By this they mean that in addition to our ability to recall ideas and in addition to our ability to remember whether any given past experience was agreeable or disagreeable, we possess the capacity actually to reinstate in some measure the original affective coloring of a past experience. This is brought about, they maintain, either by our capacity freshly to arouse the organic sensations which originally belonged to the experience, or by our ability to arouse the images or mental copies of these sensations. Certain psychologists deny the existence of these images. Without attempting a discussion of the merits of this doctrine it is safe to say that individuals vary vastly in the degree to which they actually possess this capacity of fresh arousal of either the organic images or sensations characterizing a former experience.

Aside from the particulars already mentioned organic sensations possess small value for the cognitive side of mental life. They bring us relatively little exact knowledge and in conditions of health come only infrequently to clear consciousness. On the other hand they are ordinarily marked with distinct feeling-tone, are definitely agreeable or disagreeable. Under conditions of health they seem to afford the basis of our feeling of well-being, a feeling which is sometimes vivid but usually dim and vague. They are very disagreeable and painful when the bodily processes are overtaxed or disturbed in any way and it is in connection with such experiences that we most often find them coming distinctly into the foreground of the mind. The discomfort of indigestion, extreme fatigue and headache will illustrate the point.

Although their value for our knowledge processes is small, their significance for the life of impulse and volition is tremendous. The two great impulses represented by hunger and sex may suffice to illustrate this side of the subject. All our processes of will and the whole substructure of character are honeycombed with influences which originate in these impulses, and the impulses themselves are but the motor expressions of stimulations from organic sensations.

JAMES ROWLAND ANGELL,
Retired President of Yale University.

SENSATIONALISM, *in philosophy* the doctrine that our ideas originate solely in sensation and consist of sensations transformed Locke has been classed with Condillac and other philosophers of the 18th century as holding the doctrine of sensationalism; but Locke teaches that «all human thoughts, even the most complex and abstract, are due to experience»: they are all made up of «simple

ideas,» and are due to phenomena of which we are percipient in the five senses, or else they are due to reflection on «the operations of the mind.» Condillac most distinctly refers all ideas to sensation. He supposes a statue organized within like a man, but as yet without sensibility. He endows this statue with one sense after another till it becomes perfectly a human being, and holds that it then would possess exactly the same ideas as ourselves, though in its first state it had no ideas.

SENSE-ORGANS. See ANATOMY, COMPARATIVE.

SENSES, in psycho-physics, anatomy, physiological-psychology and in philosophy, specialized nervous apparatus and the psychological process by the stimulation of which (or its equivalent) qualitatively distinct sensations are produced. Sense is equivalent to the Latin word «sensus,»* the Italian «senso,» the French «sens,» and the German «sinn.» A sensation — for to understand the import of «sense» it is necessary that one should understand «sensation» also — is that process of nervous or quasi-nervous irritation which can only be accounted for by the present operation of a stimulus or its equivalent upon a sentient being. It is the feeling that takes place while a sense-impression is made. A sense-impression is the effect of an event upon sentiency. What is that sense-perceived something, an event in which affects sentiency? It must be answered that it is designated by what is really one of the vaguest concepts in the whole realm of thought, an abstract notion, the idea of matter. For present purposes we shall define matter as anything which can affect the senses. Upon which motion we may build up one conception of «sentiency,» and define it as the «matter perceiving,» as an American philosopher, Dr. Paul Carus, defined it.

The use of «sense» as equivalent to «consciousness,» as in the phrases «time-sense,» «sense of responsibility,» and in ‹sense of the heart› (the so-called *occult sense* of the mystic, Jonathan Edwards, who claimed by it one might know spiritual worth, truth, etc., by a kind of intuition), is confusing and inaccurate. (Consult Baldwin, ‹Dictionary›). States of consciousness are nothing but the states of awareness or feelings connected with not only sensation, but also with perceptions, ideas and volitions. These states constitute the entire «subject.» Memory and imagination are at times defined as senses — internal senses; but this distinction is psychologically of no particular importance. Sensation (in German «Empfindung,» in French «sensation,» and in Italian «sensazione»), is a word confined by definition to those sense-impressions fully realized in consciousness, and this definition excludes the cerebral process of image-reproduction, etc., which is normally aroused in the absence of stimulation. It is at all times a very great advantage in thinking to recall that the terms «sense,» «sensation,» and even «matter» are, after all, at best concepts arrived at through a process of abstraction. For even so great a psycho-physicist as Ernst Mach (to cite one example) used «sensation» as synonymous with «reality» itself. Man generalizes, he marks and describes those features which a set of events has in common; but while generalizations are symbolized by mere words they deal with the events which are aglow with life or action. «Sense,» «sensation» and «matter» are such mental symbols, and they represent not the whole of reality, but at most only a single set of its features respectively.

Organism developed from protoplasm whose potentialities are four in number; and an organism whose histologic units are four would seem to have also four psychic facultative manifestations. Irritability, contractibility, metabolism and reproduction in the cell correspond to epithelium, muscle, connective tissue and nervous tissue in higher animal forms. In the mind they become sense, will, understanding and ideation. Epithelium has its analogon in «sense,» and ideation, its parallel in «tissue formation,» or «reproduction.»

Professor Ernst Haeckel in one truly profound lecture, beautifully explains how each animal cell, and even each plant cell, is endowed with a peculiar kind of «soul-life» of its own. In higher animal forms, he tells us, there are formed through division of work special «soul-cells» of «nervous-substance.» The lower we descend in the animal series the more the nervous system is simplified, and more, too, the nervous elements separate from each other, until finally they disappear merged in the mass of an undifferentiated organism. It is the same with all the other apparatus, with all the anatomical elements; and it would be as absurd to refuse sentiency to an animal because it has no brain, as to declare it incapable of nourishing itself because it has no stomach. Sentiency itself originates through contact and interaction of matter with matter. And the truth is that the nervous system arises like other systems from division of labor. Lower creatures are sentient, the higher brute animals conscious, but self-consciousness is found only in man who alone is aware that he knows.

To Demosthenes, the eloquent orator of classic antiquity, is ascribed the statement that all the senses are modifications of the sense of touch. Sentiency is always an awareness of objects in external material existence. So too is it with the senses. Kant distinguishes two sources of knowledge — sensation and pure reason. Sensations are incidental and particular; come to us singly in a haphazard way and without affording any information concerning a necessary connection. The character of pure reason alone is the intrinsic necessity and universality of its statements. The sequence in which the specialized apparatus of each sense appeared in the evolutionary process is unknown. Touch, taste, sight, hearing and smell are at times said to represent that sequence. The senses originated through irritation received at the periphery of

* One may recall that the Latin names of the five senses, with the word " sensus " itself, are all of the fourth declension in that tongue, and are thus nouns having one form only to express both numbers. Awkward as is any form of these Latin words in English, students have come to it, and speak of " sensuses," and even of " visuses," " sensus," " visus," " auditus," " gustus," "olfactus," and " tactus," whether employed as Latin or as English words, are, however, all nouns which reveal number only in the accidence of words with which they are grammatically connected. See the protest of H. H. Wilder, " Desmognathus Huscus [sic] ", in *Science* (19 April 1918, New York); and the Reply to Professor Wilder by T. L. Casey in the same journal (21 June 1918).

an organism. Taste is most nighly differentiated in man. Sight is perhaps keenest in birds and bees. Hearing is the strongest faculty of the hare. Smell is the peculiar faculty of the blood-hound and of the ant. Touch attains a high degree of perfection in the trunk of the elephant. The bee is sometimes said to possess a peculiar faculty, an «hygrometric sense,» as it is named. This quality or power of the bee is attributed to the little animal owing to an inference based on its undeniable power to «detect» and avoid a coming storm. It is just possible, however, that the bee employs sight rather than an hygrometric sense to detect the approach of storms, and to avoid them.

Through experience, a nerve, the optic nerve, became adapted to waves of ether. There irritations are transferred to the optic ganglions, and there possibly the disturbance is accompanied by the awareness called light. So also a nerve, the auditory nerve, became adapted to air waves. The irritations effected by these waves are transferred to the auditory ganglion, where possibly the disturbance is accompanied by the feeling known as sound. All other nervous cells of specialized sense, whether olfactory (or of smell), gustatory (of taste), or tactile (of touch), arose in evolution and function in a way similar to the senses of sight and hearing. Along the whole line of nervous fibres, from the point where sense-impressions enter to the place where muscular contraction such as usually follows the transmission of a shock from sensory to motor nerves, there is, physiologically, one uninterrupted chain of nerve motion. Yet the feeling or consciousness which accompanies a sensation is no motion.

One does not exhaust the number of sensations, however, if indeed one does the number of the specialized senses, in any mere enumeration of the sense-organs. These latter are the eyes, ears, nose, tongue and skin. In addition to the sensations of vision, hearing, smelling, tasting and touching (all of which Aristotle enumerated long ago), are to be mentioned, if only for greater completeness, pressure, temperature, pleasure, pain, muscular sensations, sensations in the ears, and sensation from the inner contents of the body. Pain and pleasure (see IRRADIATION), muscle sense, sensations from the semi-circular canals and vestibules of the ear, hunger, thirst, sexual-sense, fatigue, and sensations from the visceral organs — are internal, or organic sensations. Suffocation, internal warmth and chilliness are others of the same class. In all one perceives the characters of ordinary sensation, the sense-process or psychic function involved in the apprehension of anything by the senses.

As belonging to the outer world one speaks of sensations and their complexes arising in our own body as organic sensations, because we locate them in our own body. Examples are sensation of fatigue of our muscles, and the pressure and pain sensation of our inner organs. The relatively uniform elements of touch and organic sensations are distributed among sensations of pressure, warmth, cold and pain. In contradistinction to these, the special senses of hearing, seeing, smelling and tasting present an abundance of sensations, each of which according to its peculiar constitution is called a quality of sensation. Each such quality is variable in its intensity. Qualities of sensations all refer to the objective world. Our own body, to which touch and organic sensations relate, forms in contradistinction to our consciousness (the subjective reality, our real selves) a part of the outer world;— nearest to us indeed, but still a mere part of the objective or external world. Subjective existence is constituted of those feelings or states of consciousness whose activity is no motion. Objective existence is represented by things whose activities are motions. Man has abstracted from a group of sense-perceptions an idea of his «body.» The group of facts so collectively designated as «body,» the action of which appears in constant connection with and as a condition of our consciousness, is kept in health only through constant renewal of its waste products out of the resources of the objective world, of which it is a part.

Sensations, while they are psycho-physical processes normally due to actual stimulation, can occur without any stimulation being present. Delirium and the manifold examples of what are wrongly called sense-illusions are cases in point. Audition colarée, which seems to associate sound with color, is an example of excessive associative power, a result of insufficient balance of associative capacity, whereby the less near is approached because of the loss of what commonly should have been associated. When an adult professes to perceive a color, for example, every time he hears a letter of the alphabet named, it is hypothetically safe to say that were an investigation undertaken, it might disclose that the colors which such an adult professes to «hear» are the very colors in which the letters were printed on the blocks from which as a child such an adult learned his letters. There is no recorded instance worthy of credit of what has been styled «sense-transference,» either concerning people in the somnambulistic state (as has been claimed) or out of it. No person ever read, tasted, heard by the fingers, or the stomach or any parts of the body other than through those organs by which reading, tasting, hearing, as functions of the sense organs, are naturally performed. Those «higher» phenomena of clairvoyance prevision, retrovision, introvision and telepathy do not (in the ordinary sense of these words) exist at all. Mysticism of this sort colors the thought of only those people who in regard to some matters «spiritual» have strong convictions based on no evidence. The recollection of a sensation is nearly the same (but not the same) as an original sensation. For were it a sensation with a present stimulus then one might actually freeze to death through frigid imagination. Such recollection resembles the original sensation only (as being like it) a psychic event. By means of our senses we secure mental impressions through certain organs,— sensory or sense-organs,— concerning the world of objects, including impressions concerning changes in the condition of our bodies: and nothing more. There is a telepathy, or «far-feeling,» however, which does not stand in miraculous contradiction to the mechanical interconnection of cause and effect in the external world. In and through our eyes most distant stars are seen. Only in this sense has telepathy any claim to recognition by scientific psychology. Yet the feeling feature of sensations is

purely subjective. Things are mirrored in our eyes; sounds are heard with our ears; and abstract notions are formed mentally to represent them. It would of course be very absurd to expect that the things represented in a sensuous-manifold should migrate bodily into our heads; and yet it would be equally as absurd as some far feeling telepathists profess to believe, that things or objects in the external world could be felt without the normal use of the sensory organs.

Though no animal has specialized more senses than five, many are much more sparingly endowed. Of very great importance as regards our enjoyments and our sufferings all knowledge besides has its roots in sensation. «All our knowledge,» observed Gassendi long ago to Descartes, «appears plainly to derive its origin from the senses, and though you deny the maxim 'Quicquid est in intellectu processe debere in sensu,' yet this maxim appears nevertheless to be true; since our knowledge is all ultimately obtained by an influx or incussion from things external; which knowledge afterward undergoes various modifications by means of analogy, comparison, division, amplification, extenuation and other similar processes which it is unnecessary to enumerate.» (Gassendi, in 'Objectiones in Meditationem Secundam').

Hallucination is a misinterpretation of sensations. The feelings are real enough in such cases; but the representations concerning what are supposed to evoke these feelings are not valid. Sensations become precepts, many precepts of one kind become concepts. From these concepts by the help of the reason abstractions are drawn. Thus all the objects of our surroundings are mirrored in their relation toward us and among themselves in the living substance of the brain.

Bergson attributes to intuition a peculiar power. (Consult 'Creative Evolution,' English trans. 1913). That there is something unique and new at every moment may be granted. Further, that it is also true that this cannot be fully expressed by means of intellectual concepts may be also granted. Only direct knowledge can acquaint us with what is unique and new. But direct acquaintance of this kind is given fully in sensation and does not (as Bergson contends) require any special mystical faculty of intuition, for its apprehension. It is neither intellect nor intuition (in the Bergsonian sense), but sensation that supplies new data. Bergson makes much of evolution. It must be pointed out that it is only through the intellect that evolution can be known. If the intellect is misleading the whole of man's biological ancestry which we know through the intellect is presumably an erroneous inference. Bergson's advocacy of intuition as against intellect is thus a self-stultification.

Kant distinguishes two sources of knowledge — sensation and pure reason. Yet the ultimate data of experience and the bases of all knowledge are sensations. These data of experience are the several states of consciousness, the elements of which are the sensory impressions, which fully realized in consciousness are sensations. Experimenting with the purely formal is indeed a kind of experience, and may be distinguished as inner experience, just because it is not merely a subjective process, but ideal. Objectively and scientifically the external objects of one's sensations are those sensations measured in terms of what we suppose to be their causes. We no longer feel, owing to long practice of projection, our sensations as states of consciousness, but conceive of an independent reality as given immediately. But sensation is nevertheless only the psychical feature of the data of experience, and in the idea of a sensation, the material and physical stimulus is excluded. All one's sensations are in one's self, not in their cause. We are conscious primarily of our self-sensing and of our feelings; and not with the objective world. What man knows of his environment is all pure deduction from his own conscious states, particularly deductions from the feelings attending sensations. All these deductions serve no other purpose than that of the explanation of these sensations in terms of what we affirm to be their causes. Into that side of human consciousness in which reasoned reflection has no part, the vast contexture of material existence finds entrance in terms of sound, color, taste, cold, heat, resistance, weight, hardness, shape, situation and motion. Whatever one can know of one's environment results when recourse has been taken by one to causation, a concept yielded by pure reason, which causality having been projected into the external world, renders an explanation of sensations possible. Boyle long ago observed that whenever one speaks of experience correcting reason, one speaks improperly; for, he observes, it is reason itself that corrects reason with information supplied by experience. Here it should be noted that man knows many natural phenomena not directly observable through the senses; for example, the chemical constitution of the stars.

The psychological characters of sensation considered without reference to the conditions of its production are hearing, vision, smelling, tasting and touching. All these (we infer) are the effects of external causes or facts. They are so many subjective methods of representing certain processes of the objective world.

Even sensations are a kind of abstractions. By abstractions are meant a singling out, and isolating, a separation of sense impressions, so that they can be held for thought. Our eyes, for example, abstracts certain ether vibrations called light and transforms them into vision. The ears abstract only certain air vibrations and we transform them into sounds. The muscular sense abstracts resistance and we transform this into an idea of corporeality. The skin abstracts temperatures yielding elements for our notions of heat and cold. So is it with all other sensations. They abstract certain features of reality, or facts, and impress us.

There is a firmly rooted muscular sense of rest, uneasiness and of exertion. Various muscular efforts occurring in the head and face have become associated with definite emotions. The labial nasal, and ocular external coverings are muscles of expression. Certainly the vocal muscles give the same kind of an expression, not visible but audible. (Consult T. H. Evans, on 'Some Curious Psychosensory Relationships').

There are no such things as illusions of sense. What is illusory is only an inference to which the feeling elements give rise in sensation. The sensation and its feeling are real psychic events; and it is indeed only by some

reality not merely sensible that even dreams can be condemned. What is illusory is manifest only in misinterpretation of certain experiences.

Vision, hearing, taste, smell and touch depend upon certain stimulations from without;—mechanical (touch), molecular (taste and smell), physical (sight and hearing), and muscular (muscular sensation). At times the required stimulation may be effected within the nervous system. The cerebral processes by which vision (for example) is produced may not only be started in the brain itself, but when so started may result in those identical interpretations which normally accompany the process when set at work by stimuli from the external world.

According to Romanes there is a constant ratio between the amount of agitation produced in a sensory nerve and the intensity of the corresponding sensation. Weber states that if sensations are to increase in intensity by equal amounts the stimulus must increase by relatively equal amounts. His law is that the perceptible increment of sensation is proportional to the quantity of irritation. More precisely: In most cases the quantity of sensation is proportional to the logarithm of the quantity of irritation. Further researches in this direction were undertaken by Fechner, Volkman and Appel; and to their works the students of the subject may be recommended. It is entirely true that we do not experience sensation in the sense-organs. We feel the state of our nerves. The brain itself is the seat of all sensation.

Taste, smell, sight and hearing are operative because of special organs connected by special nerves with the brain. As to touch, while there are special organs, it is an unsettled question whether tactile sensations are conveyed by special nerves or by the ordinary sensory nerves of the skin. The organs of sense depend upon the alertness of the brain for efficiency. It is in fact the brain that sees, hears, etc. As sight, hearing and touch seem to be most concerned with the wants of the intellect, they are sometimes spoken of as the intellectual senses; while taste and smell, being intimately connected with nutrition, are known as the corporeal senses.

Cultivation of the senses, especially if begun in early life, will develop their usefulness. It produces the accurate hearing of the musician, the keen eyesight of the pilot, engineer and expert microscopist, and the accurate touch of the blind. But training may be carried to such an extent as to make these senses sources of misery. Certain persons are painfully conscious of the slightest discord; others almost instantaneously detect, with a feeling of disgust, the inharmonious blending of tints which, to the average person, are all in harmony; still others are made uncomfortable by an odor perceptible to no one but themselves. All the senses become accustomed to continued impressions, so that they no longer perceive their existence. This condition may prove a source of danger, for one may, for example, become habituated to harmful odors. Sense-education of the feeble-minded, as accomplished by Seguin and his wife, by "constant, assiduous, philosophical training," is a noteworthy achievement. It seems to be a rule, with but few exceptions, that when one sense is lost or seriously impaired nature sharpens some other.

Touch, or tactile sensibility, enables us to appreciate by actual contact, the size, form and consistency of objects and the character of their surface. It is most sensitive in the margin of the lips, tip of the tongue, palms of the hands, and under surfaces of the fingers. Some writers speak of «general sensibility» as one of the senses, and include under this term, touch, muscular sense or the sense of pressure, sense of temperature, etc. The organs of touch are end-bulbs and tactile corpuscles. See Muscle-Sensation.

Taste enables us to discover and recognize flavors. This sense resides in the tongue, soft palate, uvula, pillars of the fauces, tonsils and the upper part of the pharynx. The organs of taste are taste-bulbs and various papillæ. The nerves of taste are the gustatory branch of the fifth pair of cranial nerves and the lingual branch of the glosso-pharyngeal nerve. Only those substances can be tasted which are dissolved, and at the same time the mucous membrane of the mouth must be moist.

It is said that the German physiologist Valentin could detect a 100,000th solution of quinine. What we know of the different tastes are complex experiences made up of odors, motor experiences, pressure and pain sensations, visual elements and a far more limited number of taste elements than we suppose. Their number seems to be four: sweet, salt, sour, bitter. Of the physical stimuli of taste sensations we know even less than of the indefinite localized physiological organs of taste. Chemically different substances may even arouse the same sensational response; for example, both sugar and acetate of lead yield a «sweet» taste. Only one statement may be hazarded; namely, that the taste stimulus is always in a liquid form. Taste sensations and their brain area (little known) all involve attention, discrimination, judgment, and so on. The tongue tastes. It also feels. Aerated water is «felt»; alum «draws» the tongue.

The most satisfactory classification of smells as we meet them in nature is that adopted from Linnæus by the Dutch physiologist, Zwaardemaker. It recognizes the following classes: (a) Etheral smells, including all fruit odors; (b) aromatic smells, like those of camphor, spices, lemon, rose; (c) fragrant smells, like those of flowers; (d) ambrosiac smells, like those of musk; (e) alliaceous smells, like those of garlic, assafœtida or fish; (f) empyreumatic smells, like those of tobacco and toast; (g) virulent smells, like that of opium; (h) nauseating smells, like that from decaying animal matter.

Many smells are of course like tastes obviously complex experiences containing elements of taste, touch and vision as well as sensations of smell. The «pungency» of such smells as that of ammonia is a «touch» quality. Smell stimulus is gaseous, not liquid, and the property of stimulating the end-organs of smell is a function of the physical molecule, not of the atom, since most of the chemical elements are odorless.

Smell is the sense by which odors are perceived. The olfactory nerve is, like the optic nerve, a prolongation of the cerebrum. The olfactory bulb is at the anterior extremity of the

olfactory nerve (more strictly the olfactory tract), of which it is an enlargement, and the development of the bulb bears direct relation to the acuteness of smell. In some animals, in which smell is very acute, the bulb is of such size that it is called the olfactory lobe. In man the impressions of this sense often need to be confirmed through other senses. Odors, to be recognized, must be presented in a gaseous or vaporous form. Dryness of the mucous membrane of the nose and excessive secretion blunt the sense of smell. Some persons are so susceptible to odors and emanations that the smell of certain substances, as of roses, new-mown hay, etc., or of certain powdered drugs, may excite in them an inflammation of the nasal passages. Hay fever (q.v.) is one form of such inflammation. There is an intimate relation between smell and taste. Delicate flavors are not appreciated when the nose is obstructed, as by catarrh, etc., or in cases of anosmia (q.v.), loss of the sense of smell. Smell influences the respiratory process, and the breathing of a fine odor increases the amplitude of the respiratory movements. The sense of smell may be highly developed, especially where there is deficiency in other senses. By it certain blind and deaf persons are able to recognize anyone with whom they have previously come in contact. This delicate sense is impaired by oversecretion of the nasal mucous membrane (catarrh), by its dryness or its frequent irritation, and may be destroyed by disease or injury.

Sight is the faculty whereby we receive impression of light, movement, form, size, shades of color, and the manifold beauties of nature and art. The organ of sight is the eye, the nerve of sight, the optic nerve. Necessary also to proper vision are the eyebrow, eyelid, eyelashes, lachrymal and Meibomian glands, tear-passages, and certain muscles. Clear vision depends on the focusing rays of light through clear media upon the retina, and the conveyance of impressions so brought to the cerebrum by means of the optic nerves. Defects in vision are color-blindness, myopia, presbyopia, hypermetropia, astigmatism, etc.

Hearing is a sense whose organ is divided into three parts, external, middle and internal. The latter is essential, the others are accessory. Hearing is effected by means of impressions made by the vibrations of elastic bodies (ordinarily the atmosphere). Impressions of sound-waves are conveyed through the complex apparatus of hearing to the auditory nerves, and through them to the brain. Any interference with the delicate mechanism of the auditory apparatus, as by inflammation or injuries, blunts the sense of hearing. See ANATOMY, COMPARATIVE; NOSE; NOSE AND THROAT; SALIVARY GLANDS.

SENSITIVE PLANT, or **HUMBLE PLANT,** an herb (*Mimosa pudica*) of the family *Mimosaceæ*, a native of tropical America. It is an erect spiny or hairy plant with long-petioled pinnate leaves and numerous purplish flowers in roundish heads, followed by spiny, jointed pods. It is naturalized in many warm countries, and is cultivated as a curiosity in greenhouses and as a summer annual in gardens. The seeds are sown in early spring in any good garden soil and given ordinary care. The plants are chiefly interesting because of the movements of the leaves when touched. If only lightly touched the leaflets close in pairs, but if more roughly the petioles become depressed. Young foliage responds more quickly, the movement usually occurring within one second after contact. In a few minutes the leaves gradually resume their former expanded position, the time required depending upon the age of the foliage, the warmth of the atmosphere, etc. At night the plants "go to sleep," that is, the leaves become depressed as after contact. Other species of *Mimosa*, especially *M. sensitiva*, a semi-climber, are also somewhat sensitive to touch.

SENSORY AREA, a portion of the brain in which the terminals of the sensory nerve-filaments finally end, constituting the cerebral centres of sensation. The location of the general sensory area is by no means definitely known. There are a number of sensory areas: thus the area for the sensations of sound is located in the superior temporal convolutions of the brain, and destruction of this area does not prevent the patient from hearing save when both auditory centres are destroyed, but does prevent him from the intellectual appreciation of what is heard. The sensory area for sight is located in the occipital region; for smell in the brain-base. The general feeling sense-area, however, the so-called sensory centre in the brain, is thought to lie below the motor area, somewhat overlapping it. It will probably be many years before the exact limits of the various areas in which the different sensory axones terminate are known. When that time does come, however, the student of the diseases of the mind will be in a much better position to understand the different variations in personality as shown in diseases of certain areas. Consult Flechsig, 'Gehirn und Seele'; Barker, 'The Nervous System.'

SENTENCE, a combination of words so arranged as to express a complete thought. A sentence is, therefore, the unit of thought expression and as such it determines the construction of words in accordance with their relationship to one another and to the sentence itself. Sentences have been classified in various ways. According to grammatical form, they are simple, compound and complex; agreeable to rhetorical construction they are classed as periodic, loose and balanced. A simple sentence contains but one subject and one predicate, and sometimes one or the other of these two essential parts may not be expressed; but in this case it is necessary that it should be understood. The suppression of the subject pronoun is very common in some languages, notably Spanish. A compound sentence contains two or more principal clauses; example, "The way was long; the wind was cold; the minstrel was infirm and old." A complex sentence must contain but one principal clause and one or more subordinate clauses: "The stag at eve had drunk his fill where danced the moon on Mona's Rill." A periodic sentence is so constructed as to hold the thought in suspense until its close: "Having come to the town early in the morning and having wandered about it all day, it was only in the evening that he went to pay the expected visit to his friend." A loose sentence, on the contrary, may be terminated in two or more places, each termination making complete

sense: «In the evening he paid the expected visit to his friend (after having come to the place early in the morning) and wandered about it all day.» A balanced sentence consists of two parts similar in so far as their form is concerned, but frequently expressing a contrast: «She was an ornament to the society in which she moved; he was a disgrace to the mother who bore him.» Sentences are also classified, according to their use, into declarative, interrogative, imperative and exclamatory. Most sentences are declarative, because a declarative sentence asserts something as a fact. «This road is long,» «This road is not long,» «This road may be long.» These are declarative sentences because each affirms something. One affirms something that is positive, another affirms something that is negative, while the third affirms a doubt or a possibility of doubt in the mind of the speaker. An interrogative sentence, as its name implies, asks a question; an imperative sentence gives a command; and an exclamatory sentence makes a statement under the influence of strong feeling (hence in the form of an exclamation).

Parts of a Sentence.—A sentence may contain subject, predicate, complement, object and various modifiers. In general, in English, the subject and object must be expressed in an imperative sentence, when the pronoun subject is generally suppressed. The complement is used to express the completion of a verbal idea which the verb does not, of itself, complete: «This boy is already a *Man*.» The sentence may have the same kinds of modifiers as the individual words. A subject or object, being a noun or the equivalent thereof, takes adjective modifiers; a verb admits adverbial modifiers; while a noun phrase may serve as the subject or object of a sentence, and as such may take an adjective modifier. Appositional nouns or noun phrases may also be used to modify, through the fact of their apposition, other nouns or noun phrases. Sentences are also sometimes classified as balanced or non-balanced. A balanced sentence has the words and phrases of one part so arranged that they correspond in position and form to those of another part: «Wherever a few great minds have made a stand against violence and fraud, there has been her spirit in the midst of them, inspiring, encouraging, consoling; by the lonely lamp of Erasmus; in the restless bed of Pascal; on the tribune of Mirabeau.» A sentence should have clearness, force and unity. Of these three qualities unity is absolutely necessary for a perfect sentence. In other words a sentence should be a unit in substance and expression. (See RHETORIC). Consult Bloomfield, L., 'Introduction to the Study of Language' (New York 1914); Bosanquet, 'Logic' (London 1911); Tanner, W. M., 'Composition and Rhetoric' (N. Y. 1925); Foerster and Steadman, 'Sentences and Thinking'; Stratton and Woods, 'Good English' (1926).

SENTENCE, *in law,* is a judgment pronounced by the court or judge on a criminal, being the final determination of the court through a judicial decision, publicly and officially declared in a criminal prosecution. It is not the discretionary act of the court, but the judgment of the law, which it is the ministerial duty of the court to pronounce.

SENTIMENTAL JOURNEY, A. 'A Sentimental Journey Through France and Italy,' by the Rev. Laurence Sterne (1713–68), was the result of a seven months' trip that the author took for his health in 1765–66. On his return he completed 'Tristram Shandy' and, though delayed by serious illness, had written two books of 'A Sentimental Journey' by December 1767. These were published on 29 Feb. 1768, and added greatly to the reputation acquired through the former novel. Sterne's death, on March 18, left the book unfinished. What we have is a small volume usually regarded as one of the most original and choice books in English literature, though not of the highest quality. In France its reputation has been even greater than in England.

The book is essentially a more detailed and expanded form of the idea of the seventh volume of 'Tristram Shandy,' written while Sterne was in France in 1762–63, with his wife and daughter. Some of the characters and episodes are the same, as that of the mad girl Maria, but the book is composed from a more definite and special point of view; it was «designed to aid us to love the world and our fellow creatures better than we do.»

WILLIAM T. BREWSTER,
Professor of English, Columbia University.

SENTIMENTAL TOMMY, a novel by J. M. Barrie, published in 1896. It details the life and development of a young writer and is taken to contain considerable autobiographic material. Its sequel is 'Tommy and Grizel' (1900).

SENUSSI, or **SENUSSITES,** an Arab sect or order, founded by Mohammed Ion Ali el Senussi (1791–1851). Influenced by Wahabism, the strict or orthodox sect of Arabian Mohammedism, he organized in 1837 a brotherhood for the purification and simplification of the Faith. Under his influence and that of his son, Sidi el Mahdi, the order spread rapidly, having its strength chiefly in Tripoli and other regions of northern Africa. This secret and aristocratic order had by 1910 over 100 centres and a large and aggressive membership. Sidi el Mahdi died in 1902, and was succeeded by his son, Sidi Ahmed el Sherif. The Senussi aided Turkey in the Italo-Turkish War for the possession of Tripoli in 1911, and at the outbreak of the World War, under German and Turkish influence, they took the side of the Central Powers. Late in 1915 Sidi led a large force of Senussi and Bedouins against Egypt. This attack was repulsed in December, but only after hard fighting by English and South African forces. Other attempts were also checked, and the Senussi suffered a severe defeat at Barrani in January 1916. Later in the same year Great Britain and Italy arranged for a more effective government of the disturbed area, and there were no further serious disturbances. After the war the Senussi acknowledged the sovereignty of Italy over Tripoli. See WAR, EUROPEAN–TURKISH CAMPAIGN.

SEOUL, SÖUL, KEIJO-FU or **HANYANG,** Korea, the capital of the country, on the river Han, about 70 miles by water from its mouth in the Yellow Sea, and 25 miles by rail from Chemulpo, its seaport. The city

proper is a short distance from the river, in a basin partly surrounded by heights, and enclosed by a wall. The former royal palace is the chief edifice, and with its grounds occupies over 500 acres enclosed by a lofty wall. Seoul is the seat of various foreign embassies; a Roman Catholic cathedral and a Confucian temple are other noteworthy buildings. Silk, paper, tobacco, mats, fans and similar commodities are the principal products of native industry. There are schools for the teaching of Japanese, French, Chinese, Korean, Russian and English, and an American Mission School, which is subsidized. Three Korean and two Japanese daily newspapers are published in Seoul, which is connected with all the ports of Korea and with the outer world by telegraph. Under Japanese rule considerable advance has been made. Electric lighting and electric street railways have been introduced, and there is railway communication with Chemulpo, Wiju and Fusan. Pop. 404,202, including 113,321 Japanese.

SEPARATE ESTATE. See HUSBAND AND WIFE.

SEPARATIST SOCIETY OF ZOAR. See ZOAR, SEPARATIST SOCIETY OF.

SEPARATION. See HUSBAND AND WIFE.

SEPARATISTS, in Church history, (1) Those who in the reign of Queen Mary of England refused to conform to the public services of the Roman Catholic Church. Among them was Mr. Rose, who was apprehended with 30 of his congregation while celebrating the Lord's Supper in Bow-church Yard, London. Another well-known Separatist was Mr. Rough of Islington, who with several others was burned at the stake by order of Bishop Bonner. (2) In Ireland the Separatists were numerous, consisting chiefly of the Walkerites, founded by the Rev. John Walker, who seceded from the Established Church of Ireland and founded a small church in Dublin, with the doctrines of the Sandemanians as their creed. Other Irish Separatists were Rev. Mr. Kelly and his adherents who left the Established Church and formed an individual and independent Sandemanian communion. The Darbyites of Ireland were Separatistic Millenarians from whom sprang the Plymouth Brethren. (3) The German Separatists seceded from the Lutheran Church in the 18th century and founded a Pietist sect in Würtemberg. Persecution drove them to emigration and they settled under George Rapp (q.v.) in Pennsylvania, where they founded the Harmony Society, calling themselves Rappists. Those who remained in Germany established themselves at Kornthal, under the name of Kornthalites. All who in Germany refused to conform to the German Evangelical Union, founded by Frederick William III of Prussia, were also known as Separatists. (4) The name was taken by some of the early Puritans such as the Traskites (q.v.). They were subsequently represented by the Quakers. Among the most important sects which have assumed this name are the Separatists of Zoar, a village of Tuscarawas County, Ohio. Their constitution is strictly communistic; they refuse to serve as soldiers; consider celibacy a higher life than marriage; reject all religious ceremonies, while maintaining the cardinal doctrines of Christianity. In 1898 it was decided to distribute all the property among the members, then numbering about 225, and this abolished the communistic features of the society. The municipal incorporation of the Society of Zoar, however, remained intact, and the community still continues to exist, but without many of its distinguishing characteristics.

SEPIA. See CUTTLEFISH.

SEPIOLITE, a compact, clay-like mineral of smooth feel, hardness 2 to 2.5, specific gravity 2. Owing to its porous nature it floats on water when dry. Color white or slightly tinted gray, yellow, red, or green. It is a hydrous silicate of magnesium, $H_4Mg_2Si_3O_{10}$. Extensive beds in Spain are utilized as a building stone. The mineral from Morocco is used in Algeria as a substitute for soap. It occurs as a secondary mineral derived from magnesite in the plains of Asia Minor, in alluvial deposits. The mineral from these deposits, popularly known as "Meerschaum" (q.v.), is used in the manufacture of tobacco pipes.

SEPOYS, sē'poiz, or sẹ-poiz', the name given in India to the forces composed of natives, disciplined after the European manner. The French were the first to see that the transportation of troops from Europe to their Indian colonies would be too expensive and that Europeans would perish in great numbers by the exposure at sea and in the climate of India. They therefore took Hindus into pay and the English adopted the same policy. In 1937 the total strength of the native army in India was 159,200, and that of the European was 57,045 The Sepoys are hardy and capable of enduring much, and very temperate in their food.

SEPPUKU. See JAPAN—*The Samurai-Bushiclo.*

SEPT-FOIL, an ornament or figure which has seven leaves or lobes; a church ornament composed of seven equal segments of a circle used to symbolize the number of the sacraments, gifts of the Holy Ghost, etc.

SEPTEMBER, the ninth month of the modern year, but the seventh of the old Roman year, which began in March. It has always contained 30 days. See CALENDAR.

SEPTEMBRISTS, in French history, the name given to the agents in the massacre which took place in Paris on 2 and 3 Sept. 1792, during the French Revolution. The numbers that perished in this massacre have been variously given; but the term has become proverbial throughout Europe for all that is bloodthirsty and malignant in human nature.

SEPTENNATE ACT, The. In the German Parliamentary elections of 1887 the struggle centred around the septennate, or seven-year army period. On 14 January the emperor dissolved the Reichstag and ordered new elections to take place. The government had proposed the addition of 40,000 men to the standing army, and sanctioned the maintenance of the present military force for another septennate. No previous army grant had been for more than two years. Prince Bismarck favored the measure. The emperor said, "The septennate means peace. Reject it and there will be war." But the delegates voted the supplies for three years only, and the chancellor, by a decree from the throne, dissolved the house. The government secured a majority

in the general election, Feb. 1, 1887, and on March 11, the new Reichstag passed the septennate bill.

SEPTUAGESIMA SUNDAY the third Sunday before Lent, so called from its being about 70 days before Easter (*septuagesimus* 70th).

SEPTUAGINT, sĕp'tû-à-jĭnt, the oldest Greek version of the Old Testament. It is also called the Alexandrine version, or the Version of the Seventy, or, simply, the LXX (=70). The legend of its origin, as given in the *Epistle of Aristeas* (c.100 B.C.), is that Ptolemy II Philadelphus, king of Egypt (285–246 B.C.), requested the Jewish high priest in Jerusalem to send 70 (or 72, i.e., 6 from each of the 12 tribes) scholars to Alexandria to translate the sacred Hebrew law into Greek. Their task was accomplished with miraculous speed and was miraculously accurate.

The historical facts underlying the legend are probably as follows: The version was made in Alexandria, beginning in the reign of Ptolemy II, for the use of the large numbers of Alexandrian Jews who were no longer familiar with Hebrew. The first portion to be translated was the Pentateuch; the Prophets followed, and eventually the Writings (i.e., all the rest). The latest parts were probably translated in the 1st century B.C. Certain books not found in the Palestinian or Hebrew canon, such as the Wisdom of Solomon, were added (the so-called Apocrypha), perhaps as late as the beginning of the Christian era.

The varieties of style show that there must have been several translators, though how many it is impossible to ascertain. The language of the LXX is the Hellenistic Greek of Alexandria, based upon the Attic dialect. The most accurate work of translation is found in the Pentateuch, and next to it the Proverbs. The translation of the Psalms and the Prophets is paraphrastic; Jeremiah is well done, but Daniel is so bad that editors usually give the text of Theodotion (fl. 185 A.D.) in its place. It is thought that the Hebrew upon which the LXX was based was written in square characters, unpointed (i.e., without vowels), without separation of words, and with many abbreviations. It once was supposed that the disagreements between the Greek and Hebrew texts could be explained by assuming that the LXX translated the Samaritan Pentateuch. But this is most unlikely; a more probable theory is that the ancient Hebrew text differed somewhat from the later (Masoretic) and that the Greek text itself was changed slightly by copyists during the period prior to our oldest manuscripts.

The LXX is the original of most of the ancient versions of the Old Testament. Even where (as in the case of the Syriac) the translation was made directly from the Hebrew, the LXX has influenced the later form of the text, sometimes producing later revisions or recensions of it. It was the Bible of the earliest Greek-speaking church, to which the Greek New Testament was added; thus it has remained the standard text of the Greek Orthodox Church ever since. Of 350 direct Old Testament quotations in the New Testament, scarcely 50 disagree materially with the LXX. Though used by Philo (25 B.C.?–?45 A.D.) and Josephus (37?–100 A.D.) and probably by Greek-speaking Jews in general for two centuries or more, it was abandoned by the Jews after it had been adopted by the Christians and had received a Christian interpretation. In its place far more literal translations were provided, but even these soon were abandoned; to this day the synagogue services use the Hebrew Old Testament.

As Origen (185?–?254 A.D.), whose *Hexapla* is the first critical edition of the Alexandrian Greek Bible, was the first to see, the Septuagint is of very great value to the textual critic, as it testifies to the state of the text many centuries prior to the standard Hebrew of the medieval manuscripts. (This text has not altered very greatly, as the Dead Sea scrolls of Isaiah found in 1947 seem to show.) Even the mistakes of the LXX are useful, as showing what Hebrew words were misunderstood.

The leading manuscripts are the *Codex Vaticanus* in Rome, *Codex Alexandrinus* and *Codex Sinaiticus* in the British Museum, and the Washington and Chester Beatty fragments.

The chief modern editions are: the smaller Cambridge one, edited by H. B. Swete in three volumes (3d-4th ed., 1907–1912); the larger Cambridge, edited by A. E. Brooke, N. McLean, and H. St. J. Thackeray, of which nine parts have appeared (1906–1950); and the two-volume Stuttgart, edited by Alfred Rahlfs (1935).

E. Hatch and H. A. Redpath have compiled a complete *Concordance to the Septuagint* (Oxford 1897).

Bibliography.—Swete, H. B., *Introduction to the Old Testament in Greek,* 2d ed. (Cambridge 1914); Ottley, R. R., *A Handbook to the Septuagint* (London 1920); Thackeray, H. St. J., *The Septuagint and Jewish Worship* (Oxford 1921); Pfeiffer, R. H., *Introduction to the Old Testament,* rev. ed. (New York 1948); Hadas, Moses, ed., *Aristeas to Philocrates* (New York 1951).

FREDERICK C. GRANT,
Union Theological Seminary.

SEPULCHRAL ARCHITECTURE, a form of art whose purpose is to give beauty or magnificence to tombs or to buildings used only for purposes of sepulture. No particular style of architecture belongs strictly to sepulchral structures. Some styles, it may be said, lend themselves more readily than others, at least for splendor of effect. Such for instance is the Gothic, in which style many beautiful specimens exist, particularly in the cathedrals and abbeys of England. In this style is the sepulchral church of Brou at Bourg-en-Bresse. A distinction is here to be noted between the practice of ancient and mediaeval times. In the case of the former the tomb was a building, large or small, apart from structures devoted to the uses of religious worship. The pyramids of Egypt were the most imposing of all human structures; the mausoleum at Halicarnassus, one of the wonders of the ancient world. The buildings erected in memory of the Mohammedan rulers in northern India as well as the Taj Mahal are to be taken with the foregoing as not strictly tombs, but as belonging to the domain of sepulchral architecture. Of all the Aryan peoples the Romans were conspicuous for their imposing tombs, specimens of which exist in the remains of the tomb of Caecilia Metella and the Mole of Hadrian, now called the castle of St. Angelo at Rome. Belonging to the period of the Renaissance are the tombs of the Medici, erected by Michelangelo, though of these the sculptural features are more important than the architectural. One of the most perfect specimens of this period is the tomb

of Loys de Brézé, erected by his wife Diane de Poitiers in the cathedral of Rouen, and attributed to Jean Goujon and Jean Cousin. In America the most notable specimen is the tomb of General Grant, a structure resembling in general form the tomb of Caecilia Metella. See also BURYING-PLACES; MONUMENTS; SCULPTURE; TOMB.

SEQUESTRATION, sē-kwĕs-trā′shŭn, *in law,* the act of taking possession of property by legal authority, as to satisfy creditors, for the use of the state, etc.; also, an equitable writ, directed to a sheriff or a number of commissioners ordering them to enter upon the estate of the defendant and to take the rents, issues and profits and to keep or pay out the same as the court shall direct. It is also used by chancery courts to force compliance with their decrees or orders.

SEQUIN, sē′kwĭn, an Italian and Turkish gold coin. It was first struck at Venice about the end of the 13th century, and afterward in all the other Italian cities, and from the Levant was introduced into Turkey. The Tuscan sequin is worth $2.30, the Turkish from $1.10 to $1.75.

SEQUOIA, sē-kwoi′ȧ, a genus of Coniferae, included in the subfamily Taxodioidae, of which the other genus is the *Taxodium* or deciduous cypress. The Sequoia genus (named in honor of the Cherokee chief Sequo-yah, who invented the alphabet of that tribe), was for a time known as *Taxodium* or *Wellingtonia;* it comprised two species, *S. sempervirens,* the redwood, and *S. gigantea,* the "big-tree," both natives of California. The genus was once widely distributed, as fossil remains testify, and the petrified forest in Arizona is stated to be composed of species of sequoia. The flowers of the sequoias are monoecious and are borne in scaly inflorescences as terminal or axillary shoots in such great profusion, that the pollen covers the ground beneath the trees during their winter blooming. The pistillate flowers mature into a fruit, or oval cone, having persistent woody scales, broadened at their outside ends into a rhomboidal flat top, very much wrinkled, and with a slightly prickle-tipped apex. Their scales are slightly separated to allow the many brown, compressed seeds to escape and then spin away on their lateral wings. The leaves are acute, compressed and keeled, decurrent on the stem, alternate and inserted in spirals, very scale-like on the branchlets, but on older branches linear and spreading.

The redwood, which was the first *Sequoia* discovered, is the more common species, and grows along the Pacific Coast just so far inland as the sea-fogs can go. It is a very straight, handsome tree, with columnar trunk, and spreading branches and branchlets, and reaches in some instances as great a height as the other and more famous species.

Sequoia gigantea, the "big-tree of California," is more rare. It is found in seventy-odd groves, forming an uninterrupted "belt" extending for 250 miles on the western slope of the Sierra Nevada Mountains, and nowhere else in the world. It grows at elevations of 3,500 to 8,400 feet. This has suggested that possible lower growths were destroyed by glacial action. The Calaveras grove near the northern extremity of this series is the most picturesque and important group of big trees, and was first discovered by J. Bidwell in 1841. These famous trees are the most massive of any in the world, but are not the tallest, being surpassed by the Eucalyptus trees of Australia. They are practically exempt from disease, and, if they were not injured by fire and by man, would have apparently an almost endless life. Some of them are judged, by the number of annual rings, to have been thousands of years old. Fully grown trees average a height of 275 feet, and a diameter of 25 feet. One of the most gigantic, cut down, with great difficulty, in 1853, was 302 feet in height, 96 feet in circumference, and after the bark was removed (which was itself nearly 18 inches thick, the diameter of the solid wood in the stump was 25 feet, 6 feet from the ground. This stump was used as a dancing floor, holding 40 or more persons. Others have been estimated as between 350 and 400 feet high. A section of one of these great trees has been placed in the Museum of Natural History in New York, and another in South Kensington, England.

The younger sequoias are very graceful, and charming in their dark blue-green foliage, being often grown in English and European parks. They have a straight, tapering stem from which the branches spring to form a narrow spire-like pyramid. After a few hundred years they begin to lose their branches, and become dome-like. Ultimately they become our picturesque trees, with a great trunk enlarged at the base, and strongly buttressed, fluted with low broad ridges, and covered with cinnamon brown bark (purple-tinted in the shadow) which follows the contour of the lobed trunk, and is deeply, longitudinally furrowed, and separated into fibrous scales on the ridges. This tapering shaft is naked for 100 or more feet, when great branches, eccentric in development, join in constructing the narrow, but massive domes which stand out above the other tall trees of the Sierras, and break into delicate but dense spray of much divided pendulous branchlets, blue-green when young but developing a bronzy tint when mature.

The big trees, while standing, have served as shelter for men and cattle, and are a constant attraction for tourists, the largest being known by name. One, the Wawona, in the Mariposa grove, has a portal cut through its base, which allows the passage of vehicles. The oldest tree whose age has been determined with some accuracy, having been felled for lumber, lived for 3,148 years, according to W. L. Jepson, the botanist. But fossil remains of other sequoia species, found elsewhere in the United States, Manchuria, Australia, Greenland and Europe, prove that the genus flourished as far back as the Tertiary and even in the Cretaceous period.

Although thousands of the big trees have been destroyed by lumbermen, many fine groves are preserved in the Sequoia, General Grant, and Yosemite national parks. See also REDWOOD OF CALIFORNIA.

SEQUOIA NATIONAL PARK, a national park in middle eastern California, established in 1890. Its chief purpose is the protection of the great sequoia trees, of which there are several hundred, all over ten feet in diameter. Situated about 55 miles east-southeast of Fresno, it has an area of 601.7 square miles. Giant Forest is the best known of its 35 sequoia groves. On its eastern boundary is Mount Whitney (14,495 feet).

SEQUOYA, sē-kwoi'à, or **SEQUOYAH,** sē-kwō'yà, Cherokee Indian scholar: b. Taskigi, Tenn., about 1770; d. near San Fernandino, Northern Mexico, August 1843. At maturity he assumed the name of George Guess, an American trader whom he believed to be his father. He was a silversmith among the Cherokees in Georgia, where, between 1809 and 1821 he invented a system by which, employing 85 characters, every sound in the Cherokee language could be reduced to writing. This syllabary, which was approved by the Cherokee general council in 1821, enabled thousands of tribesmen to read and write. It was adopted by the missionaries, and was used in printing the *Cherokee Phoenix and Indian Advocate,* a weekly newspaper first published in 1828. The success of his system induced him in 1823 to carry the new learning to the western tribes in Arkansas. His name was perpetuated in the tree Sequoia and in Sequoia National Park (qq.v.). Consult Sweetser, Kate D., *The Book of Indian Braves* (1913).

SERAC, a term applied to the ridges or ice pinnacles between closely spaced glacial crevasses. See Glacier.

SERAFIN, sā'rä-fēn', **Tullio,** Italian operatic conductor: b. Rottanova di Cavarzere, Venice, Dec. 8, 1878. He graduated at the Milan Conservatory, and made his debut as conductor with *Aïda,* in Ferrara. In 1909 he succeeded Arturo Toscanini (q.v.) as conductor of La Scala Opera House, Milan. He conducted at the Metropolitan Opera House, New York City, in 1924, and he also made frequent appearances as guest-conductor in Paris, London, Rome, and Buenos Aires.

SERAGLIO, sĕ-räl'yō, Istanbul, Turkey, the former imperial palace of the Osmanli sultans, occupying the extreme eastern part of the city proper, at the entrance of the Bosporus. It stands on the site of ancient Byzantium and is of great historic interest. The existing buildings date from the time of Mahmoud II, and chiefly occupy the summit of a hill, which is surrounded by fine gardens, the whole being enclosed by ruinous walls, partly of mediaeval origin. The entrance is on the west, near the Museum of Holy Wisdom, by the Imperial Gate (*Babi Humayum,* the "Sublime Porte"), which leads into a court lined by the mint, the old church of Saint Irene (later an armory, with many interesting objects), and a museum of antiquities (also of some interest). Another gate, the *Orta Kapousi,* leads from this court into an inner one, which is surrounded by arcades and the former kitchens of the sultan, his wives, and officials. The main part of the seraglio is then reached through the *Babi Saadet,* or Gate of Felicity, formerly guarded by eunuchs. Here is the Hall of the Divan, where ambassadors were formerly received, councils held, and justice administered; the treasury, with beautiful and valuable collections; and the harem, where the sultan's wives were housed. There are also mosques and other buildings within the enclosure. From the time of Mahmoud II, this palace was not regularly occupied by the sultans, and it therefore lost much of its former magnificence and interest. The word seraglio in Western parlance has come to denote a harem, or place for the seculsion of concubines.

SERAING, sē-răn', Belgium, a town in the province of Liège, three miles southwest of the city of that name, on the Meuse river. The castle, formerly the residence of the prince-bishops of Liège, was converted into the headquarters of one of Europe's largest ironworks in 1816. Coal is mined in the neighborhood, and glass is manufactured. The town's resources proved of considerable value to the German invaders during World Wars I and II. Pop. 42,981.

SERAJEVO. See Sarajevo.

SERAMPORE, sĕr-ŭm-pōr', or **SRIRAMPUR,** India, in Bengal, a town on the Hoogly River, 12 miles north of Calcutta, and opposite Barrackpur. It has a school, church, college and library, connected with the Baptist Mission. The principal industry is the manufacture of paper and mats. The town under the name of Frederiksnagar, belonged to Denmark from 1755 until 1845, when it was purchased by the (British) East India Company. Early in the 19th century it was the scene of Baptist missionary activities, and contains the graves of William Ward (q.v.), William Carey (q.v.) and others associated with the work. The town is attractive, and a summer resort for citizens of Calcutta. Pop. 55,339.

SERAO, sā-rä'ô, **Matilda,** Italian novelist: b. Patras, Greece, 1856; d. Naples, July 25, 1927. She was the daughter of an Italian political exile and a Greek mother. She became a schoolmistress at Naples, and her struggles with poverty during this period are related in the introduction to *Leggende Napolitaine* (1881). At the same time she assisted her father in editing his newspaper, and contributed short stories of Neapolitan life to *Il Piccolo* and other local publications. She first attracted attention by *Novelle,* a short story, followed by her first popular novel *Fantasia* (1883). From 1880 to 1886 she lived in Rome interested in literary work with Gabriele D'Annunzio (q.v.), Eduardo Scarfoglio and others, and published *Cuore Inferno* (1881); *Fiordi Passione* (1883); *Piccole Anime* (1883); *La Virtù de Checchina* (1884); *and La Conquista di Roma* (1885). She married Scarfoglio in 1885 and with him founded the short-lived *Il Corriere di Roma;* later returning to Naples, she edited *Il Corriere di Napoli* and subsequently founded *Il Mattino* and *Il Giornio,* which attained large circulations. She actively continued her book production. *Ventre di Napoli* appeared (1885); *Paese di Cuccagna* (1891); *Addio Amore; All 'Erta Sentinella; Castigo; La Ballerina; Suor Giovanna della Croce; Paese di Gesu,* between 1892 and 1902; *Storia di due anime* (1904); *Dopo il perdono* (1906); *I capelli di Sasone; Sterminator Vesevo* (1910); *Desire of Life* (1922); *Ella non Rispose* (1914); *Diario Femminile di Guerra* (1916); *Mors Tua* (1926). Many of her works were translated into English. Her early work was distinguished for the vigor of its realism, acute sensibility, and accurate observation; these traits were developed with clearer insight and deeper psychological analysis in her later works. See La Ballerina; Paese di Cuccagna.

SERAPEUM, the designation of Egyptian temples dedicated to the god Serapis. The Serapeum at Memphis was the most famous. It

was the cemetery of the Apis, and close to the Apeum, where the bull dwelt while in life. Within its precincts also were the dwellings of the priests, and a hospital for the sick, who flocked here to be cured by the dreams vouchsafed them by the god.

SERAPHIM, a plural Hebrew noun which occurs only in one passage of the Bible, Isaiah 6: 2-6, where it denoted certain heavenly creatures of human form but having each six wings, with one pair of which they covered the face, with another pair the feet, and with the third pair did fly. Their station was above the throne of the Most High, and one cried to another, "Holy, holy, holy is the Lord of hosts." The prophet was in terror, conscious of his unworthiness and that he was a "man of unclean lips." Thereupon one of the seraphim, taking from the altar a live coal in his hand, with it touched Isaiah's lips, purifying them and purging his sin. The seraphim are in the later Jewish theology and in Christian angelology classed as the highest of the orders of angels, holding the first place in the first triad of the angelic hierarchy—seraphim, cherubim and thrones.

SERAPION, physician of Alexandria, of the sect of the Empirici, who flourished about the 3d century. He occupied himself almost exclusively with inquiries into the nature of drugs, and was a keen opponent of Hippocrates.

SERAPIS, sĕ-rā'pĭs, or **SARAPIS,** an Egyptian divinity whose worship was introduced into Egypt in the reign of Ptolemy I. It is related by Plutarch and Tacitus that Ptolemy having seen in a dream the image of a god, which he was ordered to remove from the place in which it stood, sent to Sinope, on the suggestion of a traveler named Sosibius, and brought thence a colossal statue, which he sent up to Alexandria. It was declared to represent the god Serapis, affirmed by Manetho to be Pluto or the Jupiter of Sinope. A magnificent temple was built at Alexandria for the reception of the statue of Serapis, and this temple—the Serapeum—was the last hold of the pagans in that city after the introduction of Christianity. Another temple of this god at Memphis, beside the Apis cemetery, was discovered by Mariette in 1850. The Egyptians themselves never acknowledged him in their pantheon, but he was the principal deity in the Greek and Roman towns, and was considered to be either Osiris, Aesculapius, Jupiter or Pluto.

SERBIA, a federal unit of Yugoslavia, located in the heart of the Balkan Peninsula and constituting the east central and most important part of Yugoslavia. From 1878 to 1918 Serbia was an independent kingdom. On the north it is bounded by Hungary and to the east lie Rumania and Bulgaria. On the south its border meets that of Yugoslav Macedonia, then takes a northerly course along Albania until it meets the eastern edge of Montenegro. Following from there the Drina River which separates it from Hercegovina and Bosnia as far as the Sava River, the border finally touches eastern Croatia and the Danube.

Serbia's population on the eve of World War I was 4,800,000, of which 700,000 were Moslems, Albanians, and Turks inhabiting the southern provinces liberated after the Balkan Wars. The remainder of the population was Serbian, belonging to the Serbian Orthodox faith. Before the Balkan Wars the population was 98.4 per cent homogeneous Serb. According to the official census of 1931, the population of Serbia was 5,795,724.

For the geography, topography, and economic development of Serbia, see YUGOSLAVIA.

HISTORY

Concerning the origin of the term "Serb" there are several hypotheses, but until recent times the exact etymology of the word had not been definitely established. One of the theories advanced is that it comes from the Caucasian *ser,* meaning "man," with the plural suffix of *bi* of that language added. The name Serb is mentioned for the first time by the geographer Vibius Sequestrus (6th century A.D.), and the first Serbs appeared in central Europe at the beginning of the 6th century—in Germany (provinces of Magdeburg and Anhalt). The German city of Zerbst (Serbiste in Slav) is a reminder of the early invasion. Serbs in the Balkan Peninsula are mentioned for the first time in 822 by Einhard of Charlemagne's court, but the Byzantine emperor, Constantine Porphyrogenitus, refers to Serbs already being in the Illyric province by the middle of the 7th century.

The Serbs were one of the peoples of the Caucasus and lived on the eastern shores of the Sea of Azov. At the time of the barbarian invasions, they began to move with other Slavs toward the West, a progress that began as early as the 4th century. It has been established that when the Huns invaded Europe in the 5th century, they were accompanied by Slavs. A century later the Slavs had settled in Rumania, and during the 7th century had colonized the Balkan Peninsula by conquest. They proceeded ruthlessly with their colonization, destroying several important cities which had been founded by the Romans—among them being Singidunum (Belgrade), Viminacium (Kostolac on the Danube), Dioclea (Podgorica, now called Titograd, in Montenegro), Salona (Split in Dalmatia). Their democratic, clannish organization was concerned only with the direct interests of their particular tribe or clan; and the tribes themselves had no deeper sense of unity, or consciousness of common interests. This seems to have been the main reason for their anarchic life, and their resultant weakness in spite of numerical strength. It is also the reason why the Slavs have been slow in organizing their own states, and is the evident explanation of the fact that the first Slav states were organized by foreigners.

The Nemanya Dynasty.—Rascia, the first Serb state, was founded in the mountains of southeastern Bosnia and northeastern Hercegovina, and tended, from the 10th century, to expand eastward and southeastward toward the plains of Kosovo and the valleys of the Vardar and Morava. At that time it centered principally around the Raska River, from which it originally took its name. The definite organization of the state was accomplished by Stephen Nemanya (Stevan Nemanja; r. 1168–1196), one of the ablest and most outstanding of the rulers of Serbia, who extended the nucleus of the country into the Morava Valley, and into the Vardar Valley to the south. His son Rastko, later known as St. Sava, was an intelligent and energetic

* Pp. 579-588 deleted. The former Serb, Croat and Slovene State is now Yugoslavia (q.v.).

statesman, and continued the work begun by his father. He founded the independent Serbian Orthodox Church which still bears his name, and his memory is revered by all Serbs.

The Nemanya (Nemanja, q.v.) dynasty ruled during two centuries, producing many powerful kings who from the 14th century on made Serbia the strongest state in the Balkan Peninsula, prepared to take the place of the decadent Byzantine Empire. In 1330 (Battle of Velbuzhd, now Kyustendil), Stephen (Stevan) Uroš III, one of the most famous of the Serbian kings, defeated the Bulgars, driving them out of the Vardar Valley. In 1346, Stephen Dushan or Dušan (Stevan Uroš IV), unlike his predecessors who were crowned kings of Serbia, assumed the title of emperor of the Serbs, Bulgars, Greeks, and Albanians. However, an early death (1355) put an end to his ambitious plans.

The economic and cultural progress of Serbia at this period was above the average European level. Many monasteries of Serbian-Byzantine architectural style (Studenitca, Decani, Gračanica, and others), founded by several kings, bear witness to this highly developed culture of the Serbs. Dushan's code of laws (*Zakonik*), formulated 1349–1354, shows the advanced social structure of the Serbian state.

Under Turkish Rule.—Dushan's successór, Stephen Uroš V, lacked the energy and strength of his father, and the latter's conquests ended by becoming a source of weakness for the state. The Turkish drive toward Europe turned its might toward the Serbs, first defeating them at the Maritsa River in 1371, and then on the Plain of Kosovo in 1389, where the Serbian defenders fought courageously against far superior Turkish forces. In that battle the Serbian prince, Lazar I, was killed, as was also the Turkish sultan, Murad I. Kosovo was not only a battle where crowned heads fell; it marked as well the fall of the independent Serbian state. Serbia continued her precarious independence until 1459, her rulers retreating to the north on the Danube, seeking the protection of the Hungarian kings.

With the downfall of the Serbian state, the nation came under the Turkish yoke where it remained for more than four centuries. It was not until 1804 that the Serbs began their struggle for liberation. During this long Turkish occupation, the Serbian Orthodox Church remained the only national institution not destroyed by the conquerors; it was active in keeping alive the traditions of the old state of the Nemanya and the glorious empire of Dushan, as well as faith in a better future. In the southeastern part of Serbia—Montenegro—the freedom-loving mountaineers retreated to their inaccessible mountains and successfully resisted all Turkish attempts at conquest.

A slow decline of the Turkish Empire began in the 17th century until, in 1683 the Turks were defeated near Vienna. From then on, they gradually retreated southward toward the Danube and Sava rivers. The Porte (Turkish government), however, was slowly losing control not only of its army, but also of its governors in the distant provinces; more and more these officials resorted to terroristic methods to preserve their conquests. Under these conditions the Serbian people grew desperate, and finally, after several unsuccessful attempts, they started (1804) the great national revolution against the Turks.

The Fight for Independence.—The Serbs were led in this revolt by George Petrović, called Karageorge (Karadjordje or Black George), whose family had emigrated to Serbia from Montenegro in the first part of the 18th century. Karageorge, a man of great courage and ability, had fought the Turks from his earliest youth. He was elected by the people as their leader at the outbreak of the revolt, and after a series of victories at Ivankovac, Mišar, and Belgrade (Beograd), he succeeded in freeing all the pashalik (province) of Belgrade from the Turks. In that same year Russia, which was also involved in a war with Turkey, concluded an alliance with Serbia which drew the attention of Europe to this former Ottoman province. Serbia enjoyed a fair degree of autonomy and was self-governing. In the Treaty of Bucharest with Russia in 1812, the Ottoman Empire recognized the autonomy of Serbia and obligated itself to treat the Serbs with moderation.

Turkey, however, taking advantage of the difficult situation of Russia which was then at war with Napoleon, refused to carry out the obligations of the treaty and moved in force against the Serbs. Karageorge was forced to retreat to Austria in 1813, but the Serbs started a second revolt in 1815, led this time by Miloš Obrenovich (Obrenović). Both revolts had originated in Shumadiya, the heart of Serbia.

If Karageorge is remembered as the greatest Serbian hero, Miloš is considered the most astute of Serbian diplomats. He succeeded in obtaining the autonomy of the country when in March 1826 the Porte signed a convention with Russia at Akkarman, by which Turkey bound herself to carry out within 18 months the provisions of the Treaty of Bucharest of 1812.

Later, in the Treaty of Adrianople (Sept. 14, 1829) with Russia, Turkey solemnly engaged herself to honor without delay her obligations toward Serbia, and also to evacuate her army from six counties belonging to the pashalik of Belgrade.

In 1830 the sultan issued a *hatti-sherif* (a solemn personal letter) guaranteeing Serbia's autonomy, under Russian protection, and recognizing Miloš Obrenovich as hereditary prince of Serbia. In 1833, Turkey finally ceded to Serbia the six counties of the pashalik of Belgrade which she still occupied, and Miloš made a state visit to the sultan in 1835 to pay his respects and to thank him for fulfilling his promises.

Although Miloš was known as an able diplomat, in governing his country he used absolutist methods, which in spite of his successes earned him the hatred of his people. He was finally forced to abdicate in 1839. This popular disfavor extended also to his son Michael who, after a short reign, abdicated in 1842. The People's Assembly (Skulpština) then called Karageorge's son Alexander Karageorgevich back to the throne. Alexander ruled from 1842 to 1858, his reign being marked by considerable improvement in the cultural life of the country and the development of the organization of the state. During his reign Serbia moved a step forward toward full independence, when the Congress of Paris in 1856 confirmed the autonomy of Serbia as being guaranteed by all the great powers and not by Russia alone.

In 1858, Prince Alexander, who was engaged in a conflict with the party of "defenders of the constitution" (Ustavobranitelji), also had to abdicate and leave the country.

The old autocrat Miloš Obrenovich, then living in exile in Rumania, was recalled to the throne of Serbia. His reign was short, however, as he died less than two years afterward.

Michael Obrenovich then reascended the throne (1860). He was a well-educated and liberal-minded prince. At this time Europe was dominated by the policy of nationalities encouraged by Napoleon III. National unification was in progress in Germany as well as in Italy. Fired by these examples, Michael formed ambitious plans for liberating the different nationalities still within the Turkish Empire. He entered into negotiations with the rulers of Greece, Rumania, and the neighboring principality of Montenegro, as well as with Serbian national leaders in Bosnia and Bulgaria, with the view to creating a vast alliance against the Ottoman Empire. He also established friendly relations with the Croat leaders—particularly with Bishop Joseph Georg Strossmayer, hoping to promote closer relations between Serbs and Croats. But his plans did not materialize as he was assassinated on June 10, 1868.

The reign of Michael, marked as it was by many diplomatic successes, proved another step toward the complete liberation of Serbia. The Turks had reserved the right to keep garrisons in Belgrade and several other cities, but by patient diplomatic action, supported by France, Great Britain, and Russia, Michael obtained from the Porte in 1867 the withdrawal of the garrisons from Serbia. The only evidence that Serbia was not as yet a fully independent state was the Turkish flag which continued to fly beside the Serbian flag over the evacuated fortresses.

Michael was succeeded by his nephew Milan during whose reign Serbia engaged in two wars with Turkey (1876 and 1877–1878) for the liberation of the Serbs from the Ottoman Empire. The first of these wars against the Turks was waged unsuccessfully by the Serbians and Montenegrins alone. In the second war the Serbians joined forces with the Russians and succeeded in liberating Niš and substantial territories in the south and southeast of Serbia. But the policy of Russia was to favor Bulgaria at the expense of Serbia in order thus to pave the way for access to the Aegean Sea and the Mediterranean. The Treaty of San Stefano (March 3, 1878) created a Great Bulgaria and deprived Serbia of almost all her military conquests. The Berlin Congress (q.v.) in 1878 nullified the Treaty of San Stefano and established a new status in the Balkans. Serbia was substantially enlarged in the south and southeast; but above all she was now recognized as a fully independent state. On the other hand, the Congress of Berlin decreed that Austria-Hungary occupy the predominantly Serbian provinces of Bosnia and Hercegovina. This occupation led to new troubles in the Balkans and finally became one of the indirect causes of World War I.

Establishment of the Kingdom.—On Feb. 22, 1882, the Serbian Parliament proclaimed Serbia a kingdom and Milan its first king. In 1885, after the unification of Bulgaria with Eastern Rumelia, Milan attacked the Bulgars, fearing they would become the strongest state in the Balkans. In this war he was unsuccessful and later had to face considerable difficulties at home. Finally he was forced to abdicate in 1889 in favor of his son Alexander.

Alexander I. Obrenovich was the most unpopular king in the history of Serbia, and his marriage to Draga Mashin, a commoner widow 10 years his senior, greatly increased his unpopularity. On June 10, 1903, Alexander and Queen Draga were assassinated. With this event the Obrenovich dynasty came to an end.

At Alexander's death, the Serbian Assembly called Peter I Karageorgevich to the throne. He was the son of Alexander Karageorgevich and the grandson of Karageorge himself. Peter had spent most of his life in exile. He had been educated in France and Switzerland where he had been imbued with liberal and democratic ideals. His reign marked the beginning of a new era for Serbia during which the country made considerable progress in all fields of national activity. It developed a parliamentary system and democratic institutions and achieved economic and social progress which might well have served as an example for many other countries. The new Serbia attracted not only her brothers under the Turkish rule, but also the Serbs and Croats in the Austro-Hungarian Empire. Austria-Hungary, afraid of Serbia's progressiveness, tried to arrest it by annexing Bosnia and Hercegovina in 1908, while engaging in an economic war with the Serbs. Two years later she refused to renew the trade agreement with Serbia, forcing the Serbs to seek new markets for their exports. The Serbian government passed through this economic crisis successfully, and directed its efforts toward the creation of a Balkan League (q.v.) for the liberation of the Balkans from the Turks.

The Balkan Wars (1912–1913).—In October 1912, the Balkan League (Serbia, Montenegro, Bulgaria, and Greece) engaged in war against Turkey. The Turkish Army was defeated, and those parts of the Balkans still under Turkish rule were liberated after 500 years. The Serbian Army particularly distinguished itself in a series of victorious battles—Kumanovo, Novi Pazar, Monastir (Bitolj)—and also took a prominent part in the seige and capture of the great Turkish fortress of Adrianople (Edirne). However, the Balkan allies failed to agree on the division of the territory thus liberated from the Turks, and Bulgaria refused to submit the issue to arbitration by the czar of Russia according to the provisions of the Treaty of Alliance between Serbia and Bulgaria. Encouraged by Austria-Hungary, Bulgaria attacked Serbia on June 29, 1913, carrying hostilities against the Greeks also. Bulgaria, however, was defeated, first at Bregalnica, then in a number of other battles. With the entrance of Rumania into the war on the side of Serbia, Montenegro, and Greece, the Bulgarians sued for peace which was concluded in Bucharest on Aug. 10, 1913. By the Treaty of Bucharest, Serbia was awarded large territories in the Valley of the Vardar and in the southwest toward Albania. (See also separate article BALKAN WARS.)

World War I.—This successful conclusion of the Balkan Wars increased Serbia's prestige with the South Slavs (Serbs, Croats, and Slovenes) in Austria-Hungary, but caused the Austrian Empire to look upon Serbia as a new menace to its own existence. Taking as a pretext the assassination of the Archduke Francis Ferdinand in Sarajevo (Bosnia) by a young Serbian revolutionary (June 28, 1914), Austria-Hungary declared war on Serbia, July 28, a move which resulted in World War I (see WAR, EUROPEAN—*Diplomatic History*).

During the war, Serbia's army was brilliantly

led by Prince Alexander, who, in 1914, had been appointed regent by his aged and ailing father, Peter I. Though vastly outnumbered by the enemy, the Serbians achieved remarkable successes, twice defeating the army of the Dual Monarchy. For more than a year Serbia successfully resisted the invaders, and it was not until both the German and Bulgarian armies threw their might on the side of Austria-Hungary that the Serbs had to give ground. In the memorable and bloody retreat through the Albanian mountains, Alexander succeeded in bringing out of Serbia 200,000 of his soldiers. Aided and equipped by the Allies, this reorganized Serbian Army played an important part on the Salonika front, and succeeded in breaking through the enemy lines at Dobropolje and Kajmakchalan (Kaimakčalan) in September 1918.

On Dec. 1, 1918, Serbia merged its existence as an independent kingdom in the newly created Kingdom of Serbs, Croats, and Slovenes. (See Yugoslavia.)

SERBS, CROATS AND SLOVENES, Kingdom of, (Slav, Kraljevina Srbi, Hrvata i Slovenaca), a union of several Slav states in the Balkan Peninsula, since 1929 known as Yugoslavia (q.v.).

SEREMBAN, sĕ-rĕm'băn, town, British Malaya, capital of the state of Negri Sembilan, Federation of Malaya, 42 miles northwest of Malacca. It is on the west coast railway up the Malay Peninsula, and a branch line connects it with Port Dickson, the state's seaport. Pop. (1947) 35,274.

SERENA, La. See La Serena.

SERENADE, properly, music performed in a clear night; hence a musical entertainment provided by a lover under the window of his mistress. It consists generally of instrumental music, but vocal is sometimes added. The practice existed even among the Greeks and Romans. Such music is sometimes performed merely as a mark of esteem and good will toward distinguished persons, and then is not infrequently accompanied by long processions with torches. Hence the different character of serenades. A single singer may accompany his song with the guitar, mandolin, lute, or the like; or wind instruments may be used, as flutes, horns, clarinets, or hautboys.

SERF, in feudal usage, a member of the class of peasants who were bound to the land of their master, which they cultivated. Under the feudal system, from the vassals of the king downward, the whole community was subject to certain degrees of servitude, and it was only on condition of specific services to be rendered to his superior that any individual held his fief. In the case of the lower classes this servitude amounted to an almost complete surrender of their personal liberty. There were two classes of laborers, the villeins and the serfs proper. The former occupied a middle position between the serfs and the freemen. Henry Hallam (q.v.) remarks, in reference to these two classes, that in England, at least from the reign of Henry II, one only, and that the inferior, existed; serfs were incapable of property and destitute of redress except against the most outrageous injuries. A serf could not be sold, but could be transferred along with the property to which he was attached. The revival of the custom of manumission counteracted the rapid increase of serfs. A serf could also obtain his freedom by purchase, or by residing for a year and a day in a borough, or by military service, or by dying. By these various means the serf population gradually decreased. In most parts of the Continent they had disappeared by the 15th century. The extinction of serfdom in England and Scotland was very gradual. As late as 1574, Elizabeth issued a commission of inquiry into the lands and goods of her bondsmen and bondswomen in specified counties in order to compound for their manumission; and even in the 18th century a species of serfdom existed among Scottish miners. Serfdom in Russia was abolished by a manifesto of Alexander II (q.v.) on March 3, 1861. See also Feudal System.

SERGE, a kind of twilled worsted cloth, used for ladies' dresses, gentlemen's summer suits, and so forth. Navy serge is a thick durable make of this cloth.

SERGEANT, United States Army, a member of the first three grades of the noncommissioned officer corps (corporal is the fourth grade). The three grades are designated as master sergeant, sergeant first class, and sergeant. A sergeant is either a subordinate commander or a technical specialist. The United States Air Force and United States Marine Corps have corresponding grades of sergeants with similar duties. Many state and municipal police departments have a position of sergeant, usually ranking just below that of police lieutenant.

SERGEANT AT ARMS, an executive and disciplinary officer of legislative bodies. In both houses of the Congress of the United States his authority may not be ignored with impunity. In cases of disorder he carries the mace down the aisle of the House. Should any member continue the disorder after this demonstration he is guilty of contempt. The sergeant at arms also serves processes and, if necessary, arrests absent members during sessions when their presence is necessary to constitute a quorum. In the House of Representatives he has charge of the members' payroll.

SERGIPE, sĕr-zhē'pĕ, state, Brazil, smallest of the states of the republic, 8,321 square miles in area. The São Francisco River, on the north, separates it from Alagoas, and Baía (Bahia) bounds the state on the west and south; it is bounded on the east by the Atlantic Ocean. While the coast is flat and sandy, the interior consists of wooded hills. Iron ore and crystal quartz occur. Forests on the slopes of the hills are rich in valuable cabinet woods and dyewoods. Stock raising on the western plateaus is of importance, and sugarcane, cacao, cotton, tobacco, corn, rice, and flax are cultivated. There are sugar refineries, distilleries, flour mills, and tanneries. Aracajú, the capital, is at the mouth of the Cotinguiba River. Pop. (1947) 631,025.

SERGIUS, sûr'jĭ-ŭs, the name of four popes, as follows:

SERGIUS, I: b. Syria, about 630; d. Rome 701. He succeeded Conon in 687. He opposed several provisions of the Quinisext Council of Constantinople in 692 and in consequence Justinian II sent to arrest him. Sergius, however, was protected by the exarch of Ravenna. He died in Rome after a pontificate of nearly 14 years.

SERGIUS II: b. Rome; d. 847. He succeeded Gregory IV in 844, and during his pontificate the Saracens from Africa ascended the Tiber, and plundered the environs of Rome.

SERGIUS III: d. 911. He was raised to the papal chair in 904, after the anti-pope Christopher had been expelled. On the strength of Luitprand's testimony, his character has been deeply calumniated. But contemporary chroniclers speak of him in the highest terms as a pious and enlightened pope. He restored the Lateran Church and filled the Holy See nearly seven years.

SERGIUS IV: d. 1012. He succeeded John XIX, in 1009, and during his pontificate, and as a result of his exhortations, the Italian princes united to drive out the Saracens from the country. It was in his time also that the Normans began to enter Italy.

SERI (sā-rē′) **INDIANS** (Opata, "spry"), an exceedingly primitive tribe of North American Indians, speaking a distinct language and living on and restricted to Tiburon Island, in the Gulf of California, adjacent to Sonora, Mexico. Although known since 1540, when some of Coronado's men visited them, almost nothing was known of their character, save that they were warlike and extremely conservative, until Dr. W. J. McGee led a small expedition among them, in the interests of science in 1894 and again in 1895. The Seris are unusually tall and well-built; they wear little clothing and subsist chiefly on turtles, water-fowl, fish and other food of the sea, eked out with the vegetal and animal products of the mainland desert. Their houses are flimsy bowers of cactus and shrubbery, sometimes rudely shingled with turtle shells and sponges. Bows and arrows are habitually used as weapons, harpoons of cane are employed for taking turtles, and unworked bowlders or cobbles form a ready means for serving meat, crushing bones, mulling seeds, etc. They make graceful balsas of canes lashed together for use in navigating the strait between their island and the mainland; manufacture a very light pottery and some basketry. Shells are used for cups and to some extent for implements. The modern Seris are loosely organized in a number of maternal groups or clans, which are notable for the prominence given to mother-right in marriage and for some other customs. Polygamy prevails. These savages manifest an implacable hatred toward aliens, whether Caucasian or Indian, and the shedding of alien blood is regarded as their highest virtue. Two centuries ago the population of the tribe was estimated at several thousands, but it has been reduced by almost constant warfare, so that now it is barely 350. Consult McGee, 'The Seri Indians'; 17th Report of the Bureau of American Ethnology, Washington, D. C.

SERICULTURE. See Silk and Silk Industry.

SERIES. A series is a succession of numbers or *terms,* usually proceeding according to some definite law. The law of the series may either define how a given term is derived from those that precede it, or it may define a term as a function of the number denoting the position which it occupies in the series. Thus, the series 1, 2, 3, 5, 8, 13, . . . is such that each term after the first two is obtained by adding together the two terms immediately preceding it, and the law of the series might be expressed by the formula $u_{n+1} = u_{n-1} + u_n$, in which u_{n-1}, u_n, u_{n+1} are any three consecutive terms. On the other hand, the series $1, \frac{2}{3}, \frac{3}{5}, \frac{4}{7}, \ldots$ may be defined by the law that the nth term of the series is $\frac{n}{2n-1}$. Each term is then a function of the number n which determines its position in the series. One and the same series may frequently be defined in both ways. Thus, the series, $1, \frac{1}{2}, \frac{1}{4}, \frac{1}{8}, \ldots$ is such that each term may be obtained from the preceding one by multiplying it by $\frac{1}{2}$. It may also be defined by the formula $\frac{1}{2^{n-1}}$ as the expression for the nth term. A series is not uniquely determined when a number of its terms are given. In fact, an infinity of series may be found which include as terms any finite number of arbitrarily assigned numbers. In such a case the simplest law that can be found is naturally to be taken as *the law* of the series. Important use is made of this principle in the physical sciences. Series of numbers frequently arise in connection with experimental observations, which evidently proceed according to some definite law, and it is often of great interest to determine the nature of the law. Such series occur, for example, in the theory of spectrum analysis. Balmer's formula $c\frac{n^2}{n^2-4}$, in which c is a certain constant, determines, for different integer values of n, the wave-lengths of a long series of lines in the hydrogen spectrum. A variety of formulas have been obtained for other spectra. A very instructive account of the methods used in determining such series is given in Kayser's 'Handbuch der Spectroscopie,' Vol. II, pp. 503–573.

A series is said to be *finite* or *infinite* according as the number of its terms is limited or unlimited.

Finite Series.

The law of the series being given, the most important problems relating to a finite series are the determination of the term occupying a given position and finding the sum of the series. The following cases are those of chief interest.

Arithmetic Series.— This series is $a, a+d, a+2d, \ldots, l$, so that the difference between any two consecutive terms is constant and equal to d. The nth term l is evidently obtained by adding d $n-1$ times to a and hence $l = a + (n-1)d$. If S denote the sum of the series, then $S = a + (a+d) + (a+2d) + \ldots + l$. By writing the terms in reverse order, the sum may also be expressed in the form

$$S = l + (l-d) + (l-2d) + \ldots + a.$$

The addition of these two equations gives $2S = (a+l) + (a+l) + \ldots$ to n terms, whence $S = \frac{1}{2}n(a+l) = \frac{1}{2}n[a + (n-1)d]$. In particular the sum of the first n integers 1, 2, 3, . . ., n is

$\frac{1}{2}n(n+1)$, and the sum of the odd integers 1, 3, 5, . . ., $2n-1$ is n^2.

Higher Arithmetic Series.—The general expression $a+(n-1)d$ for the nth term of an arithmetic series is an integral function of the first degree in n. A more general series may be formed in which the expression for the nth term is an integral function of degree s in the n. Such a series is called a *higher arithmetic* series of order s. Let $a_1, a_2, a_3, \ldots$ represent the series. A new series $b_1, b_2, b_3, \ldots$ is formed from this by taking the differences of consecutive terms, so that $b_1 = a_2 - a_1$, $b_2 = a_3 - a_2$, etc. This is called the series of first differences. Let a series $c_1, c_2, \ldots$ be formed from $b_1, b_2, \ldots$ in like manner. These are the second differences. Let $d_1, e_1, \ldots$ be the first terms in the series of third, fourth, . . . differences respectively. Since a_n is a polynomial of degree s in n and a_{n+1} is the same polynomial in $(n+1)$, it follows that b_n, which equals $a_{n+1} - a_n$, is of degree $s-1$ in n; and, finally, that the nth term of the series of $(s-1)$th differences is of degree one in n; that is, the last series of differences is a simple arithmetic series. The series of sth powers of the natural number 1, 2^s, 3^s, . . . , n^s is the simplest example of a higher arithmetic series of order s.

The nth term of the series $a_1, a_2, a_3 \ldots$ can readily be expressed in terms of $n, b_1, c_1, \ldots$ namely,

$$a_n = a_1 + (n-1)b_1 + \frac{(n-1)(n-2)}{1\cdot 2}c_1 + \frac{(n-1)(n-2)(n-3)}{1\cdot 2\cdot 3}d_1 + \ldots,$$

the last term of the formula being of degree s in n. With fractional values of n this formula is much used for the purpose of interpolating between the terms of a given series numbers which shall follow the same general law of variation. For example, suppose it be required to find log 91.43, given log 91 = 1.9590414, log 92 = 1.9637878, log 93 = 1.9684829, log 94 = 1.9731279. The required number is intermediate between log 91 and log 92, which are the first and second terms of the series having log $(90+n)$ for its nth term. As the number 91.43 corresponds to $n = 1.43$, the value of log 91.43 may be calculated approximately by assuming that for a small number of terms the series of logarithms coincides very nearly with a higher arithmetic series of order s, the closeness of the approximation increasing with higher values of s. The first terms of the successive series of differences are $b_1 = .0047464$, $c_1 = -.0000513$, $d_1 = .0000012$, etc. First try $s = 1$, that is, use only two terms of the formula for a_n. This gives log $91.43 = 1.9590414 + .43(.0047464) = 1.9610824$, which is correct to only five decimals. With $s = 2$, log $91.43 = 1.9610886$, which is less than the true value by one unit in the seventh place of decimals. With $s = 3$, that is, by using four terms of the formula for a_n, the value is obtained correctly to seven decimal places.

Geometric Series.— This is composed of the terms, $a, ax, ax^2, ax^3, \ldots$ Each term is formed from the one preceding by multiplying it by x, so that the nth term is ax^{n-1}. If S denote the sum of n terms of the series, then

$$S = a + ax + ax^2 + \ldots + ax^{n-1}.$$

The multiplication of this expression by x gives $xS = ax + ax^2 + ax^3 + \ldots + ax^n$, whence, by subtracting from the preceding, $(1-x)S = a - ax^n$, and accordingly $S = \frac{a(1-x^n)}{1-x}$

Recurring Series.—A more general form of series is the *arithmetico-geometric* series, in which the nth term is of the form $(a+bn)x^{n-1}$ It reduces to the arithmetic series when $x = 1$, and to the geometric series when $b = 0$. This in turn is a special case of a *recurring* series, which is defined as follows: Let $a_1, a_2x, a_3x^2, \ldots, a_nx^{n-1}$ be the terms of such a series. If $r+1$ successive coefficients a_i are connected by a homogeneous linear relation of the form $a_n + p_1a_{n-1} + p_2a_{n-2} + \ldots + p_ra_{n-r} = 0$, in which $p_1, p_2, \ldots, p_r$ are given numbers and $n > r$, the series is called a *recurring series of order r*. The sum of n terms of a recurring series can always be found. The result is a rational fraction in x. The method of summation may be illustrated by the series of order 2. The defining relation is

$$a_n + p_1a_{n-1} + p_2a_{n-2} = 0.$$

Let $S = a_1 + a_2x + a_3x^2 + \ldots + a_nx^{n-1}$. Multiply by $1 + p_1x + p_2x^2$. This gives

$$(1 + p_1x + p_2x^2)S = a_1 + (a_2 + p_1a_1)x + (a_3 + p_1a_2 + p_2a_1)x^2 + (a_4 + p_1a_3 + p_2a_2)x^3 + \ldots + (a_n + p_1a_{n-1} + p_2a_{n-2})x^{n-1} + (a_np_1 + a_{n-1}p_2)x^n + a_np_2x^{n+1}.$$

Since $a_s + p_1a_{s-1} + p_2a_{s-2} = 0$, the above expression reduces to

$$a_1 + (a_2 + p_1a_1)x + (a_np_1 + a_{n-1}p_2)x^n + a_np_2x^{n+1},$$

and hence

$$S = \frac{a_1 + (a_2 + p_1a_1)x + (a_np_1 + a_{n-1}p_2)x^n + a_np_2x^{n+1}}{1 + p_1x + p_2x^2}.$$

The Harmonic Series is $\frac{1}{a}, \frac{1}{a+d}, \frac{1}{a+2d}, \ldots,$ its terms being the reciprocals of the terms of an arithmetic series. The nth term is accordingly $\frac{1}{a+(n-1)d}$. The series is so named because the harmonic tones of a fundamental musical note are produced by the divisions of a vibrating string (or column of air in a tube) into lengths, which form a harmonic series. No formula exists for the sum of n terms of a harmonic series.

Infinite Series.

Convergent Series.—Let $u_1, u_2, \ldots, u_n, \ldots,$ be the terms of an infinite series, and let S_n denote the sum of the first n terms. If S_n approaches a definite, finite limit as n increases to infinity, the given series is said to be *convergent*. If, on the other hand, S_n increases without limit, the series is *divergent*. If S_n does not approach any limit, the series is called indeterminate, as in the case of the series $1-1+1-1+1-\ldots$, for which, S_n takes the values 1 and 0 alternately as n increases. To illustrate these definitions, consider the infinite geometric series $a + ax + ax^2 + \ldots + ax^{n-1} + \ldots$ By the formula given above for the sum of a geometric series $S_n = \frac{a(1-x^n)}{1-x}$. If x is numerically less than unity, x^n diminishes to zero as n increases to infinity, and hence S_n approaches $\frac{a}{1-x}$ as a limit. This expression

is called the *generating function* of the series. The series and its generating function are equal for all values of x for which the series is convergent, that is, for values of x numerically less than 1. But if x is numerically greater than 1, S_n approaches infinity as n increases without limit. The series is then divergent and is no longer equal to the generating function. Similarly, with a recurring series, if its terms approach zero as a limit with increasing n, the terms a_nx^n, $a_{n-1}x^n$, a_nx^{n+1} in the above formula for the sum of n terms of a series of order 2 approach zero and hence S_n has for limit $S=\frac{a_1+(a_2+p_1a_1)x}{1+p_1x+p_2x^2}$. A like result holds for a recurring series of any order.

A series can represent its generating function only for such values of the variable (or variables) on which it depends as will make it convergent, and hence the question of the convergence of a series is of paramount importance. Suppose at first that the terms of the series are positive. Then, if the ratio $u_{n+1}:u_n$ becomes and remains less than a proper fraction k as n increases without limit, the series $u_1+u_2+\ldots+u_n+\ldots$ is convergent. For in that case $u_{n+1}<ku_n$, $u_{n+2}<ku_{n+1}<k^2u_n$, $u_{n+3}<ku_{n+2}<k^3u_n$, and so on. Hence $u_n+u_{n+1}+u_{n+2}+u_{n+3}+\ldots<u_n(1+k+k^2+k^3+\ldots)$. But as k is a positive number less than 1, the infinite geometric series $1+k+k^2+\ldots$ is convergent and equals $\frac{1}{1-k}$. Accordingly $u_n+u_{n+1}+\ldots$ which is less than the finite quantity $\frac{u_n}{1-k}$, is a convergent series. If to this portion of the series the finite sum $u_1+u_2+\ldots+u_{n-1}$ be added, the result is finite and the given series is, therefore, convergent. While the condition just given is sufficient to ensure the convergence of a series it is not necessary. Thus, if a and b are such that $0<a<b<1$, then the series $a+b^2+a^3+b^4+a^5+\ldots$ is convergent, since it consists of the sum of the two convergent geometric series $a+a^3+\ldots$ and $b^2+b^4+\ldots$. But $u_{n+1}:u_n$ alternates between large and small values as n increases and does not, therefore, remain less than a proper fraction.

If some of the terms of a given series are negative, the series is convergent provided that the series obtained by changing the signs of all the negative terms is convergent. For example, the series $1-k+k^2-k^3+k^4-\ldots$, in which k is a positive number, is less than the series $1+k+k^2+k^3+\ldots$ and is, therefore, convergent if $k<1$. It follows, from the preceding considerations that any series is convergent if the ratio $u_{n+1}:u_n$ has a limit numerically less than 1 as n increases to infinity. Thus, for the logarithmic series $\log(1+x)=x-\frac{1}{2}x^2+\frac{1}{3}x^3-\ldots\pm\frac{x^n}{n}\mp\frac{x^{n+1}}{n+1}\ldots$ the numerical value of $u_{n+1}:u_n$ is the same as that of $\frac{x^{n+1}}{n+1}:\frac{x^n}{n}=\frac{n}{n+1}x$. The limit as n increases to infinity is x. The series will accordingly be convergent is x is numerically less than 1. For the exponential series

$$e^x=1+x+\frac{x^2}{2!}+\frac{x^3}{3!}+\ldots+\frac{x^n}{n!}+\ldots,$$

$$u_{n+1}:u_n=\frac{x^n}{n!}:\frac{x^{n-1}}{(n-1)!}=\frac{x}{n}.$$

For any finite value of x this ratio becomes and remains a proper fraction as soon as n exceeds x in absolute value. Hence the series is convergent for all finite values of x.

A series of positive and negative terms is said to be *absolutely* convergent if the series obtained by making all of the terms positive is convergent. When the second series is divergent it sometimes happens that the first series is convergent, in which case it is called *conditionally* convergent, because the value of the sum is conditioned on the arrangement of the terms. For example, the logarithmic series is absolutely convergent for all values of x numerically less than 1. If $x=1$, it becomes $1-\frac{1}{2}+\frac{1}{3}-\frac{1}{4}+\frac{1}{5}-\ldots$, which is convergent and equals $\log 2$. But the series $1+\frac{1}{2}+\frac{1}{3}+\ldots$ obtained by making all the terms positive is divergent. A conditionally convergent series has the peculiar property that by changing the sequence of the terms the sum of n terms may be made to approach any desired limit as n increases to infinity, as may be exemplified by the preceding series. For let c be any number. Select in order as many of the positive terms of $1-\frac{1}{2}+\frac{1}{3}-\frac{1}{4}+\ldots$ as will be sufficient to make a sum greater than c. Then select just enough negative terms so that when added to these the sum shall become less than c. Then add more positive terms until the sum becomes greater than c, and so continue. This process is possible, since the positive or the negative terms alone form a diverging series. With such an arrangement of terms the sum may be made to approach as near to c as desired.

Uses of Series.— Series are of the utmost value as affording a means for the expression of any given function. In particular, functions which are defined as solutions of differential equations are most frequently not expressible in any other form. In the theory of functions as developed by Weierstrass the convergent power-series is made the fundamental instrument of investigation, and from the properties of its defining series the nature of a function is determined. (See COMPLEX VARIABLE, THEORY OF FUNCTIONS OF). The expression of a function in the form of a series is of especial importance when it is desired to calculate its numerical value. It is by this means that various numerical tables, such as the logarithmic and trigonometric, are calculated.

Taylor's series: $f(x)=f(a)+f'(a)\,(x-a)+\frac{1}{2!}f''(a)\,(x-a)^2+\ldots+\frac{1}{n!}f^{(n)}(a)\,(x-a)^n+\ldots$ is the formula most generally useful for the purpose of expanding any given function $f(x)$ in ascending powers of $x-a$, a being a given constant so chosen that the functions and its derivatives $f'(x)$, $f''(x)$, $\ldots$, $f^{(n)}(x)$, $\ldots$ are finite and continuous for values of x sufficiently near to a. Another form for Taylor's series, and the one to which the name is more frequently applied, is obtained by writing h in the place of $x-a$ so that $x=a+h$. The above equation then takes the form

$$f(a+h)=f(a)+f'(a)h+\frac{1}{2!}f''(a)h^2+\ldots+\frac{1}{n!}f^{(n)}(a)h^n+\ldots$$

This series is convergent, if h is not too large. *Maclaurin's series* for the expansion of a function of x in ascending powers of x is obtained as a special case of the first form of Taylor's

series by putting $a=0$. The formula is of course inapplicable if the given function or any of its derivatives are not finite when $x=0$.

For the purposes of numerical calculation it is essential to know how close an approximation to the true value of the function may be obtained by using a given number of terms in Taylor's series and discarding the rest. If S_n denote the sum of the first n terms of the series and R_n the remainder of the series, then $f(x)=S_n+R_n$ and the amount of error introduced by using S_n as the approximate value of $f(x)$ is equal to the remainder R_n. An expression for the remainder in Taylor's series (second equation) was obtained by Lagrange in the form $R_n=\frac{1}{n!}f^{(n)}(a+\theta h)h^n$, in which θ denotes a certain number between 0 and 1. To illustrate, the formula for $\sin(a+h)$ expressed in terms of Lagrange's remainder is

$$\sin(a+h)=\sin a+\cos a\cdot h-\tfrac{1}{2}\sin a\cdot h^2-\frac{1}{3!}\cos a\cdot h^2+\ldots+\frac{1}{n!}\sin\left(a+n\frac{\pi}{2}+\theta h\right)h^n.$$

Since $\sin x$ does not exceed 1 in numerical value the error in discarding the remainder of the series after n terms is not numerically greater than $\frac{h^n}{n!}$. If, for example, knowing $\sin 45^\circ=\cos 45^\circ=\frac{1}{\sqrt{2}}$, it is desired to calculate $\sin x$ for succeeding angles at intervals of 1″, the value for h is taken to be .0000048481, which is the radian measure for 1″ in degree measure. Two terms of the preceding formula give the value of sin 45° 1″ correct to 10 decimals. For the remainder is $R_2=\frac{-\sin\left(\frac{\pi}{4}+\theta h\right)}{2}\cdot h^2$, the first factor of which differs slightly from $-\frac{1}{2\sqrt{2}}$, while h^2 has no significant figure before the eleventh decimal place.

The cases in which Lagrange's formula is practicable for determining the limit of error are comparatively few in number. A convenient limit of error may frequently be found by comparing the given series with a simpler one of less rapid convergence, the limit of error for which can be determined. In particular, a series $u_1-u_2+u_3-u_4+\ldots$ of alternately positive and negative terms which are numerically decreasing toward zero as a limit is convergent, and the error in taking only n terms is less than the next succeeding term u_{n+1}, but greater than $u_{n+1}-u_{n+2}$. For the series may be written $(u_1-u_2)+(u_3-u_4)+\ldots$, which is a sum of positive terms and, therefore, increases, with the number of terms, toward a finite limit, or becomes indefinitely large. But the series may also be written $u_1-(u_2-u_3)-(u_4-u_5)-\ldots$, in which all the terms after the first are negative and hence the sum is less than u_1. The numerical value of R_n is $u_{n+1}-u_{n+2}+u_{n+3}-\ldots$, which, by a repetition of the preceding argument, is greater than $u_{n+1}-u_{n+2}$ and less than u_{n+1}. Thus, for the logarithmic series mentioned above, the error in stopping with the nth term is less than $\frac{x^{n+1}}{n+1}$ (if x is positive). For $x=\frac{1}{10}$ the value of $\log(1+x)$ is given by S_n correct to at least $(n+1)$ decimal places. For values of x near 1 the series converges very slowly. A more rapidly converging series can be obtained by changing x into $-x$, which gives

$$\log(1-x)=-x-\tfrac{1}{2}x^2-\tfrac{1}{3}x^3-\ldots,$$

whence, by subtracting the series for $\log(1+x)$,

$$\log\frac{1+x}{1-x}=2(x+\tfrac{1}{3}x^3+\tfrac{1}{5}x^5+\ldots).$$

In this x is replaced by $\frac{1}{2z+1}$, from which follows

$$\log\frac{z+1}{z}=\log(z+1)-\log z=2\left[\frac{1}{2z+1}+\frac{1}{3(2z+1)^3}+\ldots\right].$$

This series is convergent for all positive values of z. The remainder after n terms is

$$2\left[\frac{1}{(2n+1)(2z+1)^{2n+1}}+\frac{1}{(2n+3)(2z+1)^{2n+3}}+\ldots\right]$$

which is evidently less than the geometric series

$$\frac{2}{(2n+1)(2z+1)^{2n+1}}\left[1+\frac{1}{(2z+1)^2}+\frac{1}{(2z+1)^4}+\ldots\right]$$

the sum of which is $\frac{1}{2(2n+1)(2z+1)^{2n+1}(z^2+z)}$. The error in neglecting R_n is accordingly less than the value of this expression.

The importance for numerical computation of having a series of sufficiently rapid convergence is illustrated by the formula for π. Gregory's series is $\frac{1}{4}\pi=1-\frac{1}{3}+\frac{1}{5}-\frac{1}{7}+\ldots$ which converges so slowly that according to Newton it would require 5,000,000,000 terms and 1,000 years' time to calculate the value of π to 20 decimals. On the other hand, by means of Machin's formula, which converges very rapidly, Shanks has computed the value of π to 707 decimal places.

Divergent Series.— It was supposed by the earlier mathematicians that divergent series were entirely useless. There is, however, a class of such series that have been found not only useful but necessary for the purposes of approximate computation. These have been employed for a long time by astronomers even after their divergence had been proved, their use being justified by the close agreement between calculation and observation. The series in question have the property that the terms at first decrease in numerical value until a certain minimum term is reached, after which they increase without limit. The series is converging as far as its minimum term, beyond which it is diverging. The converging portion of the series frequently affords a very good approximation to the value of the given function. The series for the probability integral $\int_0^x e^{-t^2}dt$ is an example of this kind. By expanding e^{-t^2} in powers of t^2 and integrating term by term, this function is expressed by means of the series $x-\frac{1}{3}x^3+\frac{1}{5\cdot 2!}x^5-\frac{1}{7\cdot 3!}x^7+\ldots$, which is convergent for all finite values of x. For large values of x the convergence is too slow for practical purposes and the series

$$\frac{\sqrt{\pi}}{2}-\frac{e^{-x^2}}{2x}\left[1-\frac{1}{2x^2}+\frac{1\cdot 3}{2^2\cdot x^4}-\frac{1\cdot 3\cdot 5}{2^3\cdot x^6}+\ldots\right]$$

is used instead. While this series is divergent

beyond a certain term, the sum of the converging portion gives an approximation having an error less than the numerical value of the last term used. This approximation is so good and the convergence so rapid that for values of x as small as 3 this series is more convenient to use than the first one and gives a value correct to eight decimals, the first 11 terms being convergent, while for $x = 10$ the first 100 terms are convergent and give a value which is correct to at least 110 decimal places.

The theory of divergent series has recently been receiving considerable attention, chiefly from the French mathematicians. In particular, the problem of determining in how far the divergent series may validly be used as a purely formal representation of a function has been studied by Poincaré, who has developed some important and far-reaching results. An interesting account of the present state of the subject is given by Borel in his 'Leçons sur les séries divergentes' (Paris 1901).

Series of Functions; Multiple Series.— It is often important to express a function as a series the terms of which are given functions such as trigonometric or Bessel functions. Such series are of great service in mathematical physics, especially the *Fourier series* of sines and cosines of multiple angles, which is much used for representing functions having a periodic character. This series was first employed for that purpose by Fourier (1822) in his 'Théorie analytique de chaleur.'

In a simple series $u_1, u_2, \ldots$, the general term u_n is a function of a single integer n defining its position in the series. A *double series* is one in which the general term $u_{m,n}$ is a function of two independent integers m, n. A *multiple series* is one in which the general term is a function of several integers $m, n, p, \ldots$. Such series are of fundamental importance in the study of various classes of functions such as the elliptic functions and the multiple theta functions.

History and Literature.— Some of the properties of arithmetic and geometric series were known in very ancient times, as the oldest manuscript in existence, the Rhind papyrus, which is believed to be a copy of a work dating back 3,000 or more years before Christ, gives an account of some problems which are solved by means of these series. There is considerable ground for supposing that the general formula for the sum of an arithmetic series was known at that time, although it does not occur explicitly in mathematical literature until the time of Archimedes (287–212 B.C.). The formula for the sum of a geometric series was known to the Greeks as it is given by Euclid (about 300 B.C.), while the summation of the infinite series $1 + \frac{1}{4} + (\frac{1}{4})^2 + (\frac{1}{4})^3 + \ldots$ was effected by Archimedes. The general expression for the sum of an infinite geometric series was first given by Vieta (1540–1603 A.D.). A formula for the sum of the squares of the positive integers was given by Archimedes, and for their cubes by Nikomachus (about 100 A.D.). Except for these two particular cases no knowledge of the summation of higher arithmetic series is apparent before the 16th century. The subject as we now know it was developed chiefly in the following century and it took its present form in the 'Ars conjectandi' of Jacob Bernoulli (1713). The name "arithmetic series of higher order" was given by Leibnitz. Newton was the first to recognize the importance of infinite series as an instrument of mathematical investigation. His results were published in 1669 (not printed until 1704) in a work entitled 'Analysis per Aequationes Numero Terminorum Infinitas.' A systematic treatment of series was given by Euler in his 'Introductio in analysin infinitorum' (1748). The principle that an infinite series cannot be safely employed unless it is convergent was first given in this work. Gauss (1813) inaugurated the modern epoch in the theory of infinite series in his memoir, 'Disquisitiones generales circa seriem infinitam, $1 + \frac{a \cdot b}{1 \cdot c} x + \frac{a(a+1) \cdot b(b+1)}{1 \cdot 2 \cdot c \cdot (c+1)} x^2 + \ldots$' He insisted on rigorous tests for convergence and was first to give definite criteria for convergence and divergence. In the 'Cours d'analyse de l'Ecole Polytechnique' (Paris 1821), Cauchy extended the theory of power-series to the expansion of functions of a complex variable and gave the important theorem that a series is convergent if the limit of $u\sqrt[n]{n}$ is numerically less than 1 when n increases to infinity. Further contributions, including additional criteria for convergence and a development of the principle of continuity of series, were made by Abel (1826) in his 'Recherches sur la série,

$$1 + \frac{m}{1} x + \frac{m(m-1)}{1 \cdot 2} x^2 + \ldots$$

'Œuvres complètes,' Vol. I, p. 223). This celebrated memoir is a model of scientific accuracy and comprehensiveness, and exerted an important influence on the growing spirit of rigorous and critical investigation.

Among modern works on series the following may be mentioned: Chrystal's 'Algebra' (Edinburgh 1886), chaps. xx, xxvi–xxxi; Osgood's 'Introduction to infinite series' (Harvard University Publications 1897); Godefroy's 'Théorie élémentaire des séries' (Paris 1903); Runge's 'Theorie und Praxis der Reihen' (Leipzig 1904); Borel's 'Leçons sur les séries à termes positifs' (Paris 1902); Hadamard's 'La série de Taylor' (Paris 1901).

JOHN I. HUTCHINSON,
Late Professor of Mathematics, Cornell University.

SERIES, the term applied to the rocks laid down during an epoch. Series is a subdivision of system (q.v.) just as epoch is a subdivision of period (q.v.).

SERIGRAPH, sĕr'ĭ-grȧf (Lat. *sericum,* silk + Gr. *graphein,* to write), an autographic device for testing the strength of raw silk; (2) one of the graphic arts—an adaptation of an ancient Chinese stencil printing method; also a fine print as distinguished from a reproduction produced by the silk screen printing process.

SERIN, *in ornithology,* a finch, *Serinus hortulanus,* which is closely allied to the canary. Its head is olive-gray and the throat and breast are of a bright gamboge-yellow, shading to white on the belly. It is four and one-half inches long. The serin finch is noted as a lively and indefatigable singer. It is migratory and spends the summer and oftentimes the winter in Middle Europe.

SERINGAPATAM, sĕr-ĭng-ga-pa-tăm′ (properly, Sri-ranga-patanam, "city of Vishnu"), India, a celebrated town and fortress, the former capital of Mysore, 245 miles west by south from Madras, on an island formed by two branches of the Kaveri. The fort, a massive structure, stands on the western end of the island and contains within its walls the ruins of the palace of Tippu Saib (q.v.), a mosque built by the same ruler and an old temple. Just outside of the fort is Tippu's graceful summer palace, now in ruins. At the east end of the island, near the suburb of Ganjam, where almost all the inhabitants now reside, is the mausoleum in which Tippu and his father, Hyder Ali, are buried. The fort was three times besieged by the British, first in 1791 and afterward in 1792 and 1799. On the last occasion the fortress was carried by assault, Tippu being slain. The town once contained about 150,000 persons, but its population in course of time has steadily decreased until now it is only about 7,500.

SERINUS, *in ornithology,* a genus of the sparrow family *Fringillidæ* (q.v.), having a stout cone-shaped bill, broad at the base; the nostrils basal, round and hidden by stiff frontal feathers directed forward, gape straight, without bristles. The serinus is small, compact and active; the legs are short and scutelate; the feet strong; the wings which are moderately long and somewhat pointed have a minute outer primary; and the tail is deeply forked. The serin (q.v.), *Serinus hortulanus,* the *S. canonicus,* the *S. canarius,* the canary, and *S. pusillus,* the red-fronted finch, are inhabitants of the Western Palæarctic regions, but some species are to be found in the Eastern Palæarctic, Oriental and Ethiopian regions.

SERIOLA, *in ichthyology,* a genus of *Carangidæ,* divided into 12 species and inhabiting temperate and tropical waters. The body is oblong and slightly compressed, and the abdomen is rounded; the first dorsal fin is continuous, with feeble spine; villiform teeth in jaws and on the vomer and palatine jaws. The smaller species are valueless, but the larger species which range from four to five feet in length are used as food.

SERIPHOS, sĕ-rī′fŏs, or **SERPHO** (now Serphos), Greece, a mountainous island of the Cyclades group, 50 miles south of Eubœa. It contains iron, copper and lead ore — formerly exploited. The products are chiefly corn and wine. The ancient town participated in the battle of Salamis, furnishing the Athenians with several ships. Seriphos was also a place of exile for the Romans. Pop. 4,000.

SERLIO, sār′lē-ō, **Sebastian,** Italian artist: b. Bologna, 6 Sept. 1473; d. Fontainebleau, 1554. He worked as painter and architect at Pesaro for 14 years, leaving that city (1514) for Rome and Venice, where he became Titian's associate. He published at Venice in 1537 his voluminous treatise 'Regole Generale d'Architectura.' He is supposed to have worked with Pierre Lescot on the Louvre. Primaticcio in 1541 was appointed architect at Fontainebleau with Serlio as assistant.

SERNA Y HINOJOSA (lä-sār′nä ē ēn-ō-hō-sä), **José de la,** famous Spanish general: b. Jerez de la Frontera, 1770; d. Cadiz, 1832. He fought in the Peninsular War against the French and served under Wellington in 1813. After working his way up from the ranks to the position of major-general, in 1816 he was placed in command of the Spanish Royalist army in Upper Peru. In this capacity he was in constant conflicts with the natives and numerous uprisings gave him the opportunity to display his military ability. He was, however, defeated by the patriots at Salta and Jujuy, and owing to disagreements with the viceroy in regard to the conduct of the army during the campaign, resigned in 1819, but was at once made lieutenant-general and president of the council of war. Not long after this he was again appointed to the command of the army to suppress the uprising under San Martin, and on 29 Jan. 1821, upon the deposition of the viceroy Pezuela by his officers, he became viceroy. He was not able to stem the tide of San Martin's successes and on 6 July 1821 was forced to evacuate Lima, retreating to Cuzco. From here he directed his army and maintained it for over three years against the patriots without any assistance from Spain, and keeping his ground in the interior with great skill and resolution. He was finally defeated on 9 Dec. 1824 by the patriot leader, General Sucre, in the battle of Ayucucho. Though outnumbered by the Royalists, the patriots won the battle and Serna with his whole army was captured. He was severely wounded during the fight, and was afterward released and sent back to Spain, where he died at the age of 62.

SEROUS MEMBRANE, a delicate glistening tissue of flattened endothelial cells, supported by a fibrous and elastic layer in which are capillaries and lymphatics, that glistens on exposure. The serous membranes of the human body are so called because moistened by a serous fluid, and form closed sacs. For the most part they line certain cavities of the body and are reflected over the surface of the organ or organs contained in the cavities. The portion of the membrane lining the walls of the cavity is known as the parietal portion, the other is the visceral portion. The serous membranes, six in number, are the peritonæum, lining the abdominal cavity and reflected upon the stomach, liver, intestines, etc.; the two pleuræ lining the thoracic or chest cavity, and reflected upon the lungs; the pericardium, a fibro-serous sac covering or enclosing the heart; and the tunica vaginalis, a closed sac surrounding each testicle. In the female, where the ovum passes from the ovary into the Fallopian tube, the peritonæum is not a closed sac. The serous membranes are kept moistened by a watery lymph-like fluid, a variety of serum, which, if secreted in large quantity, as in dropsy, may produce bad results. Lymphatic vessels open freely on the surface of serous membranes, hence they are sometimes spoken of as lymph-sacs and the cavities they line as lymph-cavities. A grave danger arising from injuries and inflammation of serous membranes is the absorption of septic material by the lymphatics. Dropsical effusions, hemorrhage, formation of pus and deposits of fibrous exudations which cause adhesions and prevent mobility of viscera are the principal results of inflammation of these membranes. See Peritoneum.

SEROW, a shaggy goat-antelope (*Nemorrhœdus bubalinus*) of the Himalayas, where it

frequents, singly, or in family parties, the roughest slopes, at an altitude between 6,000 and 12,000 feet. Its habits are similar to those of the goral, Rocky Mountain white goat (qq.v.) and other members of the genus, all of which are called «serows» by some writers. Consult Lydekker, 'The Game Animals of India' (1907).

SERPA PINTO, sar'pä pēn'tō. See PINTO, ALEXANDRE ALBERTO DA ROCHA SERPA.

SERPENT, (1) *in astronomy,* one of the 48 varieties of ancient constellations extending serpent-like through a wide expanse of sky. (2) *In music,* an almost obsolete bass instrument, consisting of a wooden tube, about eight feet long, increasing conically from one inch diameter at the mouth-piece to four inches at the open end, twisted into U-shaped turns, followed by a large circular convolution. This is covered with leather, and has a mouth-piece like a horn or trombone, and keys for the several notes to be produced. The serpent is a transposing instrument, being in B flat, and the part it is to take is, therefore, written a note higher than its real sound. Its compass is three octaves and one note.

SERPENT-CHARMING, an art largely practised in Egypt, India and other Eastern lands; there are allusions to it in the Hebrew sacred books, namely, Ps. lviii, 5, the adder which will not hearken to the voice of charmers; Eccles. x, 11 and Jere. viii, 17; also in some of the Greek and Latin classics. The power of charming the most formidable serpents, as exercised by the snake-charmers, is unquestionable; nor is it true that before making an exhibition of their art the charmers always extract the poison fangs of the creature, though that is often done. Dr. Davy, in his 'Interior of Ceylon,' expresses his belief in the reality of this singular power. «I have examined the snakes,» he writes, «and have found the fangs in and uninjured. These men do possess a charm, though not a supernatural one — namely, that of confidence and courage. . . . They will play their tricks with any hooded snakes (*Naja tripudians*), whether just taken or long in confinement, but with no other kind of poisonous snakes.» The serpent-charmers are sometimes employed to rid gardens of serpents; and they readily recognize when a serpent is concealed anywhere. In practising their art for this purpose, as also in their exhibitions, they employ a kind of flute in aid of their incantations. When the serpents issue from their hiding places the performer secures them by pinning them to the ground with a forked stick. Those familiar with hypnotism and the French fad for hypnotizing chickens, that flourished in Paris early in the 19th century, will easily recognize that serpent-charming is hypnotic in character.

SERPENT-EAGLE, the secretary-bird (q.v.).

SERPENT-HEAD, or **WALKING-FISH,** a fish of the East Indian and African genus *Ophiocephalus,* the type of a family, allied to the climbing perch, and like it able to live a long time out of the water, and to travel by wriggling through moist grass, from one pool to another. The body is elongate, two to three feet long, and covered with medium-sized scales, those on the depressed head being platelike. About 30 species are known, inhabiting many parts of Asia, the commonest being *O. striatus,* which is sometimes found torpid in dried-up pools and irrigation tanks. When living in muddy water they must rise to the surface from time to time to take in air, or they will smother to death. These fishes are eaten throughout the Orient.

SERPENT-WORSHIP, or **OPHIOLATRY,** a primitive form of religion which is still found existing among uncultured races. The serpent's change of skin may well have been suggestive of resurrection and immortality; the more common supposition that the serpent was regarded by his savage worshippers as the personification of evil and of maleficence, and as a power to be appeased by gifts and worship, does not appear to be justified by the reports of travelers, though the Apophis-serpent of the Egyptian Hades, as well as the wicked Aji Dahaka of the Zoroastrians, were undoubtedly worshipped purely through fear. The brazen serpent erected by Moses in the wilderness and afterward preserved until the days of Hezekiah was broken in pieces by that king (2 Kings xviii, 4), the image having been made an object of religious worship; this was apparently a recrudescence of primitive serpent-worship among the people of Judah. The brazen serpent, it is conjectured by Renan ('Hist. Peuple d'Israël I, xi), was a primitive idol of Jahve. In the Biblical narrative Satan assumed the form of a serpent; among the ancient Egyptians, Typhon was the evil deity, and this idea has generally persisted in Asia, and is apparent in the hieroglyphics of both the Chinese and Mexicans. The serpent whose head the Messiah was to crush, in heathen fable became the hydra of Hercules, and in India the great monster over whom Krishna triumphed, while Roman mythology developed the 100-headed snake slain by Jupiter. We see a trace, and more than a trace, of a primitive worship of the serpent in the great serpent which guarded the citadel of Athens and which was fed every month with honey-cakes; also in the embassage from Rome on the occasion of a plague, to the temple of Æsculapius at Epidaurus, whence was brought a living serpent which was received at Rome with great ceremony. Serpent-worship is still extensively practised in India. Among no people has the mystery of this worship weighed more than on the aborigines of America. It has given name to rivers: examples, Kennebec and Antietam. The name for *spirit* and *snake* are one among the Dakotas, the Shawnees and the Sacs. The Ojibways and other aborigines dread to kill a rattlesnake, and if they find one in their path they pray it to go away and spare them and their families. In Mexico sculptured images of serpents are found as large and as carefully wrought as those of India. There is a vast amount of literature on the subject, which covers the folklore of all peoples, and the serpent seems to have been worshipped more than any other creature, and to have been associated with the idea of fertility or fecundity. In many East Indian ceremonies the serpent deities are constantly associated with women; certain priestesses were selected for their purity, and other women were chosen as «wives» of the snake, and participated in licentious rites. The lore

of the serpents is much mixed with dragon literature.

SERPENTINE, sûr'pĕn-tēn, a hydrated magnesium silicate of monoclinic crystallization, corresponding to the formula $H_4Mg_3Si_2O_9$, and closely related to chlorite. It is formed by the hydration of a mixture of olivine and enstatite, or from the combined action of water and carbon dioxide on olivine alone, giving serpentine and magnesium carbonate. Serpentine is found with a variety of different structures—massive, slaty, foliated, and fibrous, the latter being classed as types of asbestos (q.v.). Chrysotile is one of the fibrous varieties, the fibers being strong, fine, flexible, and easily separable. Its luster is silky; the color is pale green, yellow, or brown. It often occurs in veins in massive serpentine. About 95 per cent of commercial asbestos is chrysotile, the value commercially depending upon fiber length. Serpentine is also closely related to talc (q.v.), the general composition of the two being the same, except for a smaller amount of water of hydration in the talc. Williamsite is an applegreen impure variety of serpentine and is sometimes mistaken for jade. It is often cut and polished. Precious, or noble, serpentine is translucent and of a rich green color.

When not too much broken by joints, serpentine may be used as ornamental or building stone, sometimes being known as serpentine marble. Some varieties are highly prized for their rich green, yellow, and brown colors; others are beautifully mottled with red. This color variation is formed by veins of talc, magnesite, iron oxide, and crystals of pyroxenes running through the massive serpentine. Verd antique or ophicalcite is one of the well-known ornamental varieties of serpentine marble. In the United States serpentine is found in Maine, Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Pennsylvania, Maryland, California, and Arizona. It is also found in Austria, USSR, Norway, Sweden, Scotland, England, and Germany.

SERPENTS or **SNAKES,** of which nearly 3,000 species are known, form one of the principal groups of living reptiles. Anatomical evidence and the fossil record suggest that they were derived from lizard-like ancestors during the Lower Cretaceous period, approximately one hundred million years ago. Snakes belong to the suborder Serpentes (or Ophidia) and are so closely related to the lizards (Sauria) that the two groups are ranked as suborders of the order Squamata, class Reptilia.

Definition.—Many structures characteristic of snakes are found in some lizards. However, snakes ordinarily may be distinguished from other reptiles in having the two halves of the lower jaw connected only by an elastic ligament; in having lost both the pineal opening on top of the head and the upper (temporal) arch of the cheek; and in having the brain case enclosed at the front. Bones of the jaw usually are attached loosely to the skull in order to provide the greater motility necessary for the swallowing of relatively large prey. All snakes lack movable eyelids, external ear openings, and breast bones. The body is elongate and more or less cylindrical, with as many as 435 vertebrae. Snakes lack functional limbs, even though vestiges may be present.

Environmental Requirements.—Snakes, like all other reptiles, lack any internal mechanism for the maintenance of a constant body temperature. They are able to remain active only when the body can be maintained between approximate limits of 60° and 104°F. (15° to 40°C.). Temperatures somewhat higher than 104°F. and slightly below 32°F. can be tolerated for brief periods. By means of their activities snakes are able to control their body temperature; they bask when sunlight is available, but air and ground temperatures are low, or they become nocturnal when ground temperatures are high. Where marked seasonal changes are the rule, snakes hibernate during the winter, or estivate during periods of prolonged hot or dry weather.

Snakes are found in most parts of the world where the subsoil is not permanently frozen, even within the Arctic Circle in the case of a viper inhabiting the Scandinavian Peninsula. Snakes did not succeed in reaching New Zealand, and failed to reach Ireland following the last glacial epoch, during which the island was too cold for reptiles to survive. Many oceanic islands lack snakes, and none is native to Hawaii, although a small harmless species has been accidentally introduced.

Sensory Capacities.—The vision of snakes is moderately acute in many terrestrial or arboreal species, and objects that stimulate them visually are approached for "investigation." These snakes rely largely upon visual cues in detecting the presence of prey; others depend almost entirely upon olfaction. The sense of smell is well developed; odorous particles are picked up by a protrusible, forked, tongue and carried to chemoreceptors (the organs of Jacobson) in the roof of the mouth. The nostrils lead to olfactory membranes, but these are not so important as the organs of Jacobson. Taste buds are not well distributed in the mouth.

Snakes lack a tympanum, and the columella is attached distally to the quadrate. Hence, snakes do not hear in the ordinary sense of the word, although they are particularly sensitive to vibrations received through the substratum. The organs of touch are relatively important organs in snakes. Many boas, pythons, and all pit vipers are equipped with facial or labial pits, extremely sensitive heat receptors, that permit these snakes to detect the presence of warm-blooded prey, and seemingly serve to direct the strike.

Classification.—Systematists recognize thirteen families of snakes, one of them extinct, and there are additional subfamilies. Nearly all families are represented in southern Asia, which may have been the center of origin and dispersal. The largest snakes of the past, as well as the present, belong to the primitive family, Boidae, with two subfamilies, the boas (Boinae), largely restricted to the New World tropics and subtropics, and the pythons (Pythoninae) of the Old World, except for a single species in Mexico. Vestiges of pelvic bones, and external limbs, often mere spurs, are present in boas and pythons, all of which kill their prey by constriction.

The majority of harmless snakes belong to the family Colubridae, a large assemblage with representatives in nearly all parts of the world. There are several subfamilies: Colubrinae, a widespread, progressive group, including racers, king snakes, and their allies; Xenodontinae, some with rear-fangs, but not dangerous to man, mostly restricted to the southern continents, particularly South America; Natricinae, largely composed of

aquatic harmless snakes found in both hemispheres; Homalopsinae, relatively harmless, rear-fanged fresh-water snakes of southeastern Asia and the Indo-Australian Archipelago; Acrochordinae or "wart snakes" of southeastern Asia and the Malay region; Xenoderminae, with a few forms in the tropics of Asia and America; Dipsadinae, slug-eating snakes of tropical Asia and America; Dasypeltinae, egg-eating snakes, a fangless species in Africa and a rear-fanged species in India; Sibynophiinae, snakes with the dentary (tooth-bearing bone in the lower jaw) attached anteriorly only, with a few representatives in Asia, Central America, and Madagascar.

Derived from the colubrid ancestry, but with immovable tubular fangs at the front of the upper jaw, the family Elapidae is comprised of the venomous coral snakes in the Western Hemisphere, the cobras, mambas, and kraits of the Old World, and several groups in Australia where representatives of the family predominate.

The sea snakes (Hydrophiidae), all of them with flattened tails and valvular nostrils, and venomous, are marine relatives of the cobras that inhabit principally the coasts of southern Asia, Australia, and the adjacent islands; one species has reached the eastern coast of Africa and the west coast of North America, although none is found in the Atlantic.

True vipers (Viperidae) are dangerously venomous snakes found only in Africa and Eurasia. Relatively long, tubular fangs attached to a movable upper jaw lie horizontally in the mouth when at rest, and are swung forward when the snakes strike. The common vipers of Europe are relatively small, but the Gaboon viper of Africa may reach a length of six feet, with fangs nearly two inches long. The family is composed of terrestrial, arboreal, and even burrowing forms.

Pit vipers (Crotalidae), similar to the vipers, but equipped with facial pits, include most of the well known venomous snakes in the Western Hemisphere, and there are a few species in Asia and Eastern Europe. Rattlesnakes are especially characteristic of North America, whereas the fer-de-lance and its relatives (of the genus *Bothrops*) are typical of South and Central America. The bushmaster, which may exceed 12 feet in length, the moccasin, and copperhead are also pit vipers.

Families of less importance, mostly specialized burrowers that retain some primitive characters, are the worm snakes (Leptotyphlopidae), found principally in Africa and the Americas, the blind snakes (Typhlopidae), which are circumtropical, the pipe snakes (Anilidae) of tropical Asia and South America, the rough tails (Uropeltidae) of peninsular India and Ceylon, and the Xenopeltidae, represented by a single species in southeastern Asia. The eye is reduced or even vestigial in most burrowers.

Size and Longevity.—Although the extinct snake, Gigantophis of the Eocene of Egypt is estimated to have attained a length of 50 feet, it is doubtful whether the snakes of the past greatly exceeded living forms in size. The reticulated python rarely reaches a length of 32 feet, and sizes exceeding 20 feet are reached by a few others, including the anaconda of South America, which may attain a length of possibly 28 feet. The same snake holds the longevity record, one anaconda having survived for 29 years in captivity. Others have lived for 20 years or more, although it is doubtful whether snakes often survive so long in nature, where they are subject to parasitical diseases and to predation by various birds and mammals. Snakes often eat other snakes, and they are preyed upon by birds, lizards, crocodilians, and even frogs and fish.

Habits and Place in Nature.—Snakes are not gregarious although a few kinds, notably rattlesnakes, aggregate during the winter months in dens or places of concealment where frost does not penetrate. In temperate zones mating is in the spring, but in warmer regions it occurs during any month. Fertilization is internal, the male being provided with paired copulatory organs (hemipenes) that are withdrawn into the base of the tail when not in use. Incubation requires from forty days to over three months; the length of time is partly dependent upon temperature, and varies with individual species.

Many snakes lay eggs, but others are ovoviviparous, retaining the eggs in the body until they are ready to hatch; placenta-like structures are reported for the anaconda. A few oviparous snakes (pythons and some pit vipers) remain coiled about their eggs until they hatch, but parental care is unknown. Myths concerning "snakes swallowing their young for protection," arise from faulty observation.

Propulsion is accomplished more often by sinuous movements of the body, but rectilinear locomotion, involving movements of the broad scales on the belly and muscular action between the skin and the bony skeleton, is characteristic of many thick-bodied venomous snakes. Snakes may also travel by alternately drawing up the body in a series of coils, and then straightening the body. A more specialized type of locomotion, adapted for moving over flat, sandy terrain, is called sidewinding. A sidewinder (or horned rattlesnake) literally rolls along as a sort of modified helix, each point on the body passing through an S-shaped path above the ground, as the body is transferred from one track to the next.

All snakes are carnivorous. Very small snakes eat insects or spiders, larger snakes devour mammals or birds. Those that eat arthropods, mollusks, or other small animals, seize the prey and swallow it while it is still alive, whereas many common snakes subdue their prey by constriction. The muscular coils of the snake are progressively tightened until the creature to be swallowed dies of suffocation. Snakes that have fangs kill the animals they eat by injecting venom through their paired, tubular teeth.

By virtue of their ectothermic (cold-blooded) metabolism, snakes consume relatively small amounts of food in proportion to their bulk. The bare existence of a snake at a temperature of 70°F. requires approximately one fortieth of the energy of a man reckoned for the same surface. Consequently snakes are able to fast for long periods. A large python is known to have survived without feeding for nearly four years.

Large snakes are able to prey upon animals as large as swine and small deer, but the role of the snake in nature is principally that of a predator on small animals. Some, including the bull snakes of the American prairies, and the rattlesnake of the same region, are of importance in rodent control. Approximately one fifth of the species known to science are dangerously venomous; Australia is the only continent where venomous forms outnumber the harmless species. See also REPTILES.

SERPENTS: (1) Bull Snake or Yellow Gopher Snake (*Pituophis catenifer sayi*), nonpoisonous (n.p.), average length 5 feet. (2) Western Ring-necked Snake (*Diadophis amabilis modestus*), n.p., 16 inches. (3) Gray Rat Snake (*Elaphe obsoleta confinis*), n.p., 4 feet. (4) Striped Whipsnake (*Masticophis taeniatus taeniatus*), n.p., 3½-4 feet. (5) Mud Snake (*Farancia abacura abacura*), n.p., 4 feet. (6) Hog-nosed Snake or Puff Adder (*Heterodon platyrhinos platyrhinos*), n.p., 24 inches. (7) Common Water Snake (*Natrix sipedon sipedon*), n.p., 30 inches. (8) Milk Snake (*Lampropeltis doliata triangulum*), n.p., 30 inches. (9) Eastern Copperhead (*Agkistrodon contortrix mokesen*), poisonous, p., 30 inches. (10) Western Diamond Rattlesnake (*Crotalus atrox*), p., 4½ feet. (11) Pigmy Rattlesnake (*Sistrurus miliarius streckeri*), p., 18 inches. (12) Fer-de-lance (*Bothrops atrox*), p., 4-5 feet. (13) Eastern Coral Snake (*Micrurus fulvius fulvius*), p., 30 inches.

SERPENTS

1

(1) De Kay's snake or brown snake (*Storeria dekayi*), nonpoisonous (n.p.), average length 10 inches. (2) Scarlet snake or false coral snake (*Cemophora coccinea*), n.p., 16 inches. (3) Prairie rattlesnake (*Crotalus viridis viridis*), poisonous (p.), 3 feet. (4) Pacific rattlesnake (*Crotalus viridis oreganus*), p., 3 feet. (5) Western ribbon snake (*Thamnophis sauritus proximus*), n.p., 2 feet. (6) Arizona lyre snake (*Trimorphodon lambda*), n.p., 3 feet. (7) Blacksnake (*Coluber constrictor constrictor*), n.p., 4 feet. (8) Cottonmouth or water moccasin (*Agkistrodon piscivorus*), p., 3 feet. (9) Sidewinder or horned rattlesnake (*Crotalus cerastes*), p., 2 feet. (10) Common Eastern king snake (*Lampropeltis getulus getulus*), n.p., 3½ feet.

Bibliography.—A general bibliography will be found in Barbour, Thomas, *Reptiles and Amphibians, their Habits and Adaptations* (New York and Boston 1934); see also Gadow, Hans, *Amphibia and Reptiles* (New York 1901); Pope, C. H., *Snakes Alive and How They Live* (New York 1937); Schmidt, Karl P., and Davis, D. Dwight, *Field Book of Snakes of the United States and Canada* (New York 1941); Cope, E. D., *Crocodilians, Lizards, and Snakes of North America* (Washington, D.C. 1900); and Smith, *The Fauna of British India, Ceylon, and Burma, Reptilia and Amphibia*, vol. 3, (London 1943). Much information will be found in *Copeia*, the journal of the American Society of Ichthyologists and Herpetologists, and in the *Bulletin of the Antivenin Institute of America*, published from 1927 to 1932 in Philadelphia.

CHARLES M. BOGERT,
Chairman and Curator, Department of Amphibians and Reptiles, American Museum of Natural History.

SERPUKHOV, sĕr-poo-hŏf', or **SERPUCHOW**, Russia, a town in the province of Moscow, on the Nara River, 57 miles southwest of the city of Moscow, comprising three divisions. One of these, the Fort, is enclosed by walls, now in ruins. An ancient cathedral is the only building worth noting. Agriculture is an important industry, and there are manufactures of wool, cotton, leather, paper, chemicals, etc. An active trade with the interior is carried on, especially over the Oka River.

SERPULA, a tube-making marine chaetopod worm (see CHAETOPODA), which often lives and reproduces its tubes in such close proximity over considerable areas as to form, with the cemented fragments of coral, sea shells, sand, etc.; caught among its entwined tubes may be large masses of rock. Such are to be seen on the coast of Florida.

SERRA DA ESTRELLA, sär'rä dä ĕs-träl'yä, Portugal, in the Province of Beira, is the highest range of the country, attaining an altitude of 6,540 feet. It belongs to the Guadarramas system, and is a continuation of the Gata Range in Spain, terminating in the Serra de Lousão. Numerous lakes, some of which are warm, occur in the ridge, and the rivers Condicira and Unhaes form fine cascades.

SERRA DO MAR, doo mär, a coastal range of mountains running east by north from São Paulo, Brazil.

SERRANIDAE, a family of acanthropterygian bony fishes typified by the sea bass (q.v.). The body is generally rather short and heavy, slightly compressed, with moderate or large head and covered with usually ctenoid scales. The mouth is usually large and is provided with numerous teeth all of one kind arranged in broad bands on the vomer and palatine bones as well as on the jaws. The fins are well developed and the dorsal spines usually large and strong but variable in number. Sometimes the dorsal and caudal fins are furnished with filaments or streamerlike appendages. The swimbladder is usually comparatively small and attached to the body walls. This is a large family of carnivorous fishes, including about 70 genera and more than 400 species, almost all of which are marine and especially abundant in tropical waters. They are closely related to the Percidae and, like that family, include a large number of valuable food fishes. In North American waters no less than 28 genera and 90 species are found, almost all of which are good and a number very important food fishes. Among them may be mentioned, in addition to the sea bass, the striped bass, white perch, yellow bass, jewfish, groupers and squirrelfish, most of which are described elsewhere in this work.

SERRANO Y DOMINGUEZ, sĕr-rä'nō ē dō-mēn'gāth, **Francisco**, DUKE DE LA TORRE, Spanish statesman: b. Anjonilla, Andalusia, Sept. 18, 1810; d. Madrid, Spain, Nov. 26, 1885. He entered the military college in 1822, became an ensign in 1825 and served in the coast guard until 1833, but after the death of Ferdinand VII he gained favor with Queen Isabella and espoused the cause of the child queen Isabella II, against the Carlists. He played an active part in the troublous politics of Isabella's reign, at times holding high offices in the administration and again at variance with the ministry. For implication in the insurrection of Saragossa in 1854 he was exiled but in June returned and took part in the successful revolution of Espartero and O'Donnell. In 1857 he was sent as ambassador to Paris, and in 1860 he went to Cuba as captain general. In 1866, after the overthrow of O'Donnell's government, Serrano was banished, but in 1868 returned, assisted in overthrowing the queen's army and forced her to leave the country. He then acted as regent until the accession of Amadeus of Savoy in 1870. He was successful in his warfare against the Carlists both in 1872 and in 1874, and during much of the latter year was at the head of the government. He resigned the monarchy into the hands of Alfonso XII, in 1875, but continued active in political life, and in 1883 was appointed ambassador to France.

SERRELL, Edward Wellmann, American civil and military engineer: b. Nov. 5, 1826; d. New York City, April 25, 1906. He entered the engineering profession and was employed on the Erie Railroad, the Central Railroad of New Jersey, the Panama survey, the Niagara Bridge, the Hoosac Tunnel and other large engineering works. He was an assistant to the chief of topographical engineers, United States of America; entered the Federal engineer corps as a colonel in the Civil War; was at the capture of Fort Wagner and devised the Swamp Angel battery that shelled Charleston, S. C. He became chief engineer for the Department of the South, and was in 126 actions, being brevetted brigadier general. He suggested improvements in guns and gun carriages, and issued some 50 reports on railroads and bridges.

SERRES, Dominic, English marine artist: b. Auch, Gascony, 1722; d. London, 1793. He is said to have been a nephew of the archbishop of Rheims and was intended for the church, but this not suiting his taste he ran away from home and became a sailor, eventually becoming master of a Spanish trading vessel. Being taken prisoner by a British warship, he was carried to England, where he afterward resided. Having had some instruction in drawing, he began life in his adopted country as a painter of naval pieces, for which the wars of the period furnished subjects. Serres became a member of the Incorporated Society of Artists in 1765 and exhibited with them for two years. On the establishment of the Royal Academy in 1768 he was chosen one of the foundation members. Among the pictures exhibited by Serres at the

Royal Academy were *The Siege of Fort Royal, Martinique* (1769), and *The Engagement between the Serapis and the Countess of Scarborough with Paul Jones and his Squadron* (1780). In 1792 he was appointed librarian to the academy, and also marine painter to George III.

SERTORIUS, sûr-tō′rĭ-ŭs, **Quintus,** Roman general: b. Nursia, Italy, about 123 B.C.; d. 72 B.C. He distinguished himself as a soldier under Gaius Marius against the Teutones and later in Spain, and held the office of quaestor in Cisalpine Gaul in 91 B.C. During the civil war between Marius and L. Cornelius Sulla, Sertorius declared for the democratic party and aided Marius in seizing Rome. As Marius' representative he went to Hither Spain in 83 or 82 B.C., and drove out Sulla's governor, but was himself driven out of Spain into Mauretania in 81 B.C. Here he successfully resisted efforts to dislodge him and in 80, at the invitation of the Lusitanians, went to Farther Spain, where his personal bravery, rude eloquence, and generous treatment of the natives won him a large following among natives and Romans alike. Marcus Perperna brought him reinforcements in 77 B.C., and in 77–76 he gained control of most of Spain. Sertorius organized an independent government on the Roman model, headed by a Senate of 300 members, and founded a school at Osca (now Huesca) in which the sons of native chiefs were educated in the Roman fashion. He formed alliances with the Mediterranean pirates and with Mithridates VI, king of Pontus in far-off Asia Minor. These proved ineffective, but despite the greater forces at the disposal of the senatorial party in Rome and the arrival in Spain (77 B.C.) of a formidable expedition led by Pompey the Great, Sertorius, though suffering occasional defeats, maintained his position by guerrilla warfare until jealousy among his subordinates caused his murder in 72 B.C., seemingly at the instigation of Perperna, who was quickly defeated and executed by Pompey.

SERUM THERAPY. See VACCINE.

SERVAL, sûr′văl (*Felis serval*), one of the most common cats of the African plains. It has spotted tawny fur and may exceed three feet in length, besides 15 inches of tail. Servals are voracious feeders, hunting small mammals or birds on the ground, and often digging rodents out of their burrows. They are capable of climbing trees as well. Servals are active both by day and night.

EDWARD HODGSON.

SERVANTS OF MARY. See ORDERS, RELIGIOUS—*Roman Catholic Orders* (Servites).

SERVETUS, sûr-vē′tŭs, **Michael** (Span. MIGUEL SERVETO), Spanish physician and theologian: b. Tudela, Navarre, 1511; d. Geneva, Oct. 27, 1553. He was the son of a notary, who sent him to Toulouse to study civil law. Here Servetus became interested in the discussions of the Reformers and began to devote his attention to theology. Subsequently he found his way to Germany and there printed a strongly anti-Trinitarian tract, *De trinitatis erroribus* (1531), which was followed the next year by *De trinitate.* But he found that the expression of his opinions, which finally came to include a denial of infant baptism and of original sin, was as obnoxious to the Reformers as to the orthodox, and he made his escape to France under the name of Michel de Villeneuve. After being employed as a proofreader by the Frellons, publishers at Lyon, Servetus went to Paris in 1536, where he studied medicine and graduated as doctor. In Paris he seems to have encountered John Calvin for the first time. Having quarreled with the medical faculty at Paris, he left that city (1538), studied theology and Hebrew at Louvain, and practiced medicine at Avignon and Charlieu. He continued his medical studies in the school of Montpellier and in 1541 settled at Vienne, becoming physician to the archbishop.

In 1553 Servetus published his matured theological system anonymously under the title of *Christianismi restitutio.* The magistrates of Vienne, however, discovered the name of the author—according to some authorities, with the help of Calvin—and Servetus was tried and convicted of heresy, but managed to escape from prison. He set out for Italy, but some fatal fascination made him go by way of Geneva, where he arrived on Aug. 13, 1553. On the following day he was arrested by the magistrates on a charge of blasphemy and heresy. His writings were sifted for accusations, but the magistrates of Geneva were aware that this was extraordinary treatment of a person who was neither subject nor resident but properly speaking a traveler kidnaped in his passage. They therefore consulted the magistrates of all the Protestant Swiss cantons, who referred the matter to their divines. The latter unanimously declared for punishment, Calvin being especially urgent and emphatic on the necessity for putting Servetus to death. Indeed Calvin had indicated earlier that if Servetus came to Geneva, he would do his best to prevent him from leaving alive. As Servetus refused to retract his opinions, he was condemned on Oct. 26, 1553, and the next day burned as a heretic. Servetus is renowned in medical history as the first to discover the pulmonary circulation of the blood.

SERVICE, sûr′vĭs, **Robert William,** Anglo-Canadian writer: b. Preston, England, Jan. 16, 1874. Service grew up in Scotland and went to school in Glasgow. In 1888 he became a bank clerk, but tiring of the routine, emigrated to Canada, reaching Vancouver Island in 1894. He then traveled up and down the Pacific coast working at various jobs until 1905 when he joined the Canadian Bank of Commerce at Victoria. He was later transferred to Whitehorse and Dawson in the Yukon, resigning in 1909. Service spent eight years in the Yukon, traveling extensively in the subarctic region and becoming widely known for his ballads and other verse depicting frontier life in the Far North in a manner reminiscent of Rudyard Kipling. Subsequently he reported the Balkan War of 1912–1913 for the Toronto *Star.* During the early part of World War I he served as a Red Cross ambulance driver, later joining the Canadian Army. After the war he settled in southern France. He left France for Canada during the German invasion of World War II, but later returned.

Perhaps his best-known ballad is "The Shooting of Dan McGrew," which appeared in his first

book, *Songs of a Sourdough* (1907, reprinted as *The Spell of the Yukon* in 1908). Other books of verse are *Ballads of a Cheechako* (1909); *Rhymes of a Rolling Stone* (1912); *Rhymes of a Red Cross Man* (1917); *Ballads of a Bohemian* (1920); *Songs of a Sun-Lover* (1949); *Rhymes of a Roughneck* (1950); *Lyrics of a Low Brow* (1951); and *Rhymes of a Rebel* (1952). His novels, such as *The Pretender* (1914), *The Roughneck* (1923), and *The House of Fear* (1927), are less well known. *Ploughman of the Moon* (1945) and *Harper of Heaven* (1948) are autobiographical.

SERVICE TREE, *Sorbus domestica,* a member of the rose family (Rosaceae), is native to southern Europe, North Africa, and Asia Minor, and cultivated in the United States. It is larger (to 60 feet tall) than its close relative, the European mountain ash or rowan (*S. aucuparia*), which it resembles in habit. The service tree has spreading branches and a rough, scaling bark. It bears pinnately compound leaves (to 9 inches long) consisting of 11 to 21 narrow-oblong leaflets (to 3 inches long) and white flowers (one half inch across) grouped in tomentose panicles four inches long. Its pear-shaped (var. *pyrifera*) or apple-shaped (var. *pomifera*), somewhat acid fruits are about one inch long, green or brown, and contain grit-cells in their flesh. They are sometimes eaten only when partially rotten (bletted).

SERVICEBERRY. See AMELANCHIER.

SERVITES. See ORDERS, RELIGIOUS—*Roman Catholic Orders* (Orders of Men).

SERVITUDE, *in general usage,* the state or condition of a serf, slave, or bondman; or the state of voluntary or involuntary subjection to a master or employer.

In law, particularly in Roman or civil law, it denotes a charge on property for the benefit of a person or another property. The servitude is either affirmative, obliging the owner of the property to do some act, such as to permit water to be led from his land; or negative, preventing the owner from doing certain acts, such as building walls beyond a certain height or blocking up a window.

SERVIUS, sûr'vĭ-ŭs (in full SERVIUS MARIUS HONORATUS or SERVIUS MAURUS HONORATUS), Latin grammarian: fl. late 4th century A.D. One of the most learned of the classical grammarians, he is known chiefly for his commentary on *The Aeneid, Georgics,* and *Eclogues* of Virgil, which has come down to us in two versions. The longer version was formerly thought to have been enlarged by an unknown author of the 7th or 8th century, but modern scholarship attributes the additions to a work of Aelius Donatus which Servius used in part for his commentary. Servius was also the author of other grammatical works as well as of a commentary on Donatus' *Ars grammatica.*

SERVIUS TULLIUS, sûr'vĭ-ŭs tŭl'ĭ-ŭs, sixth king of Rome: d. 534 B.C. Although the traditional accounts of the Roman monarchy that have come down to us are generally legendary, Servius is almost certainly an actual historical personage. He does not seem to have been an Etruscan, as one account has it, but a Roman or Latin who married the daughter of the fifth king, Lucius Tarquinius Priscus, and succeeded to the throne on the latter's death (the traditional date is 578 B.C.). His reign is said to have been peaceful and to have been marked by constitutional reforms and material progress. The so-called Servian Reform, by which the plebeians were admitted to the Comitia centuriata, probably did not develop until the 5th or 4th century, and the wall which bears his name was not built until 378 B.C. Nevertheless, Servius did conclude the treaty with the Latin League ascribed to him, and he seems to have erected public buildings in Rome. He is said to have been killed in a patrician conspiracy.

SERVOMECHANISM, sûr-vô-mĕk'ă-nĭz'm (also called FEEDBACK CONTROL SYSTEM). Servomechanisms are automatic control systems in which the operation of a high-power device, as one used in pointing a gun or positioning the rolls of a steel mill, is caused to follow closely the command of a low-power device. The high-power and low-power devices are usually remote from one another. The ratio of the power controlled to the power in the control signal may often be a million million to one.

Servomechanisms, or robots as they are often called, are important in manufacturing such necessities as steel, machine tools, and chemicals, in steering ships, aircraft, or guided missiles, in printing colored magazines, in scientific research, and have numerous other applications. They are applied daily to operations that man finds difficult or unpleasant. In response to a signal no greater than the twitch of a muscle, they control great masses. In many of the world's great observatories the light from a star is made to control the motion of a massive telescope to an accuracy of a few wavelengths of light.

The high-power device is called the *controlled member,* and the quantity being controlled is usually its position or speed. The low-power device is called the *command* or reference, and the command signal may also be position or speed. Often, however, the command is the voltage from a radar echo or from a pressure-sensing device, or even the intensity of incident light.

Servomechanisms have an important property that distinguishes them as a class from many automatic control systems, in that the explicit operation of the high-power device is made a function of the *difference* or error between its desired state, or command, and its existing state. In all servomechanisms, the requirements of the command are constantly or intermittently compared with the state of the control, and if there is an error, an adjustment is made.

It is this error-sensing property of servomechanisms that makes possible their remarkably high operating accuracy under widely diverse operating conditions, and it is the means by which this property is achieved that has given rise to the widespread use of the term *feedback control system.* In all servomechanisms, the condition of the output is fed back for comparison with the command, to provide information about the difference or error. The error information is used as a signal to actuate the power-amplifying part of the system and to bring about the desired amount of control. All servomechanisms therefore comprise: (1) a means of measuring what is desired and what is being accomplished; (2) a means of transmitting these measurements

between the remotely located command and the control, and for establishing their difference; and (3) means of amplifying the difference signals and using them to control large amounts of power. The error-sensing and amplifying part of the system is often referred to as the brain or nerve center. Because of their wide diversity of applications, servomechanisms frequently comprise electrical, electronic, hydraulic, mechanical, pneumatic, optical, and thermal components, both singly and in combination.

The principle of feedback is readily understood by reference to an example from everyday life. Consider the situation in a schoolroom. Here the textbook may be thought of as the command. The teacher may be thought of as the nerve center, the student as the controlled member. This situation is depicted in Fig. 1. The quantity being controlled is the student's depth of understanding of the textbook. If the educational process were limited to having the teacher expound on the text while the student merely listened, we would not expect much learning because the teacher would have no means of knowing whether the student really understood or whether what was said was relevant to the learning process. It is for this reason that education makes use of the test or quiz. The teacher receives "feedback" by means of the quiz, which meas-

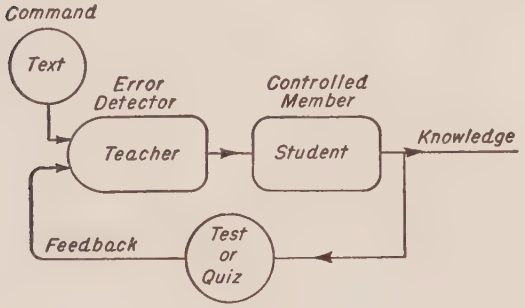

Fig. 1. Diagram of feedback in the schoolroom.

ures how well the student understands. If there is an error in understanding, the teacher can make an adjustment. As a matter of fact, in our daily actions, we frequently operate in exactly the same manner as do servomechanisms—as systems in which the control action is a function of the difference between the state desired and the state existing, this difference being available by feedback from the controlled element to the nerve center of the system.

Fig. 2 illustrates an arrangement of equipment in antiaircraft weapons, where a radar set automatically tracks a target airplane and furnishes information about the target position to a director, which computes where the gun should point so that the projectile and the target will collide after the projectile has travelled the necessary distance. The power servomechanism drives the gun by comparing the actual gun position with the gun position computed by the director and uses the error to actuate the power drive of the gun. Servomechanisms employing the principles shown for the gun occur also in several other places in the director and the radar set, but for simplicity of description are not shown in the figure.

The designers of servomechanisms face many problems when synthesizing the elements that are to go into the system. In aircraft applications,

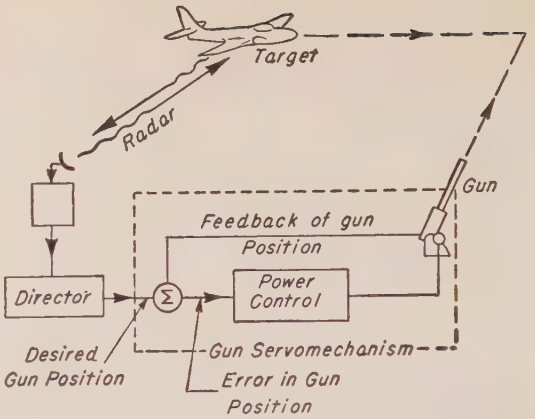

Fig. 2. Antiaircraft gun servomechanism for positioning gun.

their scope is severely restricted by the necessity of combining reliability of operation with compactness in design. The same equipment must operate reliably both on the ground at temperatures ranging anywhere from −40°F. to 120°F. and at altitudes of some 60,000 feet, the temperature range may be even greater. Industrial applications can often tolerate bulkier and heavier equipment, but it must be no less reliable and must often cope with the hazards of contaminated or explosive atmospheres and stand a lot of abuse. Advances in the engineering art have been rapid since the end of World War II and many truly remarkable systems have been evolved.

The performance demanded of servomechanisms also taxes the ingenuity and creative resources of designers. The task is invariably one of designing equipment that will hold a close correspondence between control and command in the presence of widely varying loads and rapidly changing commands. Unless careful attention is paid to the mathematical theory of feedback systems, the performance will tend to become oscillatory or the system will "hunt" as the engineer attempts to reduce the operating errors. Furthermore, servomechanisms theory stipulates this essential law of control for any servomechanism: in the presence of any steady error, the controlled quantity must be the time derivative of the error, that is, in a position control system a steady position error must establish a velocity of the output. Systems in which a steady position error establishes only position at the output are elementary governors or regulators, not servomechanisms.

The crux of the design problem is finding the dynamic behavior of each component in the system. Following the techniques of communications engineering, the so-called frequency-response method of analysis and synthesis is now in wide use. When the parameters of such components as mass, friction, elastance, and sensitivity are known, the frequency-response function can be readily calculated. But in many instances the components are so complicated that experimental methods of measurement must be devised for determining the characteristics. Briefly, the procedure is to energize the components, either singly or as assemblies, with a time-varying sinusoidal signal as shown by curve *A* in Fig. 3. The magnitude and the relative phase of the output response with respect to the constant-magnitude excitation are then measured as the excitation frequency is varied. Curves *B* and *C* show the time-varying excitation and response relations

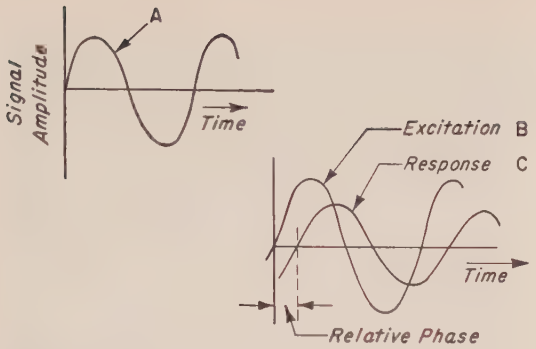

Fig. 3. Time varying (sinusoidal) signal-response relationships.

for a particular frequency. Data as in Fig. 3, for an octave of frequencies above and below the approximate resonant frequency of the system, provide very useful information; from an analysis of such data, a designer skilled in servomechanisms theory can determine the essential design factors, such as gear ratios, amplifier sensitivities, motor or generator sizes, or hydraulic pressures, as the case may be. He may also elect to introduce compensating networks into the system in order to give the required dynamic performance.

For many applications, the design is a compromise, where acceptable accuracy is achieved at a

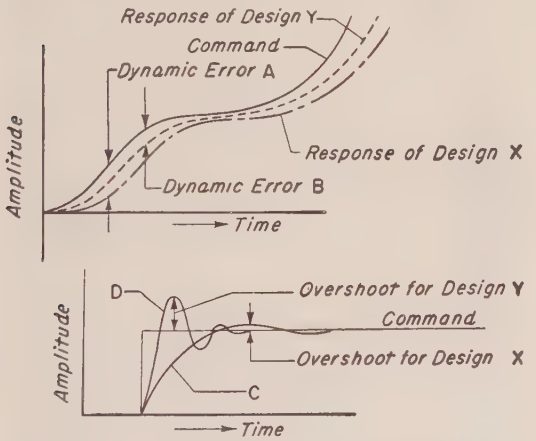

Fig. 4. Showing dynamic error and relative stability.

desirable degree of stability. For example, for a typical time variation of command, design *X* may yield a certain operating error, such as curve *A* in Fig. 4, with a degree of stability for a sudden change in command indicated by the overshoot of curve *C*. Alternatively, design *Y* may yield a smaller operating error, as in curve *B*, for the reduced degree of stability shown by curve *D*. The many factors which influence the design compromise can be evaluated only by competent engineers who have had long and extensive experience with servomechanisms.

Gordon S. Brown,
Massachusetts Institute of Technology.

SESAME, sĕs'ă-mē, a rough, hairy, gummy annual plant (*Sesamum indicum*) about two feet high, with petiolate, ovate-lanceolate leaves, opposite below and alternate above, slightly toothed, and mucilaginous. The flowers are solitary in the axils, pale or rose-colored, five-parted, with irregular-lipped corolla, having the tube curved downward and dilated above the oblique base. Sesame has been known from ancient times and originated in the East, where it is cultivated for the sake of its black or white seeds. It is easily grown, does not object to poor soil, and has even been introduced to gardens in America. The plant has run wild in the Southern states.

The seeds are very tiny, but sweet and oleaginous, and are used for food by Oriental peoples

Sesame (*Sesamum indicum*) with detail of fruit.

and imported into Europe for crushing. They will yield half of their weight in oil, which is yellow, limpid, inodorous, and keeps for years without becoming rancid. It is of great economic value, second only to coconut oil in the variety of its uses, and can be employed instead of olive oil in many ways, as for culinary purposes, food, medicine (having a laxative effect), cosmetics, and soaps. It is also employed as an adulterant in olive oil, and may itself be adulterated with peanut oil. Sesame oil is also known as benne, gingelly or gingili, and teel or til. The cake left after the oil has been expressed makes a good feed for cattle and is sometimes food for the poor.

SESAMOID BONES, sĕs'ă-moid, rounded bodies, at first cartilaginous and then bony, found in the tendons of muscles. They derive their name from their resemblance to sesame. The patella or kneecap is a sesamoid bone. Another is developed in the upper joint of the thumb, and at the corresponding joint of the great toe, these increasing the leverage of the short flexor muscles of the thumb and great toe respectively. Sesamoid bones are far less numerous in man than in most mammals.

SESOSTRIS, sē-sŏs'trĭs (Greek corruption of the Egyptian Senusret, sĕn-ŭs'rĕt, Senusrit, sĕn-ŭs'rĭt, or Senusert, sĕn-o͞o'sĕrt), the name of three ancient Egyptian kings of the 12th dynasty.

Vigorous rulers who suppressed the power of the provincial nobility, they extended their domain southward in the Nile Valley, but made no major expeditions into Asia.

Sesostris is also the name of a legendary Egyptian king, the story of whose conquest of a vast area Herodotus (Book II) says he got from Egyptian priests. This king apparently is a composite of Rameses II and other rulers, including perhaps the historical Sesostris III.

Sesostris I, second king of the 12th dynasty, reigned for about 44 years, approximately from 1971 to 1928 B.C., after 10 years as coregent with his father, Amenemhet I, the dynasty's founder. As coregent the son seems to have led expeditions against the Nubians and Lybians, after his father's death completing the conquest of Nubia and invading Cush. His pyramid, like his father's, was built at El Lisht, near the capital Amenemhet I had founded to replace Thebes. Sesostris I was succeeded by his son Amenemhet II. An early example of narrative fiction, *The Romance of Prince Sinuhe*, is placed in this period, relating Sinuhe's flight at the death of Amenemhet I, his life in exile, and his return to Egypt late in the reign of Sesostris I.

Sesostris II, fourth king of the dynasty, reigned for about 19 years, approximately from 1897 to 1879 B.C., after three years as coregent with his father, Amenemhet II. His pyramid was built at El Lahun (Illahun).

Sesostris III, son of Sesostris II and fifth king of the dynasty, reigned for some 36 years, approximately from 1878 to 1843 B.C. He had a canal dug through the first cataract of the Nile, campaigned in Nubia, and extended the boundaries of Egypt southward beyond the second cataract, erecting two boundary stele at Semneh, on the Nile, about 35 miles southwest of Wadi Halfa. His pyramid was built at Dahshûr. He was succeeded by his son Amenemhet III.

SESQUICENTENNIAL EXPOSITION, sĕs-kwĭ-sĕn-tĕn'ĭ-ăl, an exposition held at Philadelphia, Pa., from June 1 to Nov. 30, 1926, to commemorate the 150th anniversary of the signing of the Declaration of Independence. Among the outstanding buildings were the Palace of Liberal Arts and Manufactures, and the Palace of Agriculture and Food Products. From the patriotic standpoint, the exposition achieved its purpose, but financially it was not a success, and the city of Philadelphia had to issue bonds to cover bills aggregating $5 million. The total cost was estimated at $18 million. The attendance was about 6 million.

SESTERTIUS, sĕs-tûr'shĭ-ŭs, or **SESTERCE,** sĕs'tûrs, an ancient Roman coin worth 2½ asses. Originally it was of silver, but from the time of Augustus it was brass. The sestertius was the fourth part of a denarius, and when in later times the weight of the as was reduced, and 16 asses were reckoned to a denarius, the sestertius still retained the same proportion to the latter coin, and thus became equal to four asses. The value of the sestertius, therefore, varied with that of the denarius. About the close of the republican period, when the denarius is calculated to have been worth about 17 cents, the sestertius would be worth 5 cents.

The sestertius was the unit most commonly employed by the Romans in reckoning large sums of money. For sums below 1,000,000 sestertia, the ordinary cardinal numerals were used with sestertii or sestertia, as the case might be: but if the sum amounted to 1,000,000 or more, a numeral in *ies*, after which *centena millia* (100,000) had to be understood, was connected with sestertium (for example, *quadragies sestertium* is 4,000,000 of sestertii, that is, *quadragies centena millia sestertiorum nummorum*). Sometimes the numeral adverb was used alone, and *decies ei dedit* signifies *decies sestertium*, that is, *decies centena millia sestertiorum*, or 1,000,000. The sestertius was often expressed by the symbol HS, which is explained as a corruption of IIS, that is, II, the Roman numeral two, and S for *semis*, half.

SESTINA, sĕs-tē'nà, an extremely intricate form of verse invented by Arnaud Daniel, a Provençal troubadour, toward the end of the 12th century, and adopted by Spanish, Portuguese, and Italian poets, notably Dante Alighieri and Petrarch. It consists of six six-line stanzas; the last word of each line of the first stanza is repeated as the last word of a line in each succeeding stanza, but in different order. Provençal poets set the rhyme scheme as follows: first stanza, 1,2,3,4,5,6; second, 6,1,5,2,4,3; third, 3,6,4,1,2,5; fourth, 5,3,2,6,1,4; fifth, 4,5,1,3,6,2; sixth, 2,4,6,5,3,1. After the sixth stanza there is a three-line envoy in which the six rhyme words are repeated, three at the end of the lines and three in the middle. It will be noted that in each stanza after the first, the first line ends with the same word as the last line of the preceding stanza, and the second line ends with the same word as the first line of the preceding stanza.

In France, the form was revived by the *Pléiade* poets, notably Pontus de Thiard in the 16th century, and it was used extensively by Comte Ferdinand de Gramont in the 19th century. In Germany it was adopted by various 17th and 19th century poets. Sir Edmund William Gosse awakened interest in the sestina among modern English poets in 1877, and Algernon Charles Swinburne employed it with remarkable success in later decades. Ezra Pound and W. H. Auden are among 20th century poets who have utilized this intricate verse form.

SESTINI, sĕs-tē'nĭ, **Benedict,** Roman Catholic clergyman, mathematician, and astronomer: b. Florence, Italy, March 20, 1816; d. Frederick, Md., Jan. 17, 1890. He was ordained in 1844 and taught higher mathematics at the Roman College until the Revolution of 1848 forced his flight from Rome. He arrived in the United States the same year and entered Georgetown University, where he taught mathematics. In 1869 he transferred to the Jesuit Seminary at Woodstock, Md., continuing to teach mathematics until 1884, when he retired to Frederick. In addition to mathematical treatises, his chief work in astronomy is *Catalogue of Star-Colors* (1845 and 1847).

SESTIUS, sĕs'chĭ-ŭs, or **SEXTIUS,** sĕks'-tĭ-ŭs, **Publius,** Roman politician. In 63 B.C., as quaestor, he helped Cicero suppress the conspiracy of Catiline. He became a tribune in 57 and was active in recalling Cicero from banishment. Accused the following year of using illegal force, he was defended by Cicero in an oration still extant, and with the powerful support of Pompey was acquitted. In 53 Sestius became a praetor. During the civil war of 49 he sided at first with Pompey, then joined Caesar.

SESTOS, sĕs'tŏs, ruined town, Turkey in Europe, on the Thracian shore of the Dardanelles (Hellespont), at the strait's narrowest point

opposite the ancient town of Abydos in Asia Minor. The site is just northeast of the modern Turkish town of Eceabat. It was the invasion point for Xerxes I in 480 B.C. when he crossed the Dardanelles with his army over a bridge of boats and marched through Thrace, Macedonia and Thessaly. Sestos also is the scene of the legendary romance of Hero and her lover Leander, who supposedly swam across the Hellespont from Abydos each night to meet her.

SET OFF, in law, an actionable counterclaim or cross-demand which a defendant sets of against a plaintiff's demand. It may reduce the plaintiff's claim or extinguish it, according to the amount involved. It differs from a recoupment in that it does not necessarily arise out of the transaction which brings on the plaintiff's action. The right of set off exists only for liquidated claims or for claims which can be ascertained by calculation.

SETE, sĕt (formerly CETTE), seaport, France, located in Hérault Department, on the Mediterranean Sea, about 17 miles southwest of Montpellier. This fortified port is situated on a sandy strip of land between the Étang de Thau lagoon and the Gulf of Lions. It lies at the base of 591-foot Mont St. Clair and is intersected by a network of canals and slips. After Marseille it is France's second Mediterranean port. A wine-export center, Sète also manufactures chemicals, electrical equipment, and wine casks, and produces vermouth. Other industries include petroleum refining, sardine canning, and olive preserving. The port was built during the 17th century by Jean Baptiste Colbert, controller general of finance under Louis XIV, and was fortified in the 18th century. It suffered heavy damage during World War II. Pop. (1946) 29,914.

SETE LAGOAS, sâ'tĕ lȧ-gō'ȧs, city, Brazil, situated in Minas Gerais State, about 35 miles northwest of Belo Horizonte. It is served by a railroad, and is the state's leading center for marble quarrying and quartz crystal mining. It also has textile mills and ships sugar, cotton, and cereals. An experimental wheat station is located here, and caves in the vicinity have yielded rare fossils. Pop. (1940) 10,537.

SETH, sĕth, or **SHETH,** shĕth, in the Old Testament, the third son of Adam, born after Abel's death, according to Genesis 4:25. Another tradition, based on Genesis 5:3, makes Seth the first-born son of Adam and Eve. He was the father of Enos or Enosh, and the genealogical table in I Chronicles 1:1 mentions him as an ancestor of Noah. Luke traced him as an ancestor of Christ (Luke 3:38). He was made the object of special reverence by a heretical Jewish sect called the Sethites, whose doctrine was later adopted by a Christian Gnostic sect as well.

SETH, Andrew (later known as ANDREW SETH PRINGLE-PATTISON), Scottish philosopher: b. Edinburgh, Scotland, Dec. 20, 1856; d. near Selkirk, Sept. 1, 1931. He taught logic and philosophy at the University College, Cardiff (1883–1887), and at St. Andrews (1887–1891), and then was professor of logic and metaphysics at the University of Edinburgh for 28 years until 1919. In 1898 he added Pringle-Pattison to his name as a condition of accepting the bequest of The Haining, an estate near Selkirk. His philosophical position has been described as "liberal traditionalist." Among his works are *The Development from Kant to Hegel* (1882); *Scottish Philosophy* (1885); *Man's Place in the Cosmos* (1897); *The Philosophical Radicals* (1907); *The Idea of Immortality* (1922).

SETI I, sĕ'tē (Gr. SETHOS), Egyptian king of the 19th (Diospolite) dynasty. The son of Rameses I and father of Rameses II, he reigned from 1313 to 1292 B.C. He conquered Palestine, fought successfully against the Libyans to the west, and with less success against the Hittites in Syria. Seti is noted for the splendid temple of Osiris he built at Abydos and also for the hall of columns, started by his father, which he completed at Karnak.

SETIF, sā'tēf (ancient SITIFIS), city, Algeria, located in Constantine Department on the Algiers-Constantine railroad, about 70 miles southwest of Constantine. It is situated in the High Plateaus at an altitude of 3,600 feet in a cereal-growing region. A local trade and communications center, it has a grain and livestock market, manufactures carpets, and mills flour. Sétif dates back to the 1st century A.D. when the Romans founded it as a veterans' colony. The French established the modern city as a fortified post in 1838. Pop. (1948) 39,883.

SETON, sē't'n (also SEYTON or SEATOUN), name of a Scottish noble family, including:

GEORGE SETON, 5TH LORD SETON: b. ?1530; d. Jan. 8, 1585. When Mary, Queen of Scots, assumed the throne of Scotland in 1561, he became a member of her Privy Council and master of the household, remaining one of her most loyal supporters for the rest of his life. Mary spent her honeymoon with Lord Darnley at Seton's estate in East Lothian, took refuge there for a time after the assassination of David Rizzio (1566), and again after the death of Darnley (1567). Seton aided her escape from Lochleven in 1568 and fought under her standard at Langside, where he was taken prisoner. After Mary's internment in England, he became temporarily reconciled with the regent, James Douglas, 4th earl of Morton, but later turned against him and was one of the judges at Morton's trial in 1581.

SIR ALEXANDER SETON, 1ST EARL OF DUNFERMLINE: b. ?1555; d. near Musselburgh, Midlothian, Scotland, June 16, 1622. Fourth son of the preceding, he was originally intended for a career in the Catholic Church, and as a youth attended the College of Jesuits in Rome. Eventually he turned to the law and became a Protestant, but retained strong Catholic sympathies. He became a member of King James VI's Privy Council in 1585; lord president of the Court of Session in 1593; guardian of the infant Prince Charles, later King Charles I of England, in 1600; and vice chancellor of Scotland in 1604, when he also rendered valuable service as a member of the commission which negotiated the union with England under King James. In 1606, Seton was named chancellor of Scotland and earl of Dunfermline. He was a member of the English Privy Council from 1609 and one of King James' principal advisers.

CHARLES SETON, 2ND EARL OF DUNFERMLINE: d. January 1673. Son of the preceding, he was one of the leaders of the Scottish army which in

the First Bishops' War (1639) successfully resisted Charles I's attempt to impose episcopal church government in Scotland. He was also a member of the commission which negotiated the Treaty of Ripon (1640), ending the Second Bishops' War. In November of the latter year he was appointed to Charles' Privy Council, and after the king's execution, became an active supporter of Charles II. At the Restoration he was made a privy councilor and, in 1671, lord privy seal.

SETON, Elizabeth Ann (nee BAYLEY; usually called MOTHER SETON), American religious leader: b. New York, N. Y., Aug. 28, 1774; d. Emmitsburg, Md., Jan. 4, 1821. The daughter of a Columbia College anatomy professor, she married William Magee Seton, a merchant, in 1794, and in 1797 founded New York's first charitable organization, called the Society for the Relief of Poor Widows with Small Children. After her husband's death, she joined the Roman Catholic Church in 1805. Four years later, at Emmitsburg, Md., she organized a community of women called the Sisters of St. Joseph (later the Sisters of Charity of St. Joseph), which was modeled on the Daughters of Charity of St. Vincent de Paul in France. Mother Seton served as the first superior of the order, which grew to some 20 communities before her death in 1821. Its members were active in charitable and educational work, and were chiefly responsible for the establishment of the parochial school system in the United States. The organization became a section of the Daughters of Charity of St. Vincent de Paul in 1850.

Consult Seton, Robert, *Memoirs, Letters and Journal of Elizabeth Seton,* 2 vols. (New York 1869); and Burton, Katherine, *His Dear Persuasion* (New York 1940).

SETON, Ernest Thompson (originally ERNEST SETON THOMPSON), American author and illustrator: b. South Shields, Durham, England, Aug. 14, 1860; d. Santa Fe, N. Mex., Oct. 23, 1946. He was brought up and educated in Canada, living much of the time in the backwoods and later on the Western plains of the United States. He studied art at the Royal Academy in London and then in Paris from 1890 to 1896. Seton is noted for his many self-illustrated stories of animal life, his most popular book being *Wild Animals I Have Known* (1898; new ed. 1942). In 1902 he founded the Woodcraft Indians, an outdoor organization for children which later became the Woodcraft League of America. He was one of the founders of the Boy Scouts of America, and served as its chief scout from 1910 to 1915. Among his best-known stories are *The Trail of the Sandhill Stag* (1899); *Biography of a Grizzly* (1900); *Lives of the Hunted* (1901); *Two Little Savages* (1903); *Biography of an Arctic Fox* (1937); and his autobiography, *The Trail of an Artist-Naturalist* (1940).

Consult *Ernest Thompson Seton's America,* ed. by Farida A. Wiley (New York 1955).

SETON HALL UNIVERSITY, a Roman Catholic institution in New Jersey, founded in 1856 as Seton Hall College by James Roosevelt Bayley, than bishop of Newark, and Bernard John McQuaid, its first president. It was named in memory of Elizabeth Ann Seton (q.v.). Originally located in Madison, N. J., the campus was moved to South Orange in 1860, and branches have since been established in Newark, Paterson, and Jersey City, N. J. Seton Hall became a university in 1950. Besides the undergraduate colleges, there are schools of education, business, law, and nursing, and a graduate faculty which confers masters' degrees in a number of fields.

Seton Hall was at one time a men's college exclusively, but it now admits women to all its divisions except the undergraduate college at South Orange. The United States Army sponsors a Reserve Officers' Training Corps program at the institution, specializing in military police and military government training.

SETON-WATSON, -wŏt's'n, **Robert William,** British historian: b. Ayton, Perthshire, Scotland, Aug. 20, 1879; d. Skye, Scotland, July 25, 1951. He was educated at Winchester and at New College, Oxford (B.A., 1902; D.Litt., 1910), and from 1903 to 1906 he studied at the universities of Berlin, Paris, and Vienna. An expert on central Europe and the Balkans, he was professor of central European history at the University of London (1922–1945) and professor of Czechoslovak studies at Oxford (1945–1949). He founded the magazine *New Europe* (1916), and was joint editor, with Sir Bernard Pares, of the *Slavonic Review* (1922–1949). His works include *The Southern Slav Question* (1911), *The Rise of Nationality in the Balkans* (1917), *Europe in the Melting Pot* (1919), *Slovakia Then and Now* (1931), *Britain in Europe, 1789–1914* (1937), *Britain and the Dictators* (1938), *From Munich to Danzig* (1939), and *History of the Czechs and Slovaks* (1943).

SETTEMBRINI, sāt-tâm-brē'nē, **Luigi,** Italian writer and patriot: b. Naples, Italy, April 17, 1813; d. there, Nov. 3, 1876. He was educated at the College of Maddaloni and studied law at the University of Naples. In 1835 he became professor of rhetoric at the College of Catanzaro, where he was co-founder of a secret society called "The Sons of Young Italy." His propaganda for Italian unity led to his arrest in 1839, and he remained a political prisoner in Naples until 1841. In 1848 he was one of the founders of "The Grand Society of Italian Unity," and the following year was again arrested. This time he was imprisoned for about 10 years, most of the time in the Santo Stefano penitentiary. In 1859 he was deported to America, but with the help of his son Raffaele he managed to divert the ship to Ireland, where he escaped. He returned to Italy in 1860, and after the Kingdom of Italy was established he became professor of the history of Italian literature at the University of Naples. Later, in 1873, he became a member of the Italian Senate. His most notable publication is *Lezioni di letteratura italiana,* in three volumes (1866–1872).

SETTERS, a breed of dogs named from their former habit of crouching, or "setting," on observing the game which they are trained to hunt. In modern days, however, the setter remains erect on coming up with his quarry, and points his nose at it, as does the pointer. Setters require much exercising. They are marked for their handsomeness, intelligence, and pleasant dispositions, and they make good family dogs. The three different types vary in color. The English setter is among the foremost of hunting dogs; it is adapted to colder climates than is the pointer. The Gordon setter appears to be especially

adapted to woodcock shooting. The Irish setter, with its coloring of chestnut or mahogany, is a favorite at bench shows. See Dog.

SETTIGNANO, Desiderio da. See Desiderio da Settignano.

SETTLE, sĕt'l, **Elkanah,** English poet, playwright, and pamphleteer: b. Dunstable, England, Feb. 1, 1648; d. London, Feb. 12, 1724. He entered Trinity College, Oxford, in 1666, but left without taking a degree, and went to London. Beginning with *Cambyses, King of Persia* (1666), he wrote a series of heroic tragedies, the most successful of which was *The Empress of Morocco* (1671). For a time he was regarded as a rival of John Dryden, who satirized him as Doeg in *Absalom and Achitophel.* Settle was appointed city poet in 1691, but died penniless in the Charterhouse. Although his dramatic style is bombastic, he is credited with having understood theatrical production and the use of scenic effect.

SETTLEMENT, Act of. See Act of Settlement.

SETTLEMENTS, Social. See Social and University Settlements.

SETUBAL, sĕ-tōō'b-l (formerly called in English St. Ubes or St. Yves), seaport, Portugal, capital of Setúbal District, situated in Estremadura Province on the Bay of Setúbal, about 20 miles southeast of Lisbon. It is Portugal's second-best harbor, after Lisbon, and its third largest city. A leading sardine-canning center, its manufactures include fertilizer, cement, pottery, corks, biscuits, and soft drinks. Shipbuilding and distilling are other important industries. Setúbal also is a trade center for muscatel wine and oranges, and it has sizable saltworks. During the reign of John II (1481–1495) it was a royal residence, but most of its historic buildings were destroyed in a severe earthquake in 1755. Ruins of Cetobriga, an ancient Roman town, were excavated on the promontory opposite Setúbal in 1850. Pop. (1950) 44,030.

SEURAT, sû'rà, **Georges,** French painter: b. Paris, France, Dec. 2, 1859; d. there, March 29, 1891. He studied at the École des Beaux-Arts under Henri Lehmann, a former pupil of Jean Auguste Dominique Ingres, and in 1884, with Paul Signac, formed a new group called the neo-impressionists. Seurat's work was a refinement of the impressionists' broken-color technique. He built up his forms by juxtaposing small dots of primary colors in systematic patterns, producing an effect of diffused light and atmospheric vibration without sacrificing color. This method was called pointillism or, by the artists themselves, divisionism. Seurat's work also has been acclaimed for its well-developed, almost geometric design. His *Un dimanche à la Grande Jatte* (1886), a characteristically large canvas now at the Chicago Art Institute, is generally considered his masterpiece. *Baignade* (1884), his first neoimpressionist painting, is at the Tate Gallery in London. Before his death at the age of 31, Seurat painted four other large canvases; he has also left a number of fine drawings of dock scenes in Brittany. Examples of his work are found at the Barnes Foundation in Philadelphia and at the Louvre in Paris.

Consult Pach, Walter, *Georges Seurat* (New York 1923); and Laprade, J. de, *Georges Seurat* (Paris 1945).

SEVAN, sĕ-vän' (Turk. Gökcha; ancient Lychnitis), lake, east central Armenian SSR. It is at an altitude of 6,285 feet, and is 546 square miles in area. The Zanga River is its outlet. Evaporation of the lake's waters has been reduced and water outflow increased by the Sevan-Zanga hydroelectric project.

SEVASTOPOL, sĕ-văs'tô-pôl (formerly Sebastopol), city, USSR, located in RSFSR, in the southwest Crimea, on the Black Sea. Sevastopol Bay, the Black Sea's best natural harbor, is large and deep. Four miles long and one-half mile wide, it receives the Chernaya River at its eastern end. The city is an important naval base and shipbuilding center, and has light manufacturing. Its main section is located on a slope between the bay and its southern arm. Center of a Crimean health resort area, the city has an institute of physiotherapy; its museums have cultural importance. The Malakhov, or Malakoff, is a fortification in the southeastern part of the city which was captured after a long siege in 1855, during the Crimean War, and in 1942, during World War II. Between Sevastopol Bay and the Black Sea extends a promontory on which, three miles west of the city, was located a Greek colony known as Chersoneus Heracleotica. Founded in the 5th century, the colony later became a trade center under the Byzantine Empire. Ruins of the colony may be seen.

Sevastopol itself was originally the Tatar village of Akhtiar, founded in the 16th century, and was annexed under Catherine the Great of Russia in 1783. Thereafter, it was the principal Russian naval base on the Black Sea. It was besieged by Allied forces for 11 months during the Crimean War in 1854–1855, the Russians retiring after the town had been destroyed. The French and English engineers then blew up the docks and forts, which, by the Paris Treaty (1856) were not to be rebuilt. These restrictions were annulled by the London Conference of 1871, and the docks and forts were restored by the Russian government. Since 1890, the port has been exclusively a military base, guarding the Black Sea entrance to the Ukraine and to Caucasia, and foreign trade at the port is held down to the minimum in goods required for use by the Soviet government. The city was shelled during World War I. During World War II it underwent a siege comparable to that which it experienced in the Crimean War. It fell in July 1942, after being besieged for eight months by the Germans. Soviet forces stormed it in 1944, and regained it. After the war considerable rebuilding was undertaken. Sevastopol was given independent administrative-economic status within the RSFSR in 1948. Pop. (1939) 111,946. See Crimea—*The Crimean War*; World War II—*Crimean Campaign and Battle for Kharkum* and *The Russian Offensive.*

SEVEN, a number regarded in many religions as especially sacred, mystical, and symbolical. In the Bible, the work of creation having been completed in six days, the Creator rested on the seventh. Egypt's seven years of plenty were succeeded by seven years of famine (Genesis 41:46-56); for seven days the waters of Egypt were turned into blood (Exodus 7:20-25). Two of the three pilgrim festivals of the Hebrews, the Passover and the Feast of Tabernacles, lasted each seven days, and between

Passover and the Festival of Weeks (Pentecost) was an interval of seven weeks. The seventh year was a sabbatical year; the year following seven weeks of years was the year of jubilee. In the New Testament occur many groups of seven. In the Revelation (Apocalypse) alone, there are seven churches of Asia, seven stars, seven trumpets, seven spirits, seven horns, and seven eyes of the lamb. Among the Greeks the number seven was sacred to Apollo, and the Pythagoreans gave it a conspicuous place in their theories. The sacraments of the Roman Catholic Church are seven in number, and so are the orders of the ministry in the same church, there being four minor and three major or sacred orders. The number seven also has special significance in the religions of India, Hinduism and Buddhism. Various reasons have been given for the peculiar regard had for this number, such as that seven is a symbol of completeness, compounded as it is of three and four, perfect numbers, representable in space by the triangle and the square.

SEVEN AGAINST THEBES. See ETEOCLES AND POLYNICES.

SEVEN CHAMPIONS OF CHRISTENDOM, The, a romance of chivalry, by Richard Johnson, entered on the *Stationers' Register* in 1596. A second part appeared in 1608 and a third in 1616. In it are recounted the exploits of St. George of England, St. Denis of France, St. James of Spain, St. Anthony of Italy, St. Andrew of Scotland, St. Patrick of Ireland, and St. David of Wales.

SEVEN CHURCHES OF ASIA, a collective name applied in the Bible, in Revelation 1-2 (Apocalypse 1-2), to the churches of Ephesus, Smyrna, Pergamum, Thyatira, Sardis, Philadelphia, and Laodicea. There appear before St. John seven candlesticks, in the midst of which stands Christ, holding seven stars. Christ tells St. John that the seven stars are the angels of the seven churches, and that the seven candlesticks are the seven churches. He instructs the saint to write to the angels, and tells him what to write to each. The messages are brief exhortations to the followers of Christ which praise steadfastness and admonish against inconstancy.

SEVEN CITIES, Island of the, a fabulous Atlantic isle believed in the 14th and 15th centuries to have been settled by seven bishops and their followers expelled from Spain by the Moors in the 8th century. It may have been a late medieval revival of the classic Atlantis and Fortunate Isles myths.

SEVEN DAYS' BATTLES, a series of engagements fought near Richmond, Va., during the week of June 26–July 2, 1862, concluding the Peninsula Campaign of the American Civil War. Gen. George B. McClellan of the Union Army was on the Chickahominy River, only a few miles from Richmond, with 92,500 men. Gen. Robert E. Lee, the Confederate commander, was defending the city with 80,762 troops, including Stonewall Jackson's command, which had been brought up from the Shenandoah Valley. McClellan attempted to resume his advance on June 25, and an indecisive battle at Oak Grove resulted. Then Lee determined to seize the initiative. His plan was to turn McClellan's right flank and thus end the threat to the Confederate capital. To this end he sent Stonewall Jackson against McClellan's right from one direction, while he himself attacked from another. He threw three strong divisions led by Ambrose Powell Hill, James Longstreet, and Daniel Harvey Hill across the Chickahominy to cooperate with Jackson, and without waiting for him to arrive, attacked Gen. George Archibald McCall's division of Pennsylvania Reserves at Mechanicsville and Beaver Dam Creek, and was finally repulsed with great loss. On the 27th, McCall was withdrawn, Jackson made connection with Lee, and the combined Confederate forces attacked Fitz-John Porter's corps and McCall's division, later reinforced by Henry Warner Slocum's division, at Gaines' Mill (q.v.), the result being a bad defeat for the Union forces; Lee's losses, however, in killed and wounded, were about double those of Porter.

Porter retreated across the Chickahominy, and McClellan started on his retreat, or change of base, to James River. Lee pursued and on the 29th fought the two battles of Peach Orchard and Savage Station, both of which were drawn battles, although in both cases the Union troops withdrew from the field to continue the retreat which they had successfully covered. On the 30th, part of the Union Army and nearly all of Lee's army fought the bloody Battle of Frayser's Farm (q.v.), the Union forces holding the ground until after dark covering the passage of the trains, and defeating all of Lee's persistent efforts to break and destroy it. The last of the Seven Days' Battles was fought at Malvern Hill (q.v.), July 1, resulting in a bloody repulse for Lee. That night the Army of the Potomac withdrew to Harrison's Landing on the James River.

According to General Longstreet, General Lee's plans in the Seven Days' Battle were excellent, but were poorly executed, and in an official report, General Lee remarked that "under ordinary circumstances the Federal Army should have been destroyed." That it was not destroyed is due to the skill of McClellan in conducting the retreat and even more to the fighting quality of his subordinate officers and their men. See also PENINSULA CAMPAIGN OF 1862, THE.

SEVEN HUNTERS, The. See FLANNAN ISLANDS.

SEVEN LAMPS OF ARCHITECTURE, The, a treatise on architecture by John Ruskin, published in 1849. In this book architecture is regarded as the revealing medium or lamp, through which flame a people's passions and which embodies their life, history, and religious faith, in temple, palace, and home. The first lamp is Sacrifice, next comes the Lamp of Truth, the third and fourth lamps are those of Power and Beauty. The fifth is the Lamp of Life, and the last two lamps are those of Memory and Obedience. Ruskin affirms that "the architecture of a nation is great only when it is universal and established in its language, and when provincial differences in style are nothing more than so many dialects." His championship of the Gothic style as the greatest of all architectural creations contributed to the Gothic revival of his day.

SEVEN PILLARS OF WISDOM, Thomas Edward Lawrence's narrative of the Arab revolt against the Turks in World War I, which revolt led to the establishment of the present Arab nations. The book was rewritten three times in the years following the war. A few trial copies were

privately printed in 1922, and a larger subscription edition, in 1926. In 1927, somewhat less than half the text was commercially published in Britain and the United States as *Revolt in the Desert*. The whole work was not issued for general circulation until 1935.

Early in the war, Lawrence was serving with the British army in Egypt. When the Arab revolt broke out, his knowledge of the people and their language, acquired during prewar years as an archaeologist, made him a logical choice as liaison officer between the rebels and the British. After meeting the leaders, Lawrence decided that Prince Feisal, son of the Sherif of Mecca, was the most competent of the chieftains. From then onward, Lawrence worked with Feisal, furnishing most of the long-range planning of the campaigns. His most brilliant contribution to strategy came with the realization that Arab weakness in matériel and formal military discipline could be exploited as an asset, by avoiding pitched battles and harassing the Turks by constant swift guerrilla raids against their communications. The Turks were allowed to hold, at great cost, their fortified posts; the rest of the country belonged to the Arabs. The capture of Akaba, July 6, 1917, freed the entire Hejaz except for the beleaguered Turkish garrison in Medina. Thereafter, the war shifted steadily northward, till the Arabs formed the right wing of Field Marshal Edmund Allenby's victorious advance in September 1918. With the capture of Damascus, Oct. 1, 1918, Lawrence's part in the war ended.

The Seven Pillars of Wisdom is a great narrative of warfare and adventure pursued to the utmost of human endurance; it is also a revelation of one of the most remarkable characters of modern times. Lawrence took pride in making himself as hardy as the Arabs whom he led, and acquired their fatalistic contempt for pain and death. He emerges from these pages as a man of cold, penetrating intellect: a crusader, fired by loyalty to the cause and the men to whom he had pledged his word, and a child of the 20th century in his tortured doubts of himself and his cause.

DeLancey Ferguson.

SEVEN PINES, Battle of. See Fair Oaks (Seven Pines), Battle of.

SEVEN SAGES, in ancient Greece, the collective designation of seven ancient philosophers and sages. According to a commonly accepted listing, they were Solon of Athens, Thales of Miletus, Pittacus of Mitylene, Bias of Priene, Chilon of Sparta, Cleobulus of Lindus, and Periander of Corinth. They all lived between 620 and 548 B.C.

SEVEN SEAS, The, a collection of verse by Rudyard Kipling, containing several of the author's most vigorous and characteristic poems, originally published as a separate volume in November 1896. It has also been included, under the same name as a subtitle, in a larger and more comprehensive collection, entitled *Verses*.

While *The Seven Seas* is not limited in range, containing, as it does, poems on many themes—virile songs in stirring rhythms, such as *The Last Chantey*, striking character portraits like that of the grim old shipowner of *The Mary Gloster* and of "the dour Scots engineer" of *McAndrew's Hymn* and *The Last Rhyme of True Thomas* and other lyrics and ballads of a high order—still, the dominant note, sounded especially in *A Song of the English*, is a fervent, almost religious belief in Britain's world supremacy—what Paul Elmer More calls the poet's "earnest conviction that the English race, 'the Sons of the Blood,' are destined to sweep over the earth and fulfill the law of order and civilization." It was this note that caused the poet to be hailed the unofficial laureate of the British Empire. Kipling's frequent use of colloquialisms and slang, however appropriate when his speakers are such careless folk as soldiers and sailors, have led some critics to disparage his claims to the laurel. Yet his eager revelation of the charm and beauty inherent in "things as they are," is precisely what endears him the most. As Charles Eliot Norton says: "The poet finds today as entertaining as any day that ever dawned, and man's life as interesting and as romantic as it ever was in old times. . . . It is enough now gratefully to recognize that he continues the succession of royal English poets, and to pay him the homage which is his due."

SEVEN SLEEPERS, a Christian legend widely disseminated in manuscripts throughout the Western and Oriental world, and even found in Mohammedan sources. The earliest preserved record of it is a Syriac text from the beginning of the 6th century. The story relates that during the persecution of the Christians under the emperor Decius (201–251), seven noble youths of Ephesus, having refused to worship pagan idols, concealed themselves in a nearby cavern, the entrance of which was closed by order of the emperor. The persecuted youths immediately fell into a deep slumber, from which they were accidentally awakened in the reign of Theodosius II (401–450), after the lapse of two centuries. The stone blocking the entrance to their retreat having been removed by a shepherd, one of their number went to the city to purchase bread. He was astonished to see the Christian cross erected in the city, and the citizens were confounded by his antiquated dress, obsolete dress, and old money which he offered in payment for bread. Suspected of having found a secret treasure, he was carried before a judge, to whom he related his miraculous story. The bishop of Ephesus, the magistrates, and even the emperor himself hastened to the cave and found the sleepers still bearing the bloom of youth. Before they expired, one of them explained to the emperor that God had caused them to fall asleep in order to demonstrate the proof of the resurrection.

SEVEN WEEKS' WAR, the Austro-Prussian War of 1866, provoked by the German foreign minister, Otto von Bismarck, in order to establish Prussian political supremacy over the German people, and precipitated by the Schleswig-Holstein controversy (see Bismarck, Prince Otto von). Prussia was supported by Italy, while Austria's allies included Bavaria, Württemberg, Saxony, Hanover, Baden, and other smaller German states. Under Count Helmuth von Moltke, the Prussians won victories in rapid succession, outfighting the Austrians in every skirmish, and defeated them decisively at the Battle of Königgrätz, or Sadowa, on July 3, after about seven weeks of actual fighting. The negotiations at Nikolsburg (July 26) were confirmed by the Peace of Prague (Aug. 23) and subsequent acts of formal settlement. Prussia then established and dominated the North German Confederation, which, after the Franco-Prussian War, paved the way for empire (1871).

SEVEN WONDERS OF THE WORLD, a selection of seven ancient works of art and archi-

tecture regarded by the Greek and Roman world of the Alexandrian epoch and later as awe-inspiring, and pre-eminent in size or splendor. An opuscule entitled *De septem orbis miraculis*, attributed to Philo of Byzantium, gives one listing of the seven; a variant is offered by Antipater of Sidon. According to the most popular tradition they were: (1) the pyramids of Egypt; (2) the hanging gardens of Semiramis and the walls of Babylon; (3) the statue of the Olympian Zeus by Phidias, at Olympia; (4) the Colossus of Rhodes; (5) the temple of Artemis at Ephesus; (6) the Mausoleum erected by Queen Artemesia at Halicarnassus; and (7) the Pharos (lighthouse) of Alexandria. Of these only the Pyramids have survived.

Pyramids.—Situated on the Nile's west bank above Cairo, the pyramids were erected in the period 3000–1800 B.C. by Egyptian monarchs to serve as their tombs. Of some 70 known pyramids the earliest example is that of King Zoser at Saqqara; reputedly designed by the royal physician Imhotep (q.v.), it is a step pyramid with five terraces. The largest are those at Giza, built for pharaohs of the Old Kingdom: Khufu (Cheops), Khafre (Chephren), and Menkure (Menkaure; Mycerinus). The first of these, called the Great Pyramid because the largest, measured originally 755 feet square at the base, towered 481 feet high, and covered an area of nearly 13 acres. It has been estimated that a labor force of about 100,000 men required 20 years to complete it.

Pyramids of Egypt.

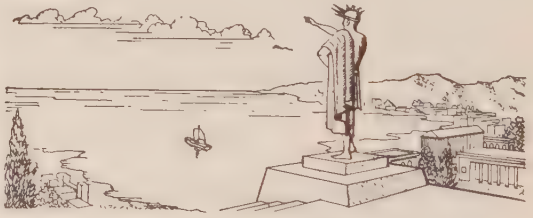
Hanging Gardens and Walls of Babylon.—Both the city walls and the hanging gardens which Greek travelers found so impressive were of the "new" city erected subsequent to Sennacherib's destruction of Babylon in 689 B.C. The Chaldean kings, Nabopolassar (r. 626–605) and his son Nebuchadnezzar II (r. 605–562) were builders of the mighty walls described by Herodotus and Ctesias in the 5th century B.C. Herodotus ignores the hanging gardens; other writers describe them as a series of terraces rising along the Euphrates bank and connected by marble stairways. Planted with a profusion of trees, shrubs, and flowers, the gardens were watered by fountains fed through pipes from cisterns in the topmost terrace. Nebuchadnezzar had the world's most celebrated gardens developed as an adjunct of his palace; but the Greeks ascribed them to Semiramis, a legendary queen of Babylon, daughter of the goddess Derceto.

Hanging gardens of Babylon.

Statue of Zeus by Phidias.—Like the Athena statue for the Parthenon, Phidias' colossal statue of Zeus was a chryselephantine work, the flesh parts of ivory on a wood or stone core, the drapery and other ornaments of gold. The sculptor represented the god crowned with an olive wreath and seated on a cedarwood throne which was adorned with gold, ivory, ebony, and precious stones. In his right hand Zeus held an ivory and gold statue of Victory, in his left a scepter surmounted by an eagle. The statue was placed in the great temple of Zeus in the sacred grove at Olympia (completed in 457 B.C.) and nearly attained the room's 60-foot roof. The Emperor Theodorus I removed it to Constantinople where it was destroyed in a fire in 475 A.D.

Statue of the Olympian Zeus by Phidias.

Colossus of Rhodes.—A popular name for the statue of the Sun designed by Chares of Lindus and erected overlooking the harbor of Rhodes. It required 12 years to build (292–280 B.C.), but survived only 56 years, being overthrown and broken to pieces by an earthquake in 224 B.C. The statue was upward of 105 feet tall. It is said that the fragments remained *in situ* for 896 years until a Moslem general, in 672 A.D., sold them to a Jew of Emesa.



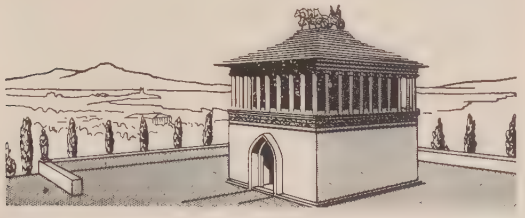
Colossus of Rhodes.

Temple of Artemis.—The famous temple dedicated to Artemis at Ephesus, chief of the 12 Ionian cities in Asia Minor, was designed and built by the architect Chersiphron in the 6th century B.C., Croesus contributing to the building fund. Burned down by Herostratus in 356 B.C., it was rebuilt by the joint efforts of all the Ionian states. It was again destroyed when the Goths sacked the city in 262 A.D. Fragments of the columns of the original temple are in the British Museum.

Temple of Artemis at Ephesus.

Mausoleum at Halicarnassus.—After the death in 353 B.C. of Mausolus, king of Caria in Asia Minor, his widow, Queen Artemisia, determined to commemorate him with the most costly

memorial. The structure, designed by Pythius and adorned by sculptures of Scopas and Praxiteles, was destroyed by an earthquake before the 15th century.



Mausoleum erected by Queen Artemisia at Halicarnassus.

Pharos of Alexandria.—Erected about 270 B.C. in the reign of Ptolemy II Philadelphus on an islet off the harbor of Alexandria, this lighthouse was the prototype of all the similar structures built on the coasts of the Roman Empire.

Pharos of Alexandria.

SEVEN YEARS' WAR, a war between Prussia and other European powers (1756–63). By the treaties of peace concluded at Breslau 28 July 1742, and at Dresden 25 Dec. 1745, Maria Theresa of Austria ceded to King Frederick II six principalities of Silesia and the county of Glatz. In the hope of recovering them she concluded an alliance with Elizabeth, empress of Russia, brought over to her cause the king of Poland and elector of Saxony, Augustus III, and attempted to form a closer union with France. Meanwhile a dispute had arisen between Great Britain and France relating to their American boundary, and it broke out in 1755 into open hostilities. The king of England concluded an alliance with Prussia; and some months after France made a league with the court of Vienna. All the proceedings of the Russian, Austrian and Saxon courts were discovered to Frederick, who resolved to anticipate his enemies. In August 1756, he invaded Saxony, occupied the capital, which had been deserted by the court, Leipzig, Wittenberg and Dresden; took possession of the documents necessary to justify his conduct which he found in the archives of the cabinet in the last city, and invested the Saxon army in their fortified camp at Pirna. Meanwhile Field-Marshal Browne advanced from Bohemia with an army to liberate Saxony; but Frederick was able to check his advance, and the Saxons, 14,000 strong, were forced to surrender 15 October. The inferior officers and common soldiers were compelled to enter the Prussian service; but they soon deserted, making their escape to Poland, where the Saxon court resided during the whole war. Such was the end of the first campaign, and the Prussians remained through the winter in Saxony and Silesia. Frederick's invasion of Saxony was pronounced to be a violation of the Treaty of Westphalia, and France, as one of the guarantors of that treaty, now took part in the struggle. Sweden and Russia adopted a similar course. In the diet at Ratisbon, held in January 1757, war was also declared on the part of the empire against Prussia.

Thus in 1757 Austria, Russia, France, Sweden and the German empire were in arms against Frederick, while he had no ally but England and a few German states (Brunswick, Hesse-Cassel and Gotha, besides, of course, Hanover). In order to be again beforehand with his enemies, Frederick (April 1757) marched into Bohemia, and on the 6th of May a bloody battle was fought at Prague, in which the Prussians conquered, but lost their distinguished general, Schwerin. The greatest part of the vanquished Austrian army threw itself into the city of Prague, to which the king immediately laid siege. But the defeat of Frederick by the Austrians under Daun, at Kollin, in the following month, 18 June, deprived the former of all his advantages. He was forced to raise the siege of Prague, and to retreat to Saxony and Lusatia. Little more than a month later, 26 July, the Duke of Cumberland, commanding the German allies of Frederick, was defeated at Hastenbeck on the Weser, in the south of Hanover, by the more numerous army of the French; whereupon the victors made preparations for taking up winter quarters with the imperial army in Saxony. The two armies had already united and advanced as far as the Saale, the French under the command of the incapable Prince Soubise, a favorite of the Marquise de Pompadour, when Frederick marched against them, and fought at Rossbach, a village between Merseburg and Weissenfels, that memorable battle, in which both the French and the imperial armies were defeated, and found safety only in a hasty flight 5 November. The defeated armies retired into winter quarters at a distance, and the possession of Saxony was secured to the king. Upon this Frederick hurried back to Silesia, which was now occupied by the Austrians. With a small army, fatigued with a long march, he defeated at Leuthen a force twice as great, under Daun, 5 December. By this victory Frederick recovered Silesia, and he was now more formidable to his foes than ever; for not only had he been victorious himself, but while he had been thus occupied in the south and west his general Lehwald had successfully repelled the Swedes and Russians on the north and east.

The third campaign was opened in February 1758, by Ferdinand, Duke of Brunswick, who was now at the head of the allied armies, in the place of the Duke of Cumberland, and opposed the French in Lower Saxony and Westphalia. His nephew, the hereditary prince, afterward Duke of Brunswick, Charles William Ferdinand, commanded under him. Duke Ferdinand made himself master of the Weser, expelled the French, under Clermont, from Lower Saxony and Westphalia, and defeated them 23 June at Krefeld. He then returned over the Rhine to Hesse, where Soubise was stationed with a French army, and whither Clermont followed him. Ferdinand, in the meanwhile strengthened by 12,000 British troops, forced the two hostile bodies to retire over the Main and the Rhine, where they went into winter quarters. Mean-

while the Russians, under Bestucheff, had advanced as far as the Oder; and subsequently Fermor, who superseded Bestucheff, occupied east Prussia, and then moved into Brandenburg, spreading devastation on his way. At this juncture Frederick made a masterly march to the Oder, and toward the end of August engaged the Russians at Zorndorf, in the north of Brandenburg, where he gained a sanguinary victory, which forced the Russians to retreat to Poland. After this he again turned his attention to Saxony, where his brother Prince Henry was no longer able to resist the Austrians. He encamped at Hochkirch, but here he was surprised by Daun in the night of 14 October and suffered a total defeat. He nevertheless succeeded with the remains of his army in effecting a junction with his brother, after which he again drove the enemy out of Silesia and Saxony. At the close of the campaign the king saw all his dominions except Prussia proper free from the enemy. In France there was a general wish for peace; but Louis XV and his mistress, the Marchioness de Pompadour, were bent on continuing the war. A new alliance was therefore concluded with Austria 30 Dec. 1758. Frederick, however, had also obtained a new treaty with Great Britain, which promised him a large yearly subsidy. Yet he determined in the coming campaign to act with his main army as much as possible on the defensive and to commit aggressive movements to detached corps.

The campaign was opened in March 1759, Prince Henry marching into Bohemia, where he dispersed the hostile forces, and captured immense quantities of military stores. He then entered Franconia, and put the inactive imperial forces to flight. At the same time the Prussian general Dohna drove back the Swedes once more to Stralsund, and managed to keep the Russians for a time in check. But when the Russians pressed forward in ever-increasing numbers under Soltikoff, Dohna found himself obliged to give way. Frederick then gave his command to General Wedel, who received orders to prevent the junction between the Russians and Austrians at all costs, and accordingly on 23 July attacked the Russians at Kay, near Züllichau, in the east of Brandenburg. His attack was unsuccessful, and the Russians after their victory advanced to Frankfort-on-the-Oder. Frederick now hastened in person to his electoral dominions, and on 12 August attacked the Russians at Kunersdorf, near Frankfort, and had already defeated them when the victory was snatched from him by the Austrians, under Laudon, who inflicted on him a defeat such as he had never before sustained. The Russians purchased their victory dearly, and they made no use of it. Yet Frederick's position was extremely dangerous; indeed, he began to apprehend an unfortunate issue of the war. The Russians were victorious in his hereditary states; Daun was in Lusatia with a large army, and Saxony was overrun by the imperial troops. The Austrians and Russians wished to unite, but Prince Henry deprived the former of their magazines, and thus obliged them to retreat; and Frederick anticipated the Russians in their march to Silesia, and compelled them to retire to Poland. In the west Frederick's allies had been more successful. They had, indeed, been able to do but little at the beginning of the campaign. The French had taken Frankfort-on-the-Main by surprise during the winter, and the plan for recovering the city was frustrated by the failure of the attack on Bergen 13 April. But 1 August, Ferdinand gained a decisive victory at Minden over the French troops under Contades and Broglio. On the same day the hereditary Prince of Brunswick likewise defeated the French at Gohfeld, and they were driven over the Lahn on one side and over the Rhine on the other. The Swedes also, who, after the battle of Kunersdorf, when Prussian Pomerania was destitute of troops, invaded that country, were driven by Manteuffel and Platen under the cannon of Stralsund. Thus, in spite of all his mishaps, Frederick's fortunes were still in the ascendant at the end of the campaign.

The campaign of 1760 seemed at first to forbode ill success to Frederick. While he himself was engaged in Saxony, the brave General Fouqué suffered a defeat in Silesia, in consequence of which the Austrians occupied the whole land. Frederick thereupon gave up Saxony in order to recover Silesia. With 30,000 Prussians he marched into that province, and intrenched himself at Liegnitz. Here on 15 August he defeated Laudon, and thereby effected his purpose of recovering Silesia, but he was unable to prevent Austrian and Russian troops from breaking into Brandenburg and laying waste his hereditary dominions. Frederick hastened thither to cut off the enemy, but not finding them there he returned to Saxony, where the imperial forces were stationed, and Daun and Lascy had united. At Torgau, on the Elbe, he attacked the enemy 3 November, defeated them in a bloody engagement, and then went into winter quarters in Saxony. The Russians were also forced to raise the siege of Colberg and to retire to Poland. The allied forces, under Ferdinand of Brunswick, defeated the French 31 July at Marburg; but the latter remained in Hesse.

In the opening of the next campaign 11 Feb. 1761 Ferdinand attacked the French in their quarters; they fled, losing many of their fortifications and magazines. A corps of French and Saxon troops was defeated 14 February at Langensalza: but the allies were obliged to raise the siege of Ziegenhain, Marburg and Cassel with loss, and the French once more became masters of all Hesse, and had an unobstructed passage to Hanover. The proposals of peace now made by Britain and Prussia were not accepted, and Frederick endeavored to protect Silesia against the Austrians and Russians, who had united in August at Striegau. He and his allies, however, met with reverses at Schweidnitz, Colberg and elsewhere, and despite some successes (as at Villingshausen) Frederick felt himself in a desperate condition. But at the very time when Frederick's distress was greatest, Elizabeth, the empress of Russia, died 5 Jan. 1762, and her successor, Peter III, concluded with him 5 May the Peace of Saint Petersburg. Sweden likewise made peace with Prussia, and the Russian emperor sent a body of troops to aid the Prussians. But the emperor's early death broke the alliance with Frederick, and his successor, Catharine II, recalled the Russian troops from the Prussian service. Frederick, however, was delivered from one dangerous enemy, and had gained an important preponderance of strength over the rest. After recovering Schweidnitz and providing for the defense

of Silesia, he marched to Saxony. On October 29, an important victory was won over the Austrian and imperial forces at Freiberg, and the king now concluded an armistice with the Austrians, although it related only to Saxony and Silesia. Under Duke Ferdinand of Brunswick, the allies then began the campaign of 1762 against the French; the latter were defeated on June 24 at Wilhelmsthal and driven from their fortified camp at Kassel. Two days later at Fontainebleau the preliminaries of peace between Britain and France were signed, and the peace itself was confirmed at Paris on Feb. 10, 1763. After a short negotiation Frederick concluded a peace with Austria and Saxony at Hubertusburg, Feb. 15, 1863, by which each power received again all the territories that it had possessed before the war. The simultaneous struggle between Great Britain and France in North America—the French and Indian War—and in India ended with the decisive victory of the former, and with France losing almost all her North American and Indian territory.

SEVENTEEN-YEAR LOCUST. See CICADA.

SEVENTEENTH CENTURY. In the first half of the 16th century, Lutheranism had firmly entrenched itself in northern Germany and had spread to the Scandinavian countries so that the Baltic had become almost a Lutheran lake. In the second half of the same century, a group of interconnected conflicts in the neighborhood of the English Channel had failed to bring about the suppression of Calvinism in Great Britain, Holland, and France. From 1576, and more particularly from 1594, Catholicism in Germany had passed to the counteroffensive, and here its conflict was against aggressive Calvinism, while the Lutherans were becoming a conservative interest, anxious for peace.

When the 17th century opened, the forces of the Reformation and the Counter Reformation (qq.v.) seemed to be gathering themselves for a final struggle in Germany, where imperial authority was in eclipse and imperial institutions were now failing to function. The whole balance of the Continent was in question, for a small margin seemed likely to decide whether the Austrian Habsburgs should lose their imperial position or should reassert their authority and combine with the Spanish Habsburgs to dominate Christendom. From the beginning of the 17th century, therefore, western Europe lay under the shadow of a great war. Plans for the establishment of perpetual peace symptomized the growing nervousness and combined with the "appeasement" policy of the Lutherans and of James I of England to give evidence of the horror which war inspired. Proposals for the reunion of Protestants and Catholics were brought out under the shadow of war by Hugo Grotius in Holland, for example, and later by John Dury in England.

Thirty Years' War.—The Austrian Habsburgs were in decline at the opening of the century, but during the first decade they were planning to rescue their dynasty, and during the second decade the plans were being put into effect. In 1597 the Counter Reformation had opened a remarkable new attack in Styria, and the Protestants, who had seemed to be consolidating their victories in the neighboring Habsburg territories, soon saw that they must be prepared to face actual warfare unless they were content to be put into definite retreat.

Beginning in Bohemia, extending to Germany, and moving thence into the region of the Baltic from 1624, the Thirty Years' War (1618–1648) brought the religious conflict in Europe to a climax and raised issues which were bound to affect the fate of the entire West. It gathered into itself all the regional controversies, local disputes, and international rivalries of Christendom, and became a more general war than any which had preceded it. As long as the Habsburgs went on winning successes in the course of the struggle, their victory at each successive stage only had the effect of bringing into the conflict a new enemy, whose security seemed threatened by their latest advance. Fortunately the Ottoman Porte was unable to take advantage of the distracted condition of the Christian countries in this period. The West made such marked improvements in military science during the course of the war that it proved decidedly superior to the East when the Turkish attacks were renewed in the latter half of the century.

The results of the war were: firstly, the rise of a vast Swedish Empire, which went on expanding during most of the century until it comprised almost all the coast of the Baltic; secondly, the effective origin of the modern problem of Alsace-Lorraine and the passage of France from a defensive policy to that career of aggression which is associated with the reign of Louis XIV; and, thirdly, the eclipse of the Spanish Habsburgs (who had come near to the domination of Europe in the 1580's) and the further reduction of Habsburg imperial power in Germany, with the result that the Austrian branch of the dynasty concentrated its attention in the future on the consolidation of its group of Danubian territories. The Peace of Westphalia (q.v.), which concluded the war in 1648, was the first of the series of great international treaties which from that time have periodically established an order and a territorial arrangement in Europe after a war involving the entire Continent.

Role of Louis XIV.—Partly because the Spanish Habsburgs were in decline and Spain herself was economically undermined, partly also because the Austrian Habsburgs were distracted by the renewed attacks of the Ottoman Turks, the French monarchy under Louis XIV (r. 1643–1715) embarked on an aggressive course after 1661, until fear of its Continental ascendancy united many nations against it in 1688. As he developed his career of conquest, Louis would cleverly isolate his enemy, reducing to a minimum the need for direct military action; and the great development which he gave to the French

diplomatic system and the practice of diplomacy had a marked effect on other countries, so that this branch of governmental activity advanced to a new stage. Furthermore, in the conflict against the France of Louis XIV, European statesmen became more conscious than ever before of the principle of the balance of power, and more scientific in their application of it.

MONARCHY

The 17th century marks a critical period in the history of European monarchy, for that institution had to meet a serious challenge in most of the countries of the Continent, as well as in England. This is the period when, in many monarchies and principalities, the conflict between the ruler and the parliamentary systems—the diets or estates—came to a point of critical decision. As in England, the conflict often involved the question of the king's right to keep a standing army, and the right of the parliamentary estates to give or withhold their assent to taxation. Now, as at other periods, the needs of the government in time of war, and the growing burden of expense as the methods of warfare developed, had much to do with the development which was given to the structure of the modern state.

Position of the Assemblies.—In the various countries of Europe and in many of the principalities of Germany the diets or estates had long held the princely ruler more tightly imprisoned than the English Parliament had done; and the extremes to which this had been taken in Bohemia, Hungary, and other Habsburg territories had been from the start one of the main issues involved in the Thirty Years' War. On the Continent, however, the assertion of "historic rights" against the ruler represented the obstructiveness of a selfish and reactionary nobility which controlled the proceedings in the "parliamentary" assemblies. It was the prince who sought to save the peasantry from the tyranny of their local lords, and who represented the general welfare of society against the selfish private privileges of the nobility. It was the prince who more truly represented the community at large and tended to gain the support of the nonnoble classes. The whole general conflict has sometimes been described, therefore, as the struggle of "The State *versus* the Estates."

Even in the United Provinces the provincial estates, as they opposed the monarchical and centralizing tendencies of the House of Orange, were reactionary, defending a system of local autonomy and resisting the attempt to weld them into a state. Even in France, where the States General (q.v.) ceased to function after 1614, the Parlement of Paris, consciously attempting to imitate the procedures of the contemporary English Parliament, was in reality supporting ancient privilege and private rights which obstructed the work of government. The conflict of the Habsburgs with the Bohemian nobility until 1620, and with the Hungarian nobility throughout the century; the bitter struggle of many German princes (including the Hohenzollern ruler of Brandenburg-Prussia) against their respective systems of estates; the English Civil War and Commonwealth (1642–1660); the French *Fronde* (q.v.) in the period 1648–1654; the "republican" regime of Jan De Witt in Holland, 1653–1672; and the ascendancy of the nobles in Denmark and Sweden —all these illustrate the vicissitudes of the institution of monarchy, particularly towards the middle of the 17th century. The rebellion of Portugal against Spain in 1640 and the great rising of Catalonia in the same year raised similar questions of principle; and the sufferings caused by the Thirty Years' War produced repeated further insurrections on the part of a hungry peasantry, as, for example, the rebellions in Sicily and Naples in 1647–1648.

The Forms of Monarchy.—The necessities of war and the requirements of internal order, however, showed that monarchical authority was still indispensable. Most of all there was need for an authority which should support the general welfare of society against nobles who refused to regard themselves as subjects, and against sectional groups which refused to bow to the authority of government. In France, where the king had sometimes acted as though he were merely the most privileged of the vested interests of the country, using his power to support one faction against another and sharing out the spoils amongst his favorites, Cardinal Richelieu (1585–1642) taught the monarch a higher, superintending role, separating his conduct in his private life from his function as the personification of the idea of the state. From 1661, Louis XIV brought this conception of monarchy to its climax and turned it into a work of art, making himself at any rate the greatest "actor of majesty" that Europe had ever seen. Neither Louis nor the monarchs of the next generation succeeded, however, in making the further distinction between the dynastic interests of the royal family and the interests of the body politic as such. The Restoration of 1660 in England; the establishment of the most extreme royal absolutism in Denmark in 1660–1665; the revival of the authority of the House of Orange in Holland, especially from 1672; the victory of the Hohenzollern dynasty over the estates in Brandenburg-Prussia (as in 1663 and 1667); and the triumph of the royal power in Sweden in 1680–1682, signalize the recovery of the principle of monarchy, and the restoration of internal stability in the countries of western Europe.

In certain regions—for example, in Mecklenburg, in Poland, and to a considerable degree in Hungary—the monarch failed in the attempt to discipline the nobles into the modern idea of the state. In other regions—particularly in Brandenburg-Prussia and in the Russia of Peter the Great (r. 1682–1725)—the ruler succeeded in turning the nobles into "servants of the state," but only by conniving with them in their oppression of the other classes of society, and by giving them governmental authority on their own estates. In these countries there developed on the basis of military needs a secular, utilitarian type of monarchy, more ruthless in its methods than the religious monarchy of Louis XIV. In general the peasantry and the townsmen to the east of the Elbe River suffered in the 17th century a continuation of that decline which had been taking place in the 16th century, so that their position and prospects were worse than they had been in medieval times.

ARTISTIC, INTELLECTUAL, AND RELIGIOUS LIFE

The Baroque.—The development of a "Catholic Renaissance" in France, the achievements of Catholic missionaries in all parts of the world, the wide establishment of the Jesuit order, and the victories of Count Tilly and Albrecht von

Wallenstein in the early stages of the Thirty Years' War all contributed to a feeling of exultation in Rome at the time when the new Basilica of St. Peter's, the "greatest architectural wonder of the world," had at last been completed. St. Peter's was consecrated in 1626 and remained the real center of artistic activity in Rome throughout the century. During the pontificate of Urban VIII (r. 1623–1644), as well as during the reigns of his two successors, Rome was turned into a baroque city, chiefly under the inspiration of the sculptor and architect Lorenzo Bernini (1598–1680) and the painter Pietro da Cortona (1596–1669), and the new style impressed its character on the city more profoundly than any previous one had done.

The baroque style, greatly patronized by the Jesuits, seemed to express the exuberance of the Counter Reformation, and it dominated European art for at least a century, spreading from Rome to Spain, Portugal, Austria, Catholic Germany, and Poland, although it had less influence in France and England. It was a dynamic style, seeking dramatic effects, and loading churches with ornament and gilding, colored sculptures, and sensuous curves. Behind it was a spirit which seems to have affected painting and poetry, giving therefore a certain unified character to the culture of the time.

Northern Cultural Leadership.—Culturally, the 17th century saw the end of the long period of Mediterranean leadership. In the closing decades of the century the remarkable advances that changed the character of Western civilization were centered about the English Channel. At the beginning of the century Spain was still enjoying her "Golden Age" in literature and the arts and even science, an age of great originality and of riotous individualism. The influence of Spain was quickly transmitted to the countries of western Europe, and had its part in the development of the famous culture of Versailles, the flowering of the arts in the reign of Louis XIV of France. At the beginning of the 17th century the genius of Galileo illustrated the important part still played by Italy in the world of science. In the second quarter of the century, Holland came into her "Golden Age" with a burgher culture which blossomed in literature and art, as well as in technology, so that she acquired an ascendancy particularly in the Protestant world and greatly influenced England, for example, and governments such as that of the Great Elector in Brandenburg-Prussia. The most remarkable transition in the history of Western civilization for over a thousand years, however, took place in the last quarter of the 17th century, at a time when the English, the Dutch, and the French—especially the French Huguenots—were bound together by a close system of intercommunications. They were building up a culture vastly different from that of the Renaissance or that of 17th century Spain or that of Louis XIV's court of Versailles. At this point in the story the success of the Scientific Revolution coincides with the palpable appearance of what we today would call the modern world.

The Scientific Revolution.—It would be proper to regard most of the 17th century as still medieval, for it represented a world and an outlook packed with what we should call archaisms. At its opening men still pictured the physical universe in general in the way they had been doing for a number of centuries. The Renaissance itself had had the effect of making all branches of thought more subservient to ancient Greece than had previously been the case. During most of the century, Scholasticism still prevailed in the universities and had sway even in the Protestant world. During most of the century, Aristotle was still the master in natural science, where the ancient syntheses and the ancient modes of explanation were still current.

A new star and a new comet in the later decades of the 16th century had shaken the bases of the ancient astronomy and made it difficult to believe that the planets were attached to crystalline spheres. The consideration of the problem of projectiles had created a similar disturbance in the ancient science of mechanics; for it was difficult to reconcile the behavior of cannon balls with the basic assumption of that science, the assumption that a body could not keep in motion unless its original mover kept on pushing it. These two fundamental problems in astronomy and mechanics became like levers which dislodged an ancient universe and installed a new one, transforming the methods of science and revolutionizing human society. But first there was a period in which the bases of science itself had to be completely re-examined, and the whole question of scientific method was overhauled in the work of Galileo Galilei (1564–1642), in the writings (published 1604–1629) of Sir Francis Bacon (1561–1626), and in the *Discourse on Method* (1637) by René Descartes (1596–1650).

A chain of inquirers from the time of Galileo and Johannes Kepler (1571–1630) pursued the crucial problems in astronomy and mechanics and gradually disengaged the problem of gravitation, until in the 1670's a host of scientists in both England and France were touching the fringes of the final synthesis and bringing the scientific movement to its most exhilarating period. Galileo's way of mathematizing a problem and producing a formula had been geared to a more economical and strategic use of the experimental method. The effects of gravity, the path of falling bodies, the orbits of the planets, the pull of the stone on the sling that swirls it round, the irregularities in the movements of the planets as they came into proximity with one another, the more accurate measurement of celestial distances—these were the homely elemental problems that were being studied, and the results of earlier work on them were being refined and correlated.

The century had seen various attempts to create vast mythical "systems of the universe" which were born out of high flights of philosophical speculation; but a humbler approach to the problem of nature now produced such results in its treatment of a few pivotal points as to revolutionize man's picture of the universe and change forever his views about the way in which the problems of the physical world should be tackled. One imagined the moon being attracted to the earth like a falling apple; but, if such were the case, why did it not drop completely into the earth? If, however, one imagined the moon as a stone swirling round the earth in an invisible sling, one could then ask whether the tendency of the moon to fall into the earth might not exactly counteract the tendency of the moon to press out of the sling, making a beeline into empty space.

It was Sir Isaac Newton (1642–1727) who worked out the correspondences, showed with what nicety the heavenly bodies were mathe-

matically balanced, and developed on these lines a vast synthesis which presented a new system of the skies. Mechanics and astronomy were fused into a comprehensive whole; things terrestrial and things celestial were now comprised in a single piece of explanation: one system of laws prevailed over the entire universe. For the first time science achieved a plausible and satisfactory explanation of a moving earth. For the first time the ideal to which so many of the 17th century scientists had been pressing—the ideal of a universe reduced to a species of clockwork—seemed within reach. The new developments in scientific method were vindicated. And in a single stroke Newton completed the overthrow of the authority of both the ancient world and the medieval.

If it was the concentration on two pivotal problems which set human thought on a new path, and if it was the development in mechanics and astronomy which changed the very character of natural science, other movements throughout the 17th century also helped to usher in a new scientific era. By 1600, Europe had at last appropriated and assimilated all that it had to learn from the scientific teaching of the ancient world. The 17th century saw the final example of the influence of ancient Greece; for the old atomic theory was not only revived but was given a form which made it tenable for Christians; and, as Bacon had predicted, it led to a more subtle feeling for the complexity of the internal structure of matter, it generated new types of hypothesis, and it facilitated the quest for a mechanistic explanation of natural phenomena.

The 17th century saw the development of the important elementary scientific instruments—the telescope, the microscope, the thermometer, the pendulum clock, the barometer, the air pump, followed by the blowpipe. Certain anatomical discoveries at different dates in Padua enable us to see how slow had been the transmission, establishment, and recognition of scientific discoveries in the 16th century. The development of the periodical press in the 17th century, the increased facilities for scientific correspondence, the foundation of scientific societies (which helped to finance experiments and to publish results), and the rise of public interest in the work of scientists transformed the whole system of scientific communication and greatly speeded up the European repercussions of work achieved in any locality. Technological needs, in such fields as shipbuilding, navigation, and hydraulics, gave a stimulus to many branches of inquiry.

If the universities resisted the new science a campaign was conducted against their ancient curriculum; other institutions provided centers for scientific research; and royalty patronized this work. Treatises were written in the vernacular and the appeal was made from the learned world to that new arbiter in the world of thought, the general reading public. Science was being popularized; for example, in 1686, the year before Newton's *Principia* transformed the system of the universe, Bernard Le Bovier de Fontenelle in France produced *The Plurality of Worlds*, a work which summed up the pre-Newtonian astronomy in a dialogue intended to be as diverting for fashionable ladies as the latest novel. The 17th century thus exhibited a great tidal rise of science, the effects of which were widely felt in the world at large.

Religion.—The medieval character of much of the 17th century is illustrated by the leading part which religion played in the culture and the politics of the age. This feature is apparent equally in the England of Archbishop William Laud and the England of Oliver Cromwell. Sometimes it appears more clearly after 1600 than in the previous 50 years, as in the case of the remarkable "Catholic Renaissance" in 17th century France. Under these conditions, political theory itself was generally conducted within the framework of ecclesiastical thought; and it is within such a framework that we have to consider Richelieu's doctrines of government as well as the conception of monarchy which was current in the France of Louis XIV. Also it was within such a framework that there emerged a conception of *raison d'état* which became significant in the 17th century.

Toleration, which in the 16th century had been not an ideal but rather a compromise—a recognized departure from the ideal, even sometimes a mere measure of *Realpolitik*—established itself more genuinely as a religious principle amongst some of the sects of the 17th century. It was only gradually, however, that even the various branches of Protestantism learned to tolerate one another. And if freedom came to be enlarged during the course of the 17th century this was partly due to war-weariness and the rise of religious indifference, and partly to the desire of rulers to retain or recruit populations for purposes of economic recovery.

Because it kept watch over the general mundane interests of society instead of merely behaving as the servant of one church against another, the state tended to emerge above the rival faiths and these latter tended to be viewed rather as mere parties within the state. The secular government increased its authority and emerged as the effective umpire or arbiter. The older idea of the nation as a religious society was giving way, as the century proceeded, to the modern conception of the secular state.

Christianity itself came into a state of unusual weakness in the closing decades of the 17th century, perhaps because the religious conflicts had been too bitter and the fanaticism had been too intense. The scientific movement had come to its climax in Sir Isaac Newton without making any essential breach with religion; but the traditional religious outlook, like the traditional university teaching, had tended to lose credit in the accompanying controversies. Christianity also lost one of its great incidental supports in the general overthrow of authority that occurred, the discrediting of the customary appeal to the teaching that had been handed down from the past.

Protestantism was better able to adapt itself to the new intellectual outlook than Catholicism; for even over a vast range of mundane matters independent of essential dogma the Catholic system had become more hardened in its tradition. But if the Catholics set their faces too firmly against the intellectual movements of the time, the Protestants sometimes made too swift an alliance with the essentially mechanistic outlook that the 17th century had been developing. When it recovered its power again, Protestantism itself was transformed, becoming the more liberal and rationalizing system which has been familiar in the more recent centuries, radically unlike the Protestantism of the 16th and much of the 17th century. Newton's achievement was to become

(against the wish of Newton himself) the basis for a completely mechanistic view of the universe; and it was to be of some moment that the churches at the end of the 17th century were not in the best condition for meeting the challenge of the new science.

SOCIAL AND ECONOMIC LIFE

Secularization and the New Bourgeoisie.—Partly for this reason, the transition to the modern world is marked by a widespread process of secularization in society, in politics, and in all the realms of thought. The Scientific Revolution assisted this process, for its apostles had long been claiming that the methods of the new science could be transferred not merely from physics to chemistry and biology, but from the natural to the human sciences—to history, anthropology, politics, economics, and comparative religion. Here, too, the teaching of the past now lost its authority amongst a wide reading public; while in France, Holland, and England more scientific forms of inquiry, more methodical reference to statistics, and a more systematic collection of information affected the conduct and even the machinery of government.

Before the end of the 17th century "the age of reason" had opened, the age of the French *philosophes* had begun. The results of the Scientific Revolution were being turned by literary minds into a new world view, a new attitude to life. Men were becoming aware that they now possessed a power of changing their environment, even those aspects of it which they had hitherto been disposed to regard as providentially ordained. And a world which had long believed that the Golden Age lay in the distant past and that human societies and civilizations suffered from a natural process of decline began to see a future that opened out to wider horizons and indefinite improvement. The transition to the idea of progress had begun.

The process of secularization covered a wider area than could be accounted for by the Scientific Revolution alone. It would seem to have been the natural accompaniment of the development of a more urbanized society in the countries around the English Channel. Not only in Holland, which saw the flowering of a burgher civilization, but also in England and in the France of Louis XIV, we see the bourgeoisie coming into the ascendancy in this period. This class produced that new arbiter in the world of thought, the general reading public, and the leaders of the scientific movement appealed from the learned world and the church to this new arbiter. It was the section of society least submissive to tradition, least ready to accept mystery or mystification, and most apt to follow a worldly minded common sense. To meet its needs, literary style, which had been so ornamental, was pruned into simplicity and directness, as the scientists wished and as the Royal Society of England had wanted.

Trade and Competition.—As at the time of the Renaissance, the region which held the cultural leadership and which decided the character of the succeeding age was also the region which was the most economically advanced. The expanding markets, provided partly by the New World and partly by the large-scale needs of greatly expanding armies, had given great stimulus to economic advance, and in Holland, England, and France the overseas trade now came to assume great proportions. Holland had taken the lead in the movement and for a time was the chief shipping, trading, manufacturing, and financial country in Europe. Amsterdam was the commercial and financial capital of the continent, the Dutch East India Company having been founded in 1602, and the famous Bank of Amsterdam in 1609. In 1636–1637 the tulip mania brought out in Holland that crisis of frenzied speculation to which England and France were moving by the end of the century, a crisis which a little later culminated in England in the South Sea Company and in France in the Mississippi Bubble (qq.v.). The closing decades of the 17th century saw bitter economic conflict between the three leading countries, England, Holland, and France; and it seemed that the wars of religion which had ended in 1648 were to be followed by wars of trade.

The Changing World.—The promoters of natural science throughout the century insisted on the utilitarian importance of science and on the possibilities of its practical application. Both in agriculture and in industry this led to a more methodical study of processes and materials, a closer concentration on the means by which technological progress could be achieved. What we call the Scientific Revolution of the 17th century and what we have often seen as the Agrarian Revolution and the Industrial Revolution of the 18th century, were in reality proceeding together in the period of 1601–1700. It is impossible to disentangle these strands of intellectual and social change or to say that any one of them would have reached the importance which it actually achieved if the others had not been proceeding at the same time.

In reality, though, it was not merely science and man's attitude to the world that were changing, but the world itself that was being transformed before man's eyes. A static environment which had looked much the same for thousands of years was now developing so quickly that the change was visible to the naked eye. Men began to see that they were living in a dynamic society. In Holland, England, and France, the developments in finance and speculation were altering the structure of the state itself; and we see this particularly in the great war of 1689–1697, between William III and Louis XIV, a war which was in part a conflict between financial systems.

Seventeenth Century Background (London 1934; New York 1953).

HERBERT BUTTERFIELD,
Professor of Modern History in the University of Cambridge.

PRINCIPAL EVENTS OF THE 17TH CENTURY

1607—Foundation of the colony of Virginia.
1609—Letter of Majesty concedes Bohemian religious privileges.
1610—Discovery of Hudson Bay.
1613—Advent of Romanov dynasty in Russia.
1618—Outbreak of Bohemian Revolt and Thirty Years' War; opening of Synod of Dort (Dordrecht).
1620—Pilgrim Fathers land in New England; Francis Bacon's *Novum Organum.*
1624—Cardinal Richelieu becomes first minister in France.
1629—Edict of Restitution confiscates ecclesiastical land acquired by Protestants and brings the Thirty Years' War to a climax.
1637—René Descartes' *Discourse on Method.*
1642—Opening of the Civil War in England.
1648—Treaty of Westphalia.
1649—Execution of Charles I.
1660—Restoration of Charles II. The tide turns in favor of monarchy in Europe.
1661—Beginning of Louis XIV's personal rule.
1683—Siege and relief of Vienna; the turning of the tide against the Turks.
1685—Revocation of the Edict of Nantes.
1687—Sir Isaac Newton's *Principia.*
1688—The Glorious Revolution in England.
1693—Establishment of the National Debt.
1700—Death of Charles II of Spain, leading to the War of the Spanish Succession; beginning of hostilities in the Great Northern War.

SEVENTH CENTURY. Of all periods of history the 7th century of the Christian era seems at first glance most to deserve being called the dark age. In western Europe the cultural achievements of the great transmitters of ancient learning in the 6th century were fading into intellectual sterility. Pope Gregory I the Great (r. 590–604) marked the transition in his apparent condemnation of the study of classical letters and his abject surrender to the miraculous. Although he revived the papal authority and asserted it *urbe et orbe,* the unity of Latin Christendom could still succumb, as the old Roman political unity had done already, to the particularism of the barbarian kingdoms. These Germanic kingdoms showed little promise of rebuilding the Pax Romana and its universal law and order. The Lombards (q.v.) having divided Italy were unable to make it whole again. In Gaul and southern Germany the Merovingian rulers of the Franks (q.v.) became "do-nothing kings" (*rois fainéants*), their kingdom almost in dissolution. Anglo-Saxon England was a congeries of kingdoms frequently at war with each other. Spain, a united kingdom under the Visigoths (q.v.), nonetheless suffered from internal weaknesses that were soon to bring destruction. In these circumstances the change, long since evident, toward an agrarian economy, society, and culture was proceeding toward completion, bringing to an end the urban civilization of antiquity.

If in the eastern Mediterranean world the Roman Empire had survived the first onslaughts of German tribes and Asiatic hordes, and under Justinian had enjoyed in the previous century a revival of power and cultural brilliance, it was now in the 7th century meeting with disaster. Under repeated attack from barbarian tribes of Slavs and Avars (qq.v.) in the Balkans, and from the more civilized peoples of western Asia, the empire (now Greek, Byzantine, as well as Roman) was almost continuously fighting for its life. The end of the Roman Empire and the ancient Mediterranean civilization seemed to be at hand.

Age of Transition.—Such a picture of gloom, however, is not a just representation of the century. Although a period of decline, the 7th century was also one of transition, of further change from the old to the new in the great and continuous process of history. It was, in fact, a time of political, religious, economic, and cultural movements of vital importance to the development of the ancient Mediterranean into the European civilization of the Middle Ages and the modern world. The Byzantine Empire, fighting valiantly for its life, not only survived—a notable success in such an age—but in surviving became the center from which Graeco-Roman culture and Greek Christianity spread later among the Slavic and Asiatic peoples of the Balkan Peninsula and of Russia. Its active economic life was to aid in the revival of trade and industry in the West. Meanwhile a vast offensive and creative movement developed in the southwestern quarter of Asia and across North Africa. A great new religion, Mohammedanism, arose, and it inspired the leadership of the Arabs in that amazing religious-political-economic imperialism which produced a new world power, and a new version of the old civilization. Islam. Successor to much of the Graeco-Roman heritage as well as to the Asiatic, Islam was instrumental in restoring the unity of the Mediterranean world; and by bringing Greek and their own learning into Spain and Sicily the Moslems were soon to be an important civilizing force in western Europe. In the Far East, Buddhism was again important in China, and during the 6th century it had spread into Japan, which was entering the realm of history. Under the T'ang dynasty the Chinese Empire and Chinese culture enjoyed a golden age of high achievement. Even in the West some creative activity was taking place: first from Ireland and then from Rome, Latin Christian missionary activities resulted in the conversion of the Germanic invaders of Britain, the organization of the English church, the foundation of new centers of learning, and the beginnings of Latin, Roman Christianity and culture in Holland and Germany.

Among all these movements the most important for the future of European civilization were undoubtedly the defense of the Byzantine Empire and the aggressive expansion of western Asia in the rise of Islam.

DEFENSE OF THE BYZANTINE EMPIRE

The ancient Roman Empire had been shattered in the West by the Germanic invasions and weakened in the East by the revived power of Persia under the Sassanids. The efforts of Emperor Justinian (r. 527–565) to regain what had been lost were rewarded with success in Italy, North Africa, and southern Spain. But the reconquest so devastated Italy that the Lombards were able to occupy the valley of the Po (Lombardy) and the Apennines, the empire retaining isolated territories, Venice, Ravenna, Rome, Naples, the southern tip of Italy, and Sicily. More unfortunate still was the consequence for the empire in the East, for the military effort in Italy had entailed the weakening of the eastern frontiers. The Slavs were pushing into the Balkans

and Greece, while an Asiatic horde, the Avars, who had settled in the plain of Hungary, repeatedly threatened Constantinople. Meanwhile Persia was generally on the offensive. Yet the able Emperor Maurice (r. 582–602) had checked the Persians and defeated the Avars and Slavs when a mutiny of his army on the Danube and an uprising in Constantinople ended his life and resulted in new disasters in the reign of his successor, the brutal Phocas (r. 602–610). Factional strife rent the great cities of the empire, and King Khosrau II Parvez of Persia occupied Roman Armenia, Mesopotamia, and Syria.

Victories of Emperor Heraclius.—Salvation came from Emperor Heraclius (r. 610–641), who obtained the throne when a rebellion started by his father against Phocas ended in success. But for several years longer the empire had to endure continued misfortune, renewed raids of Slavs and Avars, the capture by Khosrau of Jerusalem and the Holy Cross (reputedly the original cross on which Christ had suffered), and the Persian conquest of Egypt.

Then, aided by a great emotional response and crusading spirit in the name of the Mother of God, and by the loans (with interest) of the church and the leadership of Patriarch Sergius, Heraclius waged continuous war against the Persians while Sergius and the magister Bonus brilliantly and finally defeated the Avars in their attempt to capture Constantinople (626). Heraclius in 628 reached the heart of the realm of Khosrau, and recovered the Holy Cross, which was piously returned to Jerusalem, except for fragments given to the Armenians or brought back to Constantinople.

Once more the Byzantine Empire had survived, largely because of the genius of Heraclius. But the effort against Persia and the Avars had been exhausting, and Persia itself was disastrously weakened. The inevitable high taxes for the costs of war and loans to the church aroused dissatisfaction.

Religious Controversy and Reaffirmation.—More serious, perhaps, was the strong opposition to the orthodox empire and official church of the Monophysites (q.v.), who dominated Egypt and Syria. Since the 5th century the Monophysites, believing in the one, divine nature of Christ, had refused to accept the doctrine of the divine and human natures as defined by the Council of Chalcedon (451), for their monotheism was suspicious of anything that seemed to weaken the divine unity of the person of Christ. Patriarch Sergius and Heraclius in the edict *Ekthesis* (638) proposed as a compromise the doctrine of one divine will (monotheletism) in the two natures. Rejected by both sides, the doctrine of the Monotheletes (q.v.) in any case came too late to serve the purpose of regaining the loyalty of Egypt and Syria. Finally, in 680–681, when these provinces were irretrievably lost, the Council of Constantinople reaffirmed as orthodox the old doctrine of the two natures of Christ. But religious dissension had split and helped destroy the power of the empire in the Near East. These troubles explain why not even the ability of Heraclius, had his health remained, might again succeed in the defense of the empire against a new enemy, the Arabs.

RISE OF ISLAMIC CIVILIZATION

In the epic ebb and flow of the history of the relations between Europe and Asia the Persians had failed to end the long Graeco-Roman-Byzantine hegemony over Asia Minor, Syria, and Egypt that had begun with the conquests of Alexander the Great. Now, however, the internal weaknesses of the empire and the crippling of Persia opened the Fertile Crescent to a people who were ready to seize their opportunity—as they had done many centuries earlier. Inspired by a great religious leader, Mohammed (570–632), by their zeal to convert other peoples to the new universal faith, and by the lust for rich conquests, the Arabs became a great militant force and in the declining years of Heraclius embarked on their phenomenal career of religio-political imperialism.

Nature of Islam.—Mohammed, claiming divine inspiration, preached a religion founded on the belief in one God (Allah) and in Mohammed as his prophet. His teachings included an improved moral and social code for the Arabs (for example, forgiveness of enemies, sobriety, and a moderation of polygamy), as it included the reward of paradise for all Moslems (the faithful, or "self-surrenderers") who practiced the virtues commanded, offered prayers daily in the direction of Mecca, observed the annual fast of Ramadan, made the pilgrimage to Mecca, and fought for the faith. The new religion was called Islam ("surrender"), and Islam came to mean the ensemble of Moslems and their civilization. Mohammed's sayings were soon embodied in the suras (chapters) of the Koran (q.v.), the sacred book of Islam.

Expansion of Islam.—The success of the new religion was not immediate. But after the flight (hegira) in 622 from Mecca to Yathrib (Medina), Mohammed and his followers rapidly won numerous converts by defeating and plundering Meccan caravans and armies, gained control of Mecca in 628, and were unifying Arabia by the time of his death. Thereafter, within ten years, under able generals like Khalid and Amr ibn-al-As, the Arabs destroyed the army of Heraclius (Battle of the Yarmuk, 636) and occupied Syria, Palestine, and Egypt (Alexandria fell in 642); and they captured Ctesiphon and began the conquest of Asia eastward to the Oxus (Amu Darya) and Indus rivers. By the end of the 7th century, under the Umayyad caliphs of Damascus, the Arabs had completed the conquest of North Africa (Carthage finally fell to them in 698) from Libya to the Pillars of Hercules; and in a few years the converted Moors overthrew the Visigothic kingdom and occupied most of Spain.

Civilization of Islam.—From central Asia westward to the Atlantic, under the authority of the caliphs, the civilization of Islam came into being. If Arabic was the universal official and literary language, the learning of Islam came from the conquered peoples, and thus the new civilization incorporated the ancient Mediterranean learning (the Greek above all, with borrowings from India and China), and transmitted it to the West. Although it began as a reaction against Europe, and Moslem and Christian hostility often recurred, Islam carried on to new heights the unity of the old Mediterranean civilization; Mohammedanism itself was a part of the Semitic religious movements that had brought forth Judaism and Christianity, and in turn it too was influenced by Greek philosophy; there was no deep conflict between East and West, between Asia and Europe.

BYZANTINE AND ARABIC CULTURAL AND ECONOMIC LIFE

Despite the first overwhelming sweep of the Arabs, the Byzantine Empire was able to survive. Constans II (r. 641–668), defeated by the Arabs in the East, spent most of his time in Italy and Sicily. The opportune invention of Greek fire, however, gave the Byzantines control of the seas in time to beat off the Moslem fleet and save Constantinople (677). But with the Arabs remaining a threat to the capital and to Asia Minor, a new danger appeared in the settlement of the Hunnic Bulgars across the lower Danube. Yet the military strength of the empire, based on the reforms of Heraclius and the successful defense of the capital, resulted in the survival of Constantinople (once more in 717–718, when Leo III the Isaurian beat off the Arabs) as the mighty fortress defending Europe on the east, and as the center of Greek civilization from which Greek letters and Greek Christianity were to help in civilizing Russia, and an active economic life was to help in the later revival of western Europe.

Preservation of Ancient Learning.—In their different ways, therefore, Byzantines and Arabs during the 7th century preserved the ancient Mediterranean civilization and prepared the way for its development, when it entered the West, into medieval European civilization. Most of the creative work in this process would be done from the 9th to the 13th centuries. But Greek classical literature and learning at least survived and were studied in the Byzantine Empire, and Maximus the Confessor (580?–662) by popularizing the Pseudo-Dionysius' Neo-Platonic works on angelology helped increase the mystical element of Greek Christianity and, indirectly, of Jewish and Moslem thought. The invention of Greek fire (probably a mixture of quicklime, naphtha, pitch, and sulphur—with perhaps saltpeter, too) was a sign of continuing Greek technological genius. Already Greek philosophy, mathematics, and science had penetrated western Asia, and many of the works in these subjects were being translated into Syriac by Nestorian Christians in Syria, Mesopotamia, and Persia. The Syriac versions were later to be translated into Arabic.

Meanwhile, in the 7th century, Hindu mathematics reached a high level with the work of Brahmagupta (588–?660). The so-called Hindu numerals were even now appearing in Mesopotamia, where Severus Sebokht (fl. 650) was acquainted with them. This scholar was also a student of Aristotelian philosophy. Thanks in part to him, Islam was destined to absorb, build on, and transmit Greek and Hindu knowledge.

Economic Life.—Like the cultural life of the century in the Near East, the ancient economic life continued to exist, if it did not always flourish because of war and raids. But the Arabs and their subjects in Syria and Egypt and North Africa soon expanded trade between Asia and the Byzantine Empire and Spain. At times there was some interruption of the old commerce between the eastern Mediterranean and western Christendom, but internal troubles were a more important factor in the continuing economic decline in Italy and in Gaul. In fact, along with the Byzantines, the Arabs renewed the economic unity and prosperity of the Mediterranean world and in a few centuries stimulated the revival of trade and industry in the Latin West.

WESTERN DISUNITY

Localism in Western Europe.—No such continuity of the ancient world was apparent in the western half of the Roman Empire. Italy in the 7th century was itself divided between the loosely knit Lombard kingdom and the scattered territories of the Byzantine Empire. A renewal of Greek culture in Sicily and the extreme south came with the settlement of many refugees from Greece and the East. The Lombard kings were not strong enough to conquer the whole peninsula, papal Rome in particular being a serious obstacle. The hardening of this localism in the 7th century explains why no power could make Italy more than a geographical expression until the 19th century.

As for the Roman Church, the achievements of Pope Gregory I the Great in the preceding period resulted in the survival of the papal control of the territory that was the nucleus of the later Patrimony of Peter or Papal States. The popes held firm in doctrinal disputes with the patriarchs of Constantinople and the emperors, and their staunch adherence to the doctrine of the two natures of Christ won a definitive victory at the Council of Constantinople in 680–681. They did not, however, secure recognition as superior to the patriarchs of Constantinople, and ultimately the great schism of the Eastern and Western churches resulted.

The kingdom of the Franks in Gaul and the valley of the Rhine was in danger of falling to pieces as the Merovingian dynasty was weakened by the power of the nobles and the loss of crown lands and revenues. Dagobert I (r. 628–638) enjoyed great prestige but was the last of the line to rule more than nominally over the realm as a whole. The chief administrative officer of each division of the kingdom, the mayor of the palace, was becoming the actual ruler. One of these mayors, Pepin of Herstal, in his victory at Tertry (687) won virtual control of the whole kingdom. His son, Charles Martel, in 732 repelled the Moors of Spain and was the founder of the great Carolingian dynasty.

In Spain the Visigothic kings were trying to establish a real public authority and a strong state. Indeed, the memory of the unity of Spain under these kings contributed to the rise of the tradition of an independent Spanish empire, and a feeling of Spanish nationalism, during the reconquest from the Moors. Yet the monarchy was dominated by the clergy; and the dissatisfaction of great nobles and the unhappiness of the persecuted Jews soon made Visigothic Spain an easy prey for an invading Moslem force (711).

Roman Britain had disappeared. The native British were pushed into the extreme west or across the channel into Armorica (hence Brittany), and the several kingdoms of the Germanic Angles, Saxons, and Jutes showed as yet no promise of the unity that later became England.

Forces of Unity.—Altogether, then, in western Europe the localism introduced by the Germanic invaders became permanent and defeated medieval efforts to revive the Roman ideal of political unity; the final outcome was nationalism. Yet some of the common Roman heritage in institutions and law was vaguely reappearing in these barbarian kingdoms. Frankish, Lombard, and Visigothic kings tried to rule with the old authority that Roman emperors had enjoyed, and to revive the idea of a public law and state superior to tribal distinctions and private rights.

The *Edictus* (643) of the Lombard king Rothari (r. 636–652) asserted the royal power and codified the law. King Receswinth (r. 649–672) in Spain issued a codification of the Roman and Visigothic laws (the *Liber Judiciorum,* 654), thus replacing the Germanic personality of the law with the Roman ideal of a body of law common to all within the state.

But the Roman heritage survived and spread above all through the missionary strength of Latin Christianity. Latin, and even Greek, learning and literature had been flourishing in Irish monasteries, and by 615 Irish monks had carried their Christianity and Latin letters into Scotland, Northumbria, Bavaria, Gaul, and northern Italy; St. Columban (543–615) founded the monastery of Bobbio (c.612), where the monks began the study of books that came from the old library of Cassiodorus. The bishops of Rome, however, now became the chief leaders of the movement. In 597, Gregory the Great began the papal policy of sending Benedictine monks from Rome to convert the Angles and Saxons to Roman Christianity. Gradually Benedictine monasticism superseded the Irish, and at the Synod of Whitby (664) the Irish accepted Roman practices (the dating of Easter and the tonsure of priests) and the authority of the popes. The unity of the Roman Church was firmly established. In 668, Pope Vitalian (r. 657–672) appointed a learned Greek scholar, Theodore of Tarsus, archbishop of Canterbury, who began the organization of the English church. At the same time the African abbot Hadrian made Canterbury an important center of Latin learning, and Benedict Biscop founded the famous schools of Jarrow and Wearmouth. By the end of the 7th century, finally, Anglo-Saxon monks were the successors of the Irish in missionary work on the Continent. Aided by Pepin of Herstal and Charles Martel, who wished to extend the power of the Franks, Willibrord and Winfrid (St. Boniface) began the conversion of Frisia (Holland) and Germany. The monasteries and churches founded by them and their disciples hastened the rise of an active agricultural life as well as learning, and the entrance of Germany into the world of Roman civilization.

Western Intellectual and Artistic Life.—The religious and cultural unity of western Europe was now at hand, but as yet creative efforts in literature, learning, and the arts were poor and unoriginal. Archbishop Isidore of Seville (560?–636), however, compiled an encyclopedia (the *Etymologies*) which reveals an extensive knowledge, still possible in Spain, of all fields of the learning that had survived about the world and man, about Christian doctrine, the Latin language and grammar, medicine, law, the natural sciences, and technology. The encyclopedia is elementary, but it became the standard work of reference in medieval education. In Ireland and Anglo-Saxon England the Latin poetry of monks like Aldhelm (640?–709), though not great literature, reflected a competent knowledge of the classics. An anonymous treatise, *On the Twelve Abuses of the Age,* offers an intelligent discussion of the duty of the king to protect the weak, rule according to law and justice, and maintain the common welfare. Anglo-Saxon literature began with Caedmon's *Hymn of Creation,* based on the Biblical story, and, possibly, with the first Germanic epic, *Beowulf* (q.v.), although some scholars place the latter as late as the 10th century. Meanwhile, the schools of Wearmouth and Jarrow were educating Bede (673–735), whose mature Latin scholarship leads into the 8th century and the Carolingian renaissance.

Rome had stopped at the Rhine and the Danube. Barbarian kingdoms, even trade and piracy, and above all Irish, Roman, and Anglo-Saxon missionaries extended the universalism of Rome to northern Europe and thus limited the extreme particularism of politics, languages, and customs. Indeed, by the end of the 7th century, Latin Christianity and civilization were the one unifying force in all western Europe. Stemming from Rome in western Europe, from Constantinople in eastern Europe, from both and from Islam in Europe as a whole, the ancient Mediterranean civilization was about to become European.

GAINES POST,
Professor of History, University of Wisconsin.

PRINCIPAL EVENTS OF THE 7TH CENTURY

604—Death of Pope Gregory I the Great.

618—Beginning of the T'ang dynasty in China and a brilliant period of Chinese culture.

622—The flight (hegira) of Mohammed from Mecca to Yathrib (Medina).

628—Emperor Heraclius victorious over Sassanid Persia.

628–638—Dagobert, last important Merovingian king of the Franks.

636—Death of Archbishop Isidore of Seville; decisive defeat of the Byzantine army by the Arabs in the Battle of the Yarmuk, and Arab conquest of Syria follows.

641—The Arabs complete the conquest of the Persians.

642—The Arabs take Alexandria and complete the conquest of Egypt.

643—*Edictus* (Lombard code of law) of Rothari.

654—The *Liber Judiciorum,* code of Roman-Visigothic law for Spain.

664—Council of Whitby; unity of Irish and Roman Christianity under the papacy assured.

669—Theodore of Tarsus, archbishop of Canterbury, arrives in Britain and begins to organize the English church under the authority of the Roman Church.

677—Greek fire and Byzantine seapower assure successful defense of Constantinople and the empire against the Arabs.

680–681—Sixth ecumenical council at Constantinople and final triumph of doctrine of the two natures of Christ.

687—Battle of Tertry; Pepin of Herstal as mayor of the palace acquires control of the Merovingian kingdom of the Franks.

698—The Arabs capture and destroy Carthage, completing conquest of North Africa.

SEVENTH-DAY ADVENTISTS, an evangelical denomination having its origin in 1844, when a New Hampshire congregation, connected with the Advent Movement, began observing the seventh day as the Sabbath. They believe in the imminent premillennial return of Christ; that immortality is a gift through Christ; that the living righteous will be translated and the righteous dead resurrected at the Advent; and that all the wicked will ultimately be destroyed. They emphasize Bible prophecy, and believe in the gift of prophecy. Their tithes and offering for 1952 totaled $52,240,980, and their foreign mission budget for 1953 was $18,562,822. They conduct 269 colleges and secondary schools, 43 publishing houses, issuing nearly $14,000,000 worth of literature in 197 languages, and operate 108 sanitariums and hospitals and 57 dispensaries. Their headquarters is in Washington, D.C. At the close of 1951 their churches numbered 10,585, with a membership of 803,720.

SEVENTH DAY BAPTISTS. See BAPTISTS.

SEVERINUS, sĕv-ĕr-ē′nŭs, **Saint,** the Apostle of Norica: b. either in northern Africa or southern Italy; d. Jan. 482. After the death of Attila in the 5th century he journeyed through the territory along the Danube, preaching Christianity, and through his courage and good work gained great influence over the people and made many converts.

SEVERN, sĕv′ĕrn, **Joseph,** English artist: b. Hoxton, Dec. 7, 1793; d. Rome, Italy, Aug. 3, 1879. He was self-taught and won, after great struggles, the Royal Academy historical painting prize in 1818. Early in life he formed a friendship with the poet Keats, for which he is chiefly noted; in 1820 accompanying the poet to Italy, and caring for him there until Keats' death the following year. He painted several portraits of Keats. In 1821 Severn exhibited *The Death of Alcibiades* at the Royal Academy and won a traveling pension. He subsequently served as British and as Italian consul at Rome, where he lived until his death, devoting his time chiefly to the painting of miniatures.

SEVERN, England, the second river in size and most important in the country, rises at Maes Hafren in Montgomery County, and after a winding course of about 200 miles falls into the Bristol Channel. The Vyrnwy enters the Severn on the Shropshire borders, the Wye, below Chepstow and the Lower Avon about eight miles below Bristol. At Welshpool the Severn begins to be navigable, about 178 miles above its mouth.

SEVERO, sā-vā′rō, or **NORTHEAST CAPE.** See CHELYUSKIN, CAPE.

SEVERUS, sę-vē′rŭs, **Alexander.** See ALEXANDER SEVERUS.

SEVERUS, Lucius Septimius, Roman emperor: b. near Leptis Magna, Africa, 146 A.D.; d. York, Britain, 211 A.D. After the murder of Pertinax, in March 193 he was proclaimed emperor by his troops at Carnuntum. Thereupon he marched to Rome to crush the partisans of Didius Julianus, who had meanwhile purchased the imperial purple from the Praetorians. On his approach Julian was deserted and assassinated by his own soldiers. In professing that he had assumed the purple only to revenge the death of the virtuous Pertinax, Severus gained many adherents and was enabled to banish the Praetorians. But while he was victorious at Rome, Pescennius Niger was in the East at the head of a powerful army, by which he also had been called to the purple. Getting rid of the rivalry of Albinus by conferring upon him the title of Caesar, Severus at once directed his arms against this eastern competitor. On the plains of Issus, Niger was totally ruined by the loss of 20,000 men (194). After devastating some territory beyond the Euphrates. Severus took Byzantium, which had shut her gates against him, but only after a protracted siege (196); and he then returned to Rome, resolved to destroy Albinus. He attempted to assassinate him by his emissaries, but when this failed, Severus had recourse to arms, and defeated Albinus near Lyons (197). After returning to Rome Severus marched into the East to repel an invasion of the Parthians. From Parthia he marched toward the more southern provinces of Asia and entered Alexandria. A rebellion in northern Britain called him away again in 208. After penetrating to the far north of Caledonia, and losing a vast number of men, he returned southward and rebuilt or repaired the wall of Hadrian across the island from the Tyne to the Solway Firth.

Consult Platnauer, M., *The Life and Reign of the Emperor Lucius Septimius Severus* (Oxford 1918).

SEVERUS, Wall of. See HADRIAN'S WALL.

SEVIER, sĕ-vēr′, **John,** American pioneer: b. Rockingham County, Va., Sept. 23, 1745; d. near Fort Decatur, Ga., Sept. 24, 1815. Having founded the town of Newmarket, Shenandoah County, Va., and there become a celebrated Indian fighter, he served as captain in the Virginia line during Lord Dunmore's War (1774; see COLONIAL WARS IN AMERICA). He had removed in 1772 to the Watauga colony on the western slope of the Alleghanies and been, next to John Robertson (q.v.), the most prominent of the settlers. Now, at the beginning of the Revolution, he drafted a memorial to the legislature of North Carolina, requesting annexation to that colony, and as a result all of the present Tennessee was made a county of North Carolina and known as Washington district. He served in the North Carolina legislature and was appointed district judge at Watauga. Elected colonel of the trans-Alleghany forces, he commanded in many Indian fights, distinguishing himself at Boyd's Creek (1779) and King's Mountain (1780). After the war, North Carolina found that the retention of the large section now known as Tennessee would entail obligations for a corresponding portion of the Federal debt and, therefore, the tract was made over to the central government. The settlers then determined to organize an independent State and regularly apply for admission to the Union. At a convention held Aug. 23, 1784, Sevier was elected governor of the new State of Franklin, as it was called. North Carolina now recognized its mistake and granted Watauga a Superior Court, besides organizing the militia troops into a brigade with Sevier as brigadier. But Sevier entered office as governor March 1, 1785, reorganized the military, established a Superior Court and con-

cluded treaties with the Cherokees. In 1787 North Carolina declared the Franklin government a revolt, subdued it by force of arms, imprisoned Sevier, and ceded the region to the federal government. In 1796 Sevier was elected first governor of the new state of Tennessee. He served six terms (1796–1801 and 1803–1809). He was elected to Congress in 1811 and died while in office.

Consult Driver, Carl, *John Sevier* (Chapel Hill, N.C., 1932).

SEVIER LAKE, sĕ-vēr′, lake, Millard County, west-central Utah, altitude 4,600 feet. At one time second in size only to Great Salt Lake among the residual salt lakes left by the Pleistocene Lake Bonneville, it has been greatly reduced by large-scale diversion for irrigation of its only major affluent, the Sevier River, which enters it from the north. At its highest modern stage, in 1872–1873, Lake Sevier was 28 miles long and 10 miles wide, with an area of 188 square miles. Now it has more the character of an enormous salt marsh. In dry years much of its bed is incrusted with salt deposits, principally sodium chloride, sodium sulphate, and magnesium sulphate. The lake has no present outlet, but at an earlier stage in the recession of Lake Bonneville it drained north into Great Salt Lake; the old river bed is still discernible.

The Franciscan fathers, Silvestre Vélez de Escalante and Francisco Atanasio Dominguez, were told of the lake by the Indians during their exploration of 1776. It was early known as Lake Miera or Lake Buenaventura; under the latter name it became confused in cartography and legend with Great Salt Lake. Its present name derives from the Spanish Severo, corrupted by American trappers to Sevier. The first recorded visit to the lake by white explorers was by a party of fur hunters which included the American trapper Daniel T. Potts, early in 1827.

SEVIGNE, sā-vēn-yā′, Marquise de (Marie de Rabutin-Chantal), French literary figure: b. Paris, France, Feb. 5, 1626; d. Grignan, Drôme, April 17, 1696. She was the daughter of the Baron de Chantal, was left an orphan at the age of six, and was reared chiefly under the guidance of her uncle, the Abbé of Livry. She was married in 1644 to the Marquis Henri de Sévigné, who was killed in a duel in 1651, leaving her the mother of a son and a daughter. Her wealth, beauty, talent, and social position brought her offers of marriage, but she devoted herself, rather, to her children, to reading, and to the brilliant social and literary circle of the Hôtel Rambouillet in Paris. She was deeply attached to her daughter, who in 1669 married the Comte François de Grignan and shortly afterward accompanied him to Provençe, where he had been appointed lieutenant governor. This separation resulted in the voluminous correspondence which, while not intended for publication, has been given to the world and has made Mme. de Sévigné famous as a personality, as a literary stylist, and as a recorder of the social life of the resplendent court of Louis XIV.

The bulk of Mme. de Sévigné's 1,700 letters cover the seven year period following her separation from her daughter. (Later in life they were rarely apart.) The correspondence abounds in delightful gossip, witty anecdote, clever remarks on men and topics of the day, and graceful delineations of the pleasures and the gaieties of Parisian society. They mirror the life of the woman who was in turn the noted court beauty, the brilliant wit of the Hôtel Rambouillet, the religious devotee, the woman of business endeavoring to meet the demands placed on her income by her extravagant son, the appreciative student of the Latin and French classics, and always the devoted mother, deploring the separation from her daughter.

The letters were published first in 1726. Definitive is Louis J. N. Monmerqué's revised edition (14 vols., Paris 1862–68), supplemented by the *Lettres inédites,* prepared by Charles Capmas (2 vols., Paris 1876). The first volume of a new French edition, edited by Émile Gerard-Gailly, appeared at Paris in 1953. Standard French biographies are by Paul Mesnard (in the Monmerqué edition of the letters) and Baron Charles A. Walckenaer (5 vols., Paris 1842–52), and other editions). A modern English edition of the letters is by Alfred E. Newton (7 vols., Philadelphia 1928). Recent selections in English, with biographical commentary, have been prepared by Richard Aldington (2 vols., London 1937), Arthur S. Megaw (London 1946), and Violet Hammersley (New York 1956), the latter containing a preface by W. Somerset Maugham.

SEVILLE, sĕ-vĭl′ or sĕv′l (Span. Sevilla, sā-vēl′yä), southwest Spain: (1) inland seaport, capital of Seville Province, fourth city of Spain in population, situated on the east bank of the navigable Guadalquivir River, 50 miles from the Atlantic and 60 miles north-northeast of Cadiz. Seville is an important industrial and commercial city as well as seaport, but it is even more famous for its great historic and artistic monuments and traditions. The principal buildings of the city are grouped around or near the Plaza del Triunfo. The enormous Gothic cathedral (built 1402–1519) contains a profusion of works of art and historical treasures. There are paintings by Murillo, El Greco, and other famous artists. The cathedral is the second largest Christian church in the world, being surpassed only by St. Peter's in Rome. Architecturally notable are the adjacent Giralda (q.v.), or Bell Tower, and the delicate Moorish stone tracery which decorates the interior of the church. North of the cathedral is the Patio de los Naranjos, with the library of Columbus and a Moorish fountain. The Alcazar, however, is the chief specimen of Moorish architecture in Seville. It is considered second only to the Alhambra of Granada in beauty and historic interest. Construction of this fortified palace was begun in 1181. Conspicuous features are the ornate façade, the hall of the ambassadors, and the Patio de las Muñecas. In the rear are beautiful gardens. The Lonja, or exchange, is the repository of many important historical documents. The Ayuntamiento, or city hall, is a fine specimen of Renaissance architecture. It is situated between the Plaza de la Constitucion and the Plaza de San Fernando. Adjoining the city hall is the Audiencia, or court of justice. Other noteworthy buildings include the old tobacco factory, which inspired the first-act stage setting of Bizet's *Carmen;* the Casa de Pilatos, dating from the 15th century, with a fine colonnade and courtyard; and the Casa de las Dueños, with its numerous courtyards and nine fountains. There are many old and beautiful churches, including Omnium Sanctorum, San Marco, Santa Maria

la Blanca (an ancient synagogue), and La Caribad (the latter containing several *chef d'œuvres* by Murillo and J. de Valdes Leal. Many of the churches, in themselves uninteresting, contain masterpieces of sculpture and painting. The Museum contains works of art of inestimable value, representing the School of Seville (16th and 17th centuries). Other notable buildings include the University (1254) (1567), formerly a convent; the archbishop's palace; the royal cigar factory, "Fabrica de Tabacos," an enormous and palatial building, with many courts, fountains, and tropical plants; the palace of San Telmo and the picture gallery. The chief squares not mentioned are the Plaza Nueva, the Plaza del Duque, the large bull-ring, which ranks next to that at Madrid, and the Quemadero, the former scene of the *Autos-da-fé*. Las Delicias is a charming promenade along the river bank. The suburb of Triana is inhabited by gypsies and the poorer class. The Guadalquivir is a tidal river and navigable for large vessels into the city itself. Seville has always been an important commercial port. The exports include lead, quicksilver, iron ore, olives, oranges, cork and copper pyrites; the imports timber, drugs, chemicals, coal, coke, machinery, petroleum and coffee. The principal manufactures are tobacco, porcelain, hardware, soap, leather goods, chocolate, corks, etc. The Pickman tile factory at Cartuja is an old and noted porcelain manufactory. A railway connects the city with Cadiz and Cordova, and an iron bridge and two other bridges (one belonging to the railway) connect it with Triana (where typical peasant games and costumes are seen). Seville was first colonized by the Phœnicians, from whom it passed in turn to Romans, Vandals, Visigoths and Arabs and was finally taken by Ferdinand of Castile (1248), 300,000 Moors voluntarily seeking exile. It suffered many revolutions prior to this period, and later was depopulated by a yellow fever scourge. Under Soult (1810) the French robbed the city of her riches. The discovery of America gave the town considerable commercial importance as the seat of American trade. It is the birthplace of Velasquez Murillo and other celebrities. Pop. about 238,727. Consult Calvert, A. F., 'Seville' (London 1907); Gallichan, W. M., 'The Story of Seville' (London 1903).

(2) The province has an area of 5,428 square miles, and forms a part of Andalusia. The summits of the Sierra Morina rise at the north to a high elevation; south, the surface is low and fertile. The Guadalquivir is the principal river, and its affluents are the Genil, the Guadira, and the Guadalimar. The province is exceedingly fertile and produces all cereals and vegetables. The exports include tobacco, leather, paper, chocolate, silk and woolen goods, glass, soap and pottery. The chief European domestic animals are abundant, and in the higher districts occur copper, silver, lead, iron, coal, and salt mines, besides chalk and marble. Trade has developed rapidly by the building of railways in recent times. Four senators and twelve deputies represent the province in the Cortes. The chief towns are Seville (q.v.), Carmona, Constantina, Ecija, Lebrija, Marchena, Morón de la Frontera, Osuna and Utrera. Pop. about 849,841.

SEVRES, sāvr, France, in the departmenr of Seine-et-Oise, on the Seine, lies about 10 miles southwest of Paris, and an equal distance from Versailles. Its celebrated porcelain manufactory, founded at Vincennes in 1745 and removed to Sevres in 1756, was purchased by Louis XV, 1760. In 1876 the old and dilapidated buildings were replaced by a new structure, erected in the park of Saint Cloud. The Porcelain Museum contains numerous articles of china collected from all over the world, which represent every age and clime. A technical School of Mosaics was established here in 1875. Besides the celebrated Sèvres vases, painted glass and mosaics are made. In the artistic pottery the *pâte-sur-pâte* (or layers) method is used — original to this manufactory. The general effect is that of a cameo, though possessing greater delicacy and rich coloring. (See Ceramics; Porcelain). Sèvres has other manufactures of shawls, cordage, leather and chemicals. It was occupied by the German troops in 1870, bombarded by the French a few weeks later, and attacked by the troops of the Commune in 1871. Pop. about 8,500.

SÈVRES, Deux, a western department of France. In the northern, central and western portions the country is marshy. although it has been well drained in parts. In the southern part it is a limestone plateau. The chief rivers are the Sevre-Niortaise in the south, and the Sevre-Nantaise, which joins the Loire near Nantes. The northern part is known as the Gatine. The capital is Niort. In the south and southeastern parts of the department grain, beets and forage are grown, while hemp is produced in the west. There is some production of wine. On account of the extent of marshlands, wild fowl are abundant. Horses and mules are bred. The chief manufactures are cloth and woolens. The department has an area of 2,337 square miles, and a population of 308,841.

SEVRES PORCELAIN. See Porcelain.

SEVRES, Treaty of. See Turkey.

SEWAGE. See Sanitary Engineering; Wastes, City, Disposal of; Garbage.

SEWALL, Jonathan Mitchell, American poet: b. Salem, Mass., 1748; d. Portsmouth, N. H., 29 March 1808. He studied at Harvard, was for a time in trade, but took up the law, practised in Grafton County, N. H., and became register of probate there in 1774. His songs and verses appeared widely in American newspapers in the Revolutionary time, 'War and Washington' being among those familiar to the army. Probably a good share of his poetry was, like 'On Independence,' of the "pompous, rhetorical, and truly ligneous variety." But he wrote for a performance of Addison's 'Cato' at Portsmouth (1788), an epilogue, the concluding two lines of which are frequently quoted:

> "No pent-up Utica contracts your powers;
> But the whole boundless continent is yours!"

Sewall was a Federalist, and a "wit" of the time. A volume of his 'Poems' containing paraphrases of Ossian and of Washington's 'Farewell Address' appeared in 1801.

SEWALL, Mary Wright, American educacator: b. Milwaukee, Wis., 27 May 1844; d.

22 July 1920. Graduated from the Northwestern University, Watertown, Wis., in 1866, and was married to Theodore Lovett Sewall (d. 1895) in 1880. She became prominently connected with various woman suffrage associations, lectured extensively on woman suffrage, and served as delegate to numerous congresses in connection with that movement. She was identified as a manager of the Columbian Exposition at Chicago in 1893; was appointed by President McKinley commissioner to the Paris Exposition and its congresses in 1900; and was associated in 1915 with the Panama-Pacific Exposition. She was principal of the Girls' Classical School founded in Indianapolis by her husband until she retired into private life. She published various articles on literary and reform subjects, besides 'Historical Résumé of the World's Congress of Representative Women,' and 'Women, World War, and Permanent Peace' (1916).

SEWALL, Samuel, American jurist: b Bishopstoke, Hampshire, England, 28 March 1652; d. Boston, Mass., 1 Jan. 1730. He was graduated from Harvard in 1671, was ordained to the ministry, but was "diverted into a prosperous and benign secular career," started a printing-press at Boston, and entered public life as a member of the board of assistants. In 1692 he was made a member of the council and judge of the Probate Court, and in the latter capacity joined in the sentence of condemnation against witches at the time of the historic delusion. When he had realized his error he made in 1697 a public confession in church, and afterward spent therefor one day annually in fasting and prayer. He was appointed judge of the Supreme Court of Massachusetts, and from 1718 until his retirement in 1728 was its chief justice. He was possibly the first in America to attack negro slavery, publishing on the subject 'The Selling of Joseph' (1700), a three-page tract of much eloquence. But he is best known for his diary, a garrulous detail of every sort of minutiæ, comparable in this sort to Pepys or Evelyn, and extending from 1674 to 1729. It naturally affords a most valuable source for the political and social history of the colony. In fact, "we have (Chamberlain) no other book like it." Tyler calls Sewall "great by almost every measure of greatness." The diary was printed in volume V of the fifth series of the 'Collections' of the Massachusetts Historical Society.

SEWARD, sū'ard, **Anna,** English poet: b. Eyam, Derbyshire, 1747; d. Lichfield, 25 March 1809. She was a daughter of Thomas Seward, canon of Lichfield, and was known as "the swan of Lichfield." Some of her earlier poetical efforts were an 'Elegy on the Death of Mr. Garrick' and an 'Ode on Ignorance.' Her literary aspirations were fostered by her fellow-townsman, Dr. Erasmus Darwin, of whom she later wrote a 'Memoir' (1804). Her greater success was achieved with a 'Monody on the Death of the Unfortunate Major André' (1781), and an elegiac poem on 'Captain Cook' (1807). Horace Walpole declared she had "no imagination, no novelty," and Miss Mitford spoke of her as "all tinkling and tinsel — a sort of Dr. Darwin in petticoats." Her poems were published in 1810 with a memoir by Sir Walter Scott.

SEWARD, Clarence Armstrong, American lawyer and politician, nephew of W. H. Seward (q.v.): b. New York, 7 Oct. 1828; d. Geneva, N. Y., 24 July 1897. He was graduated at Hobart College in 1848, studied law and practised in New York after 1854. He was judge-advocate-general of New York State in 1856–60; and served as Acting Assistant Secretary of State of the United States after the attempted assassination of Secretary of State Seward in 1865. He was active in the creation of the State of West Virginia; and assisted Judge Blatchford in preparing 'New York Civil and Criminal Justice' (1850).

SEWARD, Frederick William, American lawyer, son of W. H. Seward (q.v.): b. Auburn, N. Y., 8 July 1830; d. 1915. He was graduated from Union College in 1849, admitted to the bar in 1851 and for 10 years was one of the editors and owners of the Albany *Evening Journal.* In 1861 he was sent to apprize Lincoln of the plot to assassinate him in Baltimore, served as Assistant Secretary of State in 1861–69 and in 1877–81, and narrowly escaped death in defending his father from an assault, 14 April 1865. He went with Admiral Porter on the special mission to negotiate the treaties with West Indies in 1867, assisted in the purchase of Alaska, and in the negotiations for Pago-Pago Harbor, Samoa. He was a member of the New York legislature in 1875, State commissioner at the Yorktown Centennial Celebration in 1881 and in 1900 became president of the Sagaponack Realty Company. He published 'Life and Letters of William H. Seward' (1891); 'A West Indian Cruise' (1894), and numerous articles in reviews and magazines.

SEWARD, George Frederick, American diplomat, nephew of W. H. Seward (q.v.): b. Florida, N. Y., 8 Nov. 1840; d. 1910. He was educated at Union College, and in 1861 was appointed United States consul to Shanghai, China, where he remained until 1876, serving as consul-general from 1863. In 1876–80 he was Minister to China, but was recalled in the last-named year in consequence of refusing to undertake the negotiation of a treaty to restrict Chinese immigration. During his residence in China he was active in suppressing riots and in reducing piracy. He was vice-president of the North China branch of the Royal Asiatic Society after 1887, and after 1893 was president of the New York Fidelity and Casualty Company. He published 'Chinese Immigration in Its Social and Economic Aspects' (1881); 'Digest of System of Taxation of New York' (1902), etc.

SEWARD, William Henry, American statesman: b. Florida, Orange County, N. Y., 16 May 1801; d. Auburn, Cayuga County, N. Y., 10 Oct. 1872. He was graduated from Union College (1820), and having studied for the law, began practising at Auburn in 1823, but soon indicated a decided bent for politics, which gradually drew him away from the legal profession. In 1830 he was elected as an anti-Masonic candidate to a seat in the New York senate, and from that date he was, with few intervals, in one form or another, an effective and prominent leader in the councils that framed the policy

both in his own state and of the nation. In 1838 he was elected first Whig governor of New York by a majority of 10,421. Though his administration was rendered peculiarly difficult by the internal dissensions of his party, it was marked by wise measures of reform, which definitely added to Whig strength in the state. During his term many of the disabilities of foreigners were removed, the antirent troubles were adjusted, the natural history and geological survey of the state was commenced, the state museum of natural history was established and a bill was passed securing for fugitive slaves a trial by jury with counsel furnished by the state. He was re-elected in 1840. From 1843 to 1849 he was occupied largely with professional practice, though he delivered several addresses on political and other topics.

He was elected in 1849 to the Senate, and there attained great influence as both a party leader and an adviser of President Taylor. In a speech of March 11, 1850 in favor of the admission of California, he spoke of the exclusion of slavery from all new states as demanded by "the higher law," a phrase which greatly offended Southern Democrats, and was made one of the battle cries of Abolition. Upon Fillmore's accession, Seward strongly opposed that president's proslavery attitude, though this was accepted by many Whigs in Congress. Having been re-elected senator in 1855, he took a leading part in the discussion, immediately antecedent to the rebellion.

In an address at Rochester, N. Y., in October 1858, he made reference to the "irrepressible conflict" whose outcome must make the United States a nation either all of free labor or all of slave. In 1856 and again in 1860 he was the most prominent Republican candidate for the presidential nomination, receiving on the first ballot at the Chicago convention in 1860, 173½ votes as against 102 for Lincoln, who was eventually chosen. Seward, however, spoke for Lincoln in the West and East, and was made secretary of state. This post he filled with notable efficiency, particularly in connection with the foreign relations of the government. He reorganized the diplomatic service, and by his able dispatches and the instructions furnished to representatives abroad retained the confidence of Europe, which had been ready to grant recognition and support to the Confederacy.

A famous incident of his secretaryship was the correspondence with Great Britain apropos of the "Trent affair." When the Confederate agents, Slidell and Mason, were removed from the British ship *Trent,* their restoration was peremptorily called for and war seemed certain. The answer, formulated by Seward and slightly amended by Lincoln, by its skill, closed the matter. Great Britain, it said, now recognized the principle of exemption from search, contended for in the War of 1812 by the United States, which now, therefore, willingly released the prisoners. Seward insisted on redress for American citizens for depredations by the *Alabama* (see ALABAMA CLAIMS). Secretary Seward firmly asserted the Monroe Doctrine in relation to the French invasion of Mexico, but, by avoiding a provocative attitude, which might have involved his government in a foreign war, was able to defer the decision to a more favorable time. Before the close of the Civil War he intimated to the French government the irritation felt in the United States in regard to its armed intervention in Mexico. Many dispatches on this subject were sent during 1865 and 1866, which gradually became more urgent, until the French forces were withdrawn and the Mexican Empire fell. Seward supported Lincoln's proclamation liberating the slaves in all localities in rebellion, and three years later announced by proclamation the abolition of slavery throughout the Union by constitutional amendment.

In the spring of 1865 Seward was thrown from his carriage, and his arm and jaw were fractured. While he was confined to his couch with these injuries President Lincoln was murdered, and on the same evening, April 14, one of the conspirators gained access to the chamber of the secretary, inflicted severe wounds with a knife in his face and neck, and struck down his son, Frederick W., who came to his rescue.

He negotiated treaties for the purchase of the Danish West India Islands and the Bay of Samoa, which failed of approval by the Senate, and made a treaty with Colombia to secure American control of the Isthmus of Panama, which had a similar fate. Seward sustained the reconstruction policy of President Johnson, and thereby alienated the more powerful section of the Republican Party and subjected himself to bitter censure and ungenerous imputations. He opposed the impeachment of the president in 1868, and supported General Grant for the presidency in the same year. Meanwhile, in 1867, he had negotiated the purchase of Alaska from Russia. After his retirement (March 1869), he visited "Seward's Folly," as his critics called Alaska, and in 1870 made a tour of the world.

Seward, from 1801 to 1834, with a Memoir of His Life,* and *Selections from His Letters, from 1831 to 1846* and *Seward at Washington,* 2 vols. (1891); Baker, G. E. (ed.), *The Works of William H. Seward,* 5 vols. (1884); Hale, E. H., *William H. Seward* (1910); Hendrick, B. J., *Lincoln's War Cabinet* (1946).

SEWARD, sū'ĕrd, city, Alaska, on Resurrection Bay. It is the southern and seaward terminus of the Alaska Railroad, and terminus of the Anchorage-Seward Highway. It is the chief community of the Kenai (keen eye) Peninsula which is noted for its big game hunting (moose, bear, and mountain sheep) and sport fishing. Industry centers around the railroad and waterfront. The city's deep-water harbor is visited by most steamers entering the territory. It has a territorial tubercular sanitarium, and a native school. Pop. (1950) 2,063; the district, 2,653.

SEWARD, city, Nebraska, and Seward County seat, altitude 1,442 feet, on the Big Blue River, 25 miles by highway northwest of Lincoln. It is served by the Burlington Route and North Western Lines and by federal and state highways. It is a trading center for the surrounding agricultural region. Located here is one of the large manufacturers of electric power line materials but most of its other industries are connected with agricultural pursuits.

It is the seat of Concordia Teachers College. The city was named for Lincoln's secretary of state and platted in 1868. It has a mayor and council government. Pop. (1950) 3,154.

SEWELL, Jonathan, Canadian jurist: b. Cambridge, Mass., 1766; d. 1839. He was edu-

cated at Bristol, England, and in 1785 he settled in Canada. He studied law, was called to the bar in 1789 and engaged in practice at Quebec. He was appointed solicitor general in 1793, and in 1795 became attorney general and judge of the Court of Vice-Admiralty. In 1808–1838 he was chief justice of Lower Canada. He made the decision concerning the disputed boundaries of Ontario, in 1818. He was president of the executive council in 1808–1829; and from 1809 he was speaker of the legislative council. He is said to have made the original proposal for the Canadian federation while in England in 1814. Author of *Plan for the General Federal Union of the British Provinces in North America* (1815); *Essay on the Judicial History of French Law so Far as it Relates to the Law of the Province of Lower Canada* (1824).

SEWELL, sū'ĕl, **Robert van Vorst,** American artist: b. New York, 1860; d. Florence, Italy, Nov. 18, 1924. He was graduated at Columbia University in 1883, and studied art under Georges Boulanger and Jules Lefebvre in Paris. He was awarded the Hallgarten Prize of the National Academy of Design in 1888. Among his works are the mural painting *The Canterbury Pilgrims* in the great hall at Georgian Court, Lakewood, N. J., and *The Story of Psyche,* a series of lunette decorations in the palmroom at the Saint Regis Hotel, New York.

SEWELL, William Joyce, American statesman: b. Castlebar, Ireland, Dec. 6, 1835; d. Camden, N. J., Dec. 27, 1901. He came to the United States in 1851, served as a sailor for a time and later engaged in business. He commanded a brigade at Chancellorsville, where he led a brilliant charge and was badly wounded. He was wounded also at Gettysburg, and served creditably on other battlefields. At the close of the war he was brevetted brigadier general and major general. He was interested in railroad affairs after the war; was elected to the New Jersey Senate in 1872, and was president of that body in 1876, 1879 and 1880. He was United States senator from New Jersey in 1881–1887 and 1895–1901. In 1899 he became major general of the New Jersey National Guard.

SEWELLEL, sē-wĕl'ĕl, a terrestrial rodent which is formed into a family by itself (Aplodontiidae), and regarded as a connecting link between beavers and squirrels. It is represented by a single species *Aplodontia rufus,* restricted to "a small area on the west coast of North America, in Washington, Oregon and California." The aborigines called it "Showt'l" or "Sewellel," the trappers the "Boomer" or "Mountain Beaver." The animal is plump, with broad head, short limbs and hardly any tail; measures about a foot in length; and has a brownish color. It lives socially in colonies, burrows underground and lives on vegetable matter. It dwells in wet places in which the vegetation is rank and dense. For its winter store it collects great quantities of woody plants and ferns, which it dries thoroughly in the sun before putting in storage for the winter. As a connecting link *Aplodon* is of much interest to naturalists, while the Indians use its skin and also its flesh.

SEWERAGE. See SANITARY ENGINEERING.

SEWICKLEY, borough, Pennsylvania, in Allegheny County, altitude 732 feet, on the Ohio River; by rail, 13 miles northwest of Pittsburgh, on the Pennsylvania Railroad. A residential suburb, it has no industries and restricts local trade to a minimum. Its name is an Indian word for "sweet water." Government is administered by burgess and council, with a borough manager. The water system is municipally owned. Pop. (1940) 5,614; (1950) 5,730.

SEWING MACHINES. The first existing description of a sewing machine is that of Thomas Saint, an English cabinet-maker. On July 17, 1790 he secured a patent on a machine to be used for "quilting, stitching, and sewing, making shoes and other articles." The specifications and drawings of the patent comprised, among other things, a crude device for forming a chain stitch. There is no evidence that Saint ever tried to introduce into practical use the mechanisms described in the patent.

In 1818, a sewing machine which made a backstitch was invented by the Rev. John Adams Dodge of Monkton, Vermont, but was neither patented nor manufactured.

The first sewing machine put into operation was patented in France, in 1830, by Barthélemy Thimonnier. By 1831 Thimonnier had 80 of these machines, which were made of wood, turning out clothing for the French Army. A mob of infuriated tailors, afraid of losing their livelihood because of this new invention, destroyed every one of the machines. Thimonnier kept working to improve his invention, and in 1850 he took out an American patent for a metal sewing machine. However, his efforts did not gain much recognition and he died in 1857 a poverty-stricken man.

Sometime between 1832 and 1834, Walter Hunt, one of the most prolific American inventors of his day, made a sewing machine which combined some of the essential parts of present-day models. His invention had a needle with an eye near the point, attached to the end of a vibrating arm. A loop was formed beneath the cloth by the needle thread, through which moved a shuttle reeling off another thread and making an interlocked stitch. Hunt did not patent his invention at this time and only built two machines. When, in 1853, he tried to secure a patent, he was unable to get one on the grounds that he previously had not applied for a patent and his invention, therefore, did not legally anticipate the patent granted to Elias Howe, Jr., in 1846.

Howe began his attempts to build a sewing machine in 1843. By 1845 he had built a machine which worked, and Howe gave public demonstrations to prove its superiority over hand sewing. But he was not able to get a single order for his machine. On Sept. 10, 1846, he received his first patent. Howe was the first person to patent a machine which combined the eyepointed needle with a shuttle for forming a stitch. His machine also had an intermittent feed for holding and carrying the material forward as each stitch was formed. The mechanical device for the feed was called the "baster-plate" and the length of the seam at one operation was determined by the length of the plate. Since Howe's machine at first met with no commercial success in the United States, he decided to try his luck in England. He was able to arrange an agreement with an English manufacturer, William Thomas, by the terms of which Howe was to receive a small

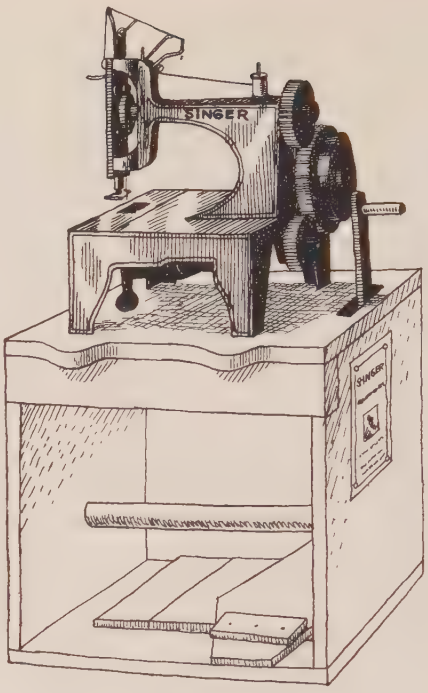
downpayment and a royalty on each machine sold in England. He was also to work for this manufacturer to adapt his machine to the making of corsets. Howe soon found it impossible to work for Thomas and he never received his royalties. In 1849 Howe came back to the United States to find that the sewing machine was arousing the public's interest and that several people were making machines which Howe believed infringed his patent. He thereupon launched a series of suits to protect his patent.

In 1847, Allen B. Wilson, then working as a cabinet-maker in Adrian, Michigan, conceived the idea of a sewing machine, although he had never heard of one. He did not complete full drawings of his machine until the latter part of 1848. On Feb. 3, 1849, he began the construction of his first model, which he completed in about 60 days. This machine made the lock stitch, the lower thread being carried by a double pointed shuttle. Wilson's machine contained the first automatic feed movement ever produced. This was called the "two-motion feed" which consisted of a horizontally reciprocating tooth surface (the pitch of the teeth being forward) engaging the material at all times, and while the needle was in the material moving back to take a new stroke. Wilson patented this machine on November 12, 1850. He next turned to a substitute for the shuttle, and he produced the rotary hook for forming the lock stitch between the upper and lower threads. This device, based on completely different mechanical principles than the shuttle, was patented on August 12, 1851.

It is a remarkable coincidence that on the same day a patent was granted to Isaac M. Singer for his first machine. The main features of the Singer machine were its straight needle, working at the extremity of a stationary overhanging arm, and its feed, consisting of a roughened wheel. A straight shaft in the overhanging arm imparted the motion to the needle, and the shuttle was driven in its race below the feed table by a mechanism deriving its motion from the shaft by means of tooth gearing. The feed consisted of an iron wheel with a corrugated surface, the top of which was slightly elevated above the level surface of the table. By an intermittent motion the feed carried the cloth forward between stitches without injury to the fabric. This device permitted the cloth to be turned in any direction by the operator while sewing, which was impossible with the styles of feed which perforated the goods. The material was held in place by a presser foot alongside the needle. This presser foot embraced an important feature possessed by no other sewing machine up to that time—the yielding spring which would permit the passage over seams, and adjust itself automatically to any thickness of cloth.

In the same year, 1851, William O. Grover and Baker patented a two-thread chain stitch machine. The stitch was made by a combination of circular reciprocating under-needle and a curved upper-needle with an eye near the point. This eliminated both shuttle and bobbin and made it possible for the upper and under threads to be taken from commercial spools.

On Dec. 19, 1854, a patent was issued to Wilson for his celebrated "four-motion feed." This is a device in which the flat-tooth surface of the feed, being in contact with the cloth, is moved forward, carrying the cloth with it; then drops out of contact with the cloth, is moved backward



The first Singer machine, patented 1851.

and then rises up against the cloth and is again ready for the first motion. This invention solved the problem of a practical feed, was soon generally adopted, and has become the feed motion of all makes of sewing machines.

In 1854, Elias Howe started to garner the fruits of his long legal battles. He won a verdict against the Singer Company, covering the use of the eyepointed needle. As a result of this victory and subsequent verdicts over the Wheeler & Wilson Company, and the firm of Grover and Baker, Howe was able to collect a royalty of $25 for every sewing machine that was manufactured. However, when Howe tried to improve his machine he was sued by the others for infringing their patents. To eliminate this perpetual legal warfare, the above-mentioned manufacturers decided to set up a patent pool covering all the main features of their sewing machines. An agreement was reached which provided that the pool was to license other manufacturers for a royalty of $15 per machine. Howe was to receive an equal share of the profits from this licensing system, and in addition he was to receive a royalty of $5 for every machine sold in the United States and $1 for every machine exported. Howe is estimated to have received close to $2,000,000 for this agreement. In 1860, the combination cut its license fee from $15 to $7, and Howe's royalty was reduced to $1 per machine. The patent pool broke up in 1877.

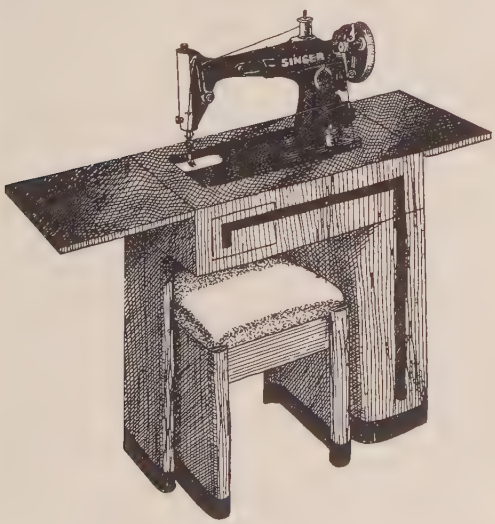
The next machine to be put on the market was the Willcox & Gibbs. This machine, which had a rotating hook for using a single thread to make the twisted loop-stitch, was first patented in June, 1857 by James Gibbs, a farmer of Millpoint, Va.

The first sewing machines were designed primarily for factory use, and it is in this field that these machines have made their greatest impact and have reached a very high level of technological development. After the Civil War,

there was a switch-over from hand to machine-sewn clothing. In 1866, an overcoat which formerly took 6 days to be sewn by hand could be sewn in 3 days by a machine. The first electrically-powered sewing machine was exhibited at the Paris Exposition in 1867, and by 1905 electric machines were an important factor in the manufacturing trades.

In the 1920's a machine was produced which was equally adaptable to sewing coat pads, embroidering, attaching lace, stitching window blinds, hat bands, and coat collars, tucking shirts and blouses, seaming shoe heels, binding woolen blankets, and ornamenting ladies' gloves. The latest industrial machines can work as fast as 5,000 stitches per minute. In 1948, the Singer Company produced an electronic machine which seams plastic film materials by means of high frequency current. There are over 4,000 types of industrial sewing machines. They are used in the manufacture of such products as life belts, parachutes, awnings, books, mens' and boys' clothing, corsets, curtains, rugs, gloves, hats, hosiery, luggage, pocketbooks, flags, sails, shirts, shoes, baseball gloves, tents, underwear and upholstery.

The introduction of electric power was a very important development in the field of home sewing machines. The first electric home machine was put on the market in 1889 but it was not until the 1920's that this machine came into widespread use. Since that time over 90 per cent of the machines sold in the United States have been electric-powered. Indicative of the improvements in home machines is the fact that whereas early machines approximated 200 stitches per minute, the latest models sew at the rate of 1,500 stitches per minute.



Typical modern sewing machine.

Almost all modern home sewing machines make the lock stitch. This stitch, which consists of an upper or needle thread and an under or bobbin thread locked together in the material, is made in the following manner: The eye-pointed needle goes through the material. As the needle starts to rise a loop of thread is formed. In the shuttle-type machine, the loop is immediately entered by a shuttle containing a bobbin of under thread. The shuttle thread is enclosed in the loop of needle thread and both threads are then drawn up by the action of the thread take-up lever and the stitch is tightened. In the rotary hook-type machine, the loop of thread is taken by the point of the hook and is passed around the bobbin case containing the bobbin of under thread, and is enclosed by the needle thread and both threads are then drawn up by the action of the thread take-up lever and the stitch is tightened.

In 1947 the Necchi machine, made in Italy, and in 1949 the Pfaff machine, made in Germany, came onto the American market. These machines embody an important development. Previously in order to do special work such as button-holing, darning, mending, embroidery, monogramming, etc., it was necessary to buy special attachments for home machines. However, with the Necchi and the Pfaff, by moving a lever or turning a dial, the needle is readjusted so that it can do the zig-zag sewing required for the special work.

SEX DEVIATIONS, sometimes called sexual aberrations, have concerned mankind almost from earliest recorded history. It is customary to refer to persons exhibiting what we are pleased to call sexual deviations, or departures from what modern society agrees to be normal, as sex perverts. Many persons, otherwise well informed, in their own minds have arranged these irregularities in various categories and speak of them casually as perverts, sexual psychopaths, sex neurotics, and so on, oftentimes without understanding very clearly the condition to which they refer. The object in this short article is to condense the subject, covering the main points in an effort to clear this misunderstanding.

Our social customs seem to compel society to look upon a sex deviate as one bringing disgrace to his family, and the admission to a gathering of normal people, of a homosexual, an outrage. This is because normal expression of sex feelings is supposed to be possible only between persons of the opposite sex. In other words, heterosexual relations, even if adulterous, are normal while homosexual ones are not. It should be understood clearly that homosexual persons are quite likely to be entirely normal mentally and are generally harmless. It is true that some deviations tend toward the criminal side and are coexistent with dementia precox, but the sex deviation is not dependent on the mental condition. Such major aberrations as sadism, rape, and indecent exposure are regarded as assaults upon society and offenders are liable to punishment. Sexual disorders are common, and by disorder is meant here a departure from the normal sexual goal for which men and women ordinarily strive. It is difficult to state exactly what the normal goal is, since sex relations can vary from excessive ecstasy to solemn frigidity and still be considered as within normal limits. It is only when normal impulse is denied that many persons seek satisfaction with one of the same sex. This denial may be social, or due to incarceration, or isolation, but is a manifestation of neurosis. Sex deviation is always a social phenomenon and divergence in one group or era is not always so elsewhere. There is hardly a type of sex custom that has not, in history, been forbidden at one time or another. It has been said that sex regulation is always conventional and never natural and certainly no law or

regulation was ever made to govern sex conduct that did not prove burdensome to great numbers of people. Nor have violations of such law and regulations failed to occur. To cite examples of the morality of yesterday which has become the immorality of today, marriage between brother and sister was common and even compulsory among the sovereign rulers of some ancient civilizations, who had never heard of incest. Even pederasty in many Eastern countries was considered a harmless amusement. Such abnormal conduct as flagellation, exhibitionism, the wearing of women's apparel by males, and like behaviorisms, while regarded with disfavor in Western civilizations, are looked upon elsewhere as not improper. Such examples have been mentioned to emphasize the fact that in the evolution of mankind, no single normal standard has ever existed that can be made to apply to civilization as a whole. It is impossible in studying sexual behavior to ignore the mammalian instinct. Thus "perversions" have even been observed in animals and there are such things as homosexual animals. This can be understood if we realize that sexual excitement seizes and accepts gratification wherever it can be found.

The historical background of various types of sex deviation furnishes much information on the subject. Among primary sex aberrations mentioned in ancient history are some well recognized entities. Lesbianism or the sexual love of one woman for another is now known as homosexuality in the female and also as Sapphism after the Greek poetess who lived in Lesbos. It is also called inversion. The term uranism is still used to denote a male with homosexual tendencies. It is a common belief that male homosexuals are lacking in virility and sexual development. What is lacking is frequently not development nor ability, but a desire for the opposite sex and this desire is developmental and not under control of the individual. Pederasty is the sexual love of men for boys. This was a widespread behaviorism in ancient Greece. Some of the greatest and strongest men in history have had at least homosexual tendencies, while many of the cruelest tyrants actively and openly exhibited their homosexualities. Among them were Tiberius and Nero. Sex deviations where animals have been involved have always been regarded with horror and have been punished as grave crimes even with death, as is prescribed in the Bible. In the Middle Ages the guilty person was burned alive. The use of the whip for punishment, either parental, religious, or judicial, has long been recognized. Flagellation, or the act of whipping, to produce gratification is as old as Roman history. Religious flagellation, not immoral in itself, was often used as a cloak to disguise the sadistic gratification of sexual deviants who lashed or were lashed for their own satisfaction. The development of sex impulses according to Sigmund Freud (1856–1939) begins in young children who, from birth, have a distinct sex life. Before the time of Freud it had been assumed that sex life began only at puberty. In the study of children we should probably substitute the term "desire" for the expression "sexual satisfaction," when discussing the sex life of the child. All children explore not only their sex organs but all portions of the body and take delight in experimenting with their body orifices, such as the ears, mouth, nose, vagina, and rectum. Touch, contacts, fondling, kisses, nursing, etc., all contribute to sexual excitement. A child has no sense of shame; even bed wetting and defecation are sources of interested satisfaction. Everything the child does is for his own pleasure and this self-love or narcissism, if uncontrolled, persists into adult life. Our habit demands a stronger suppression of sex impulse than of hunger. No one is ashamed of being hungry but not always is it possible to admit a craving for sex. As an individual grows older and curbs are placed upon him, sexual repressions accumulate and cause discomfort. These are often unrecognized for what they are and eventually the condition shows itself in a series of neurotic symptoms (sex neuroses). Much interest attaches to the cause of sex deviations especially homosexuality. This has been long debated and it has been classed as congenital and also as hereditary. It has been observed that most homosexuals regard themselves as normal and that only about one fifth make any fight against the craving. In the past, there have been some proponents of the theory of a "third sex" in which there is a tendency to bisexual development. Psychoanalysis at last revealed the true mechanism of the homosexual and has established as a fact that all homosexuals are probably heterosexual (having a normal craving for the opposite sex) early in life, but that homosexual tendencies and development in the male can be traced often to the strong mother attachment which persists in the adult. This is known as the Oedipus complex and is a frequent cause of sexual neurosis. A similar attachment between a girl and her father is known as the Electra complex. The application of the Oedipus complex is not simple and it can be understood thoroughly only by a study of case histories (see the bibliography). Homosexuality is somewhat more common in men than in women. The deviation including those with homosexual tendencies (inactive) form a considerable segment of the population, perhaps more than 5 per cent. While the ordinary uninformed individual conceives the abnormality as found principally in men of the "sissy" type the tendency is well concealed and in general is unsuspected. The homosexual, however, knows where his counterpart is to be found. Women especially may exhibit all degrees of homosexuality from an inactive and suppressed desire to fondle other women up to active participation where they seek out women and test their response to an approach. Many women limit participation to hugging and kissing while others are satisfied only by mutual sex gratification through physical contact within the privacy of the bedroom. It should be emphasized that many homosexuals of both sexes marry and have families and still remain deviates in their desire. Such unions are usually not particularly happy and are responsible for many divorces. Masochism is the counterpart of sadism and can be defined as sexual enjoyment attained from receiving bodily pain or humiliation from another. Fetishism is a form of sexual deviation in which the person's *libido* or sexual energy is attached to something that is a symbol of the love object. It is a symbolic obsessional form of sex gratification. The attachment may be to a woman's glove, shoe, handkerchief, undergarment, etc. Transvestism is a form of sex deviation in which a person attempts to play the role of one of the opposite sex by what is called

"crossed dressing." Such a condition has resulted sometimes from punishment inflicted on a young boy by forcing him to wear girl's clothing. Among miscellaneous deviations are cases of aberrations characterized by an intense desire to commit filthy and indecent acts. Some of these are the result of faulty and vicious upbringing in which the parents have been promiscuous and where this has been observed by the child. Poverty, abnormal life of the mother, such as prostitution, and many other early influences of an adverse character produce unfortunate results in the child. These unclean acts including coprophilia (obscene language) may verge on a psychosis. Children usually outgrow the practice of obscene writing on walls and toilets but this, including foul language used over the telephone, if present in adults, goes beyond mere sex irregularity and is harmful to society. Another form of deviation, also a psychosis, is the love manifested for a statue or model. Cases have been reported where a manikin was actually taken to bed, named, and endowed with personality by the person affected. This is known as Pygmalionism, from the Greek legend of a sculptor-king of Crete, Pygmalion, who fell in love with an ivory statue of a maid. Cannibalistic traits and vampirism are manifested by a desire to bite and tear human flesh or to drink human blood and have their origin in a desire for sex gratification. These are sometimes listed in police reports as mayhem. Even kleptomania (compulsory desire to steal) has its roots in sexuality, although it is actually a psychological disorder. Often the objects stolen have a symbolic value. Such shocking crimes as sex-murder, rape, and mutilation are sadistic acts once more common than is the case today and are atavisms seen occasionally in a civilized age. Deviations occurring in large groups of people are sometimes referred to as sex orgies. Most of those taking part are victims of sexual maladjustment and may be latent homosexuals. In many cases they are immature and exhibit adult infantilism. Exchange of wives on week-end frolics or where the husband derives pleasure from giving his wife to another are referred to as cases of pluralism. Hairclipping is a form of compulsive fetishism in the same class as exhibitionism and indecent exposure. While it may cause great alarm it is attended usually without other molestation. It should be noted that such compulsive acts including the serious acts of aggravated assault, mutilation, and even murder, are often committed in the face of the greatest risk of detection of the offender who will, in many cases, continue his course until apprehended.

Philandering, bigamy, and polygamy are common in our society and are known as behaviorisms or departures from a normal code of living. Those involved are nearly always sexually maladjusted.

To recapitulate, the sexual deviate gratifies in adult life the erotic desires of childhood and persists in living in his sexual past. Sex deviations are probably not actual disease entities but are symptoms of an underlying obsessional neurosis. Some are transitory and are amenable to proper treatment and some are not. Certainly not all sexual deviations can be classed as abnormal. Society should not adhere to the dogma that all sexual deviates should be shut up as a danger to society. For some thousands of years society has had to cope with the problem of sex abnormalities and it is incorrect to refer to homosexuality, for example, as a new and modern menace to our social order. It should be realized, to draw upon the language of some of those who are experts on the subject and have had unusual opportunity for observation, that perhaps some 90 per cent of persons have been guilty of "deviation," if we can always call it by that name and a large percentage of those have committed some act which, under a strict application of some law, could have brought him into a police court.

Any discussion of treatment in detail has no place in this article. It should not as a rule be attempted by one who has limited experience in handling cases which are best referred to a psychologist. Psychoanalysis and suggestion after a complete and exhaustive overhaul of the mental attitude of the patient, with prolonged and regular care, offers the best hope of success.

SEXAGESIMA, sĕks-ă-jĕs'ĭ-mă, **SUNDAY,** the second Sunday before Lent. See Quinquagesima.

SEXTANT, sĕks'tănt, a portable instrument for measuring the altitudes of the heavenly bodies above the horizon, or their angular distance as seen in the sky. It was invented independently by Thomas Godfrey, of Philadelphia, and Captain Hadley of the British Navy, about 1730. The principles on which it works will be seen by a study of Fig. 1. C is a plain flat mirror, of which the polished side is turned downward and toward

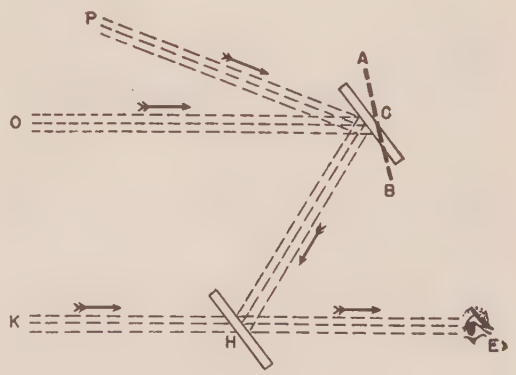

Fig. 1.

the left. H is a flat plate of polished glass through which an eye placed at E may view a distant object in the direction K by light coming through it in the direction of the dotted lines. Light emanating from another object O or P and falling on the mirror C will, where the mirror is properly directed, be reflected along the line CH and, in striking the glass plate H, a certain portion of it will be reflected in the direction HE, so that the observer with his eye at E will see both the objects K and O or P in coincidence. If the mirror C is set parallel to H as in the figure, the rays KE and OC will be parallel, and may, therefore, be considered as emanating from the same object at an infinite distance.

Thus the eye will see two images in the mirror as if together. But if the mirror C be moved into a different direction, that shown by the dotted line AB for example, the direction of the ray, the direction of the line PC, the rays along which are reflected to H, will deviate from OC by double the angle through which the mirror has turned. This doubling is caused by the fact that the angles of incidence and reflection are both changed by the motion of C. It follows that if the observer can measure the angle between the mirror C and H, doubling this angle will give him the difference of direction between the rays coming from K and from P .

The sextant is used to measure this angle. The essential parts of it are shown in Fig. 2. The part ABC consists of the arc AB round C as a center and firmly fastened by the radii CB and CA which are again firmly connected by a framework not shown in the figure. To this framework is attached the fixed plate of glass H, of which the lower half is silver while the upper half is transparent. T is a telescope, also firmly fixed to the frame, through which the eye looking in at E may see a distant object

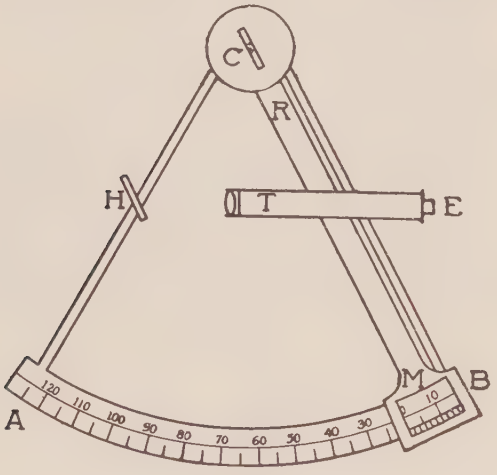

Fig. 2.

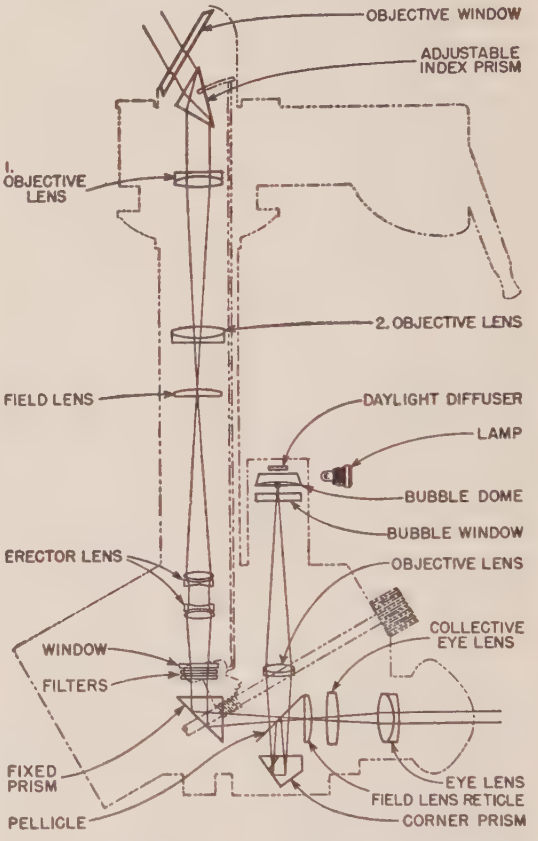
through the transparent portion of the mirror, and at the same time see any other object by the light reflected from the silvered part. The arc AB is graduated to degrees and fractions as shown by the figures. Owing to the doubling of the angle, the measures on the arc BA are also double. That is to say, this arc is only 60 degrees in length, but is divided into 120 degrees, so as to show the actual altitude of the object observed.

RM is a movable arm carrying a mirror C called the index glass, fixed to it perpendicularly at its upper end. The arm revolves around C as a center. At its lower end there is an index mark and vernier by which the position of the arm with respect to the graduations on the arc may be determined.

The altitude of a heavenly body at C is then measured by the observer taking the instrument in his hand and holding it in a vertical position, with the telescope ET horizontal, so that the sea horizon may be seen through the transparent part of the horizon glass H. The observer facing in the vertical plane of the sun or other object then turns the arm RM around the center C until he brings the sun into sight, through its rays being reflected first from C and then from H. When the limb of the sun is thus made to coincide with the horizon, the angle through which the arm RM has moved from parallelism is shown by the position of the index on the graduated arc BA, which is then determined by the vernier.

In ordinary use the navigator never has to measure angles exceeding 90°. In this case the arc BA need only to be 45 degrees in actual length. The instrument is then called an octant. This was the original form used by Hadley.

"For very accurate use the arc is extended down so as to form a complete circle. A special device is employed to bring about the proper reflection of the light; but the reflecting circle, as the instrument is called, is too complicated to admit of common use by the navigator."



Bubble sextant.

Bubble Sextant.—Aircraft sextants, designed to perform the same function as marine sextants, actually differ from the latter in many significant ways because of the conditions of their employment. The natural horizon is very seldom visible for use as the celestial navigation reference in aircraft. A gravity-responsive element, such as a circular bubble is, therefore, incorporated into the optical system to serve as an "artificial horizon." Such a gravity-responsive device, however, also responds to any other acceleration, and, because accelerations constantly accompany even the straight and level flight of aircraft, a single observation made against such a reference could be in error by 150 miles owing to its momentary deviation from the true vertical. Therefore, the average of several observations is performed by mechanical means over a period of one or two

minutes, and, under normal flying conditions, achieves an accuracy within five to eight miles.

The latest standard sextant is periscopic, a form demanded by the speed and altitude of modern aircraft which deprive the crew of observation windows or domes. The periscopic sextant permits observations from +10° to +92° altitude through 360° in azimuth through a 1⅜ inch diameter tube, extending 1½ inches above the skin.

An outline of the sextant is reproduced below with its more important optical elements labeled. The index prism performs the same function as the mirror, C, of the marine sextant, being rotatable, its angle indicating the altitude of the celestial body. A knob in the body of the sextant controls the prism rotation via a worm, sector gear, and rod linkage (indicated by dotted line) and is coupled to a counter (not shown) which gives the altitude of the object directly in degrees and minutes. The path of light from the object is traced through the objective and erecting systems, the fixed prism which directs the light to the horizontal eyepiece and the focusable eyepiece. The bubble is in a transparent chamber mounted next to the objective tube and is illuminated by daylight or a lamp. Its image passes through a lens to a corner reflector prism and back to a beam splitter, whence a portion of the light is reflected into the eyepiece. An observation is obtained by rotating the prism until the image of the object lies inside the center of the bubble image.

The sextant is maintained in a gimballed mount attached to the aircraft, containing a shutter which is closed when the sextant is not installed. This mount offers the periscopic sextant a unique advantage over any hand-held sextant, in that is is capable of positive azimuthal positioning. With a rotatable compass rose in the mount, the sextant can be used to measure relative bearings and can thus check the aircraft magnetic compass by obtaining true heading. In this employment it replaces another aircraft instrument normally required, the astrocompass.

SEXTET (from Lat. *sextus*, sixth), *in music*, is a composition for six voices or instruments, or for voices with instrumental accompaniment. Instrumental sextets are generally compositions in sonata form.

SEXTON, Frederick Henry, Canadian engineer and educator: b. New Boston, New Hampshire, June 9, 1879. He was educated at the Massachusetts Institute of Technology, and was professor of metallurgy there, 1901–1902. He was research metallurgist, General Electric Company, Schenectady, N. Y., 1902–1904; assistant professor of mining and metallurgy at Dalhousie University, Halifax, Nova Scotia, 1904–1906; and president of the Nova Scotia Technical College from 1906 to 1947. He was also regional director for Nova Scotia, of Canadian Vocational Training, 1940–1947. He is author of many technical papers.

SEXTON, a church officer whose duties consist in taking care of the church generally, to which used to be added the duty of digging and filling up graves in the churchyard, when the church had a cemetery attached to it. In the United States the sexton is also very often an undertaker, and thus continues in a form different from the old-time sexton, to attend to the interment of church members. The term sacristan, of which sexton is a corruption, applies more particularly to an official in the Roman Catholic and Anglican churches, who has charge of the sacristy and its contents, and of the vestments worn during the service. He occupies a considerably higher rank than the ordinary sexton, and in English cathedrals is often a minor canon.

SEXTUS EMPIRICUS, sĕks'tŭs ĕm-pĭr'ĭ-kŭs, Greek physician and skeptic, who flourished in the first half of the 3d century. He lived at Alexandria and Rome. Skepticism appears in his writings in the most perfect state which it reached in ancient times. We have two works by him, written in the Greek language, and they are the source of our knowledge of the Greek skeptical philosophy. One of them entitled *Outlines of Pyrrhonism* in three books, explains the method of Pyrrho; the other, entitled *Against the Mathematicians,* is an attempt to apply that method to all the prevailing philosophical systems and other branches of knowledge.

SEXUAL SELECTION, a term used by Darwin to denote a special phase of natural selection, depending on a competition between rival males, in which a premium is set on those qualities which favor their possessors in securing mates. This competition takes two forms: On the one hand, rival mates, for instance, stags or gamecocks, fight with one another and the conquerors have naturally the preference in mating; on the other hand, rival males sometimes seem to vie with one another in displaying their attractive qualities before their desired mates, who, according to Darwin, choose those that please them best. Darwin gives the following summary of his theory:

"It has been shown that the largest number of vigorous offsprings will be reared from the pairing of the strongest and best-formed males, victorious in contests over other males, with the most vigorous and best-nourished females, which are the first to breed in the spring. If such females select the more attractive and, at the same time, vigorous males, they will rear a larger number of offspring than the retarded females, which must pair with the less vigorous and less attractive males. So it will be if the more vigorous males select the more attractive and, at the same time, healthy and vigorous females; and this will especially hold good if the male defends the female, and aids in providing food for the young. The advantage thus gained by the more vigorous pairs in rearing a larger number of offspring has apparently sufficed to render sexual selection efficient."

In regard to the second aspect of sexual selection, in which the females are believed to exercise some choice, giving the preference to those suitors which have brighter colors, more graceful forms, sweeter voices or greater charms of some kind, there is no little difference of opinion. Darwin indeed believed strongly in the female's choice and referred to this process of selection many of the qualities which distinguish male animals. The females "have by a long selection of the more attractive males added to their beauty or other attractive qualities." On the other hand, Alfred Russel Wallace maintains a very different position. "There is," he says, "a total absence of any evidence that the females admire or even notice the display of the males. Among butterflies there is literally not one particle of evidence that the female is influenced by color or even that she has any power of choice, while there is much direct evidence to the contrary." Against this, G. W. and E. G. Peckham, in their careful essay on sexual selection in

spiders state that they have in the *Attidae* "conclusive evidence that the females pay close attention to the love dances of the males and also that they have not only the power, but the will, to exercise a choice among the suitors for their favor." Some observers of birds are also confident that the females choose the more musical or otherwise attractive males. But again Wallace maintains that the fact that every male bird finds a mate "would almost or quite neutralize any effect of sexual selection of color or ornament; since the less highly colored birds would be at no disadvantage as regards leaving healthy offsprings."

The theory of sexual selection is of considerable importance in a general theory of evolution. This may be illustrated in reference to the bright plumage of many birds. If we postulate successive crops of variations (which cannot at present be completely rationalized), if we acknowledge that there is really "preferential mating" among birds (which is not readily proved or disproved), if we believe that the females are sensitive to the slight excellences which distinguish one suitor from another and that their choice of mates is determined by these excellences (which A. R. Wallace emphatically denies), then we may say that the greater brightness of male birds may have been evolved by sexual selection. This was Darwin's opinion. The brighter males succeeded better than their rivals in the art of courtship; the variations which gave them success were transmitted to the offspring; gradually the qualities were established and enhanced as secondary sexual characters of the species. But Wallace interpreted the facts quite otherwise. The relatively plain plumage of the female birds was due to natural selection, eliminating those whose conspicuousness during incubation was fatal, fostering those whose coloring was protective. Just as Daines Barrington, a naturalist, still remembered as the correspondent of Gilbert White, suggested (1773) that singing birds were small and hen birds mute for safety's sake, so Wallace maintained that female birds had forfeited brightness as a ransom for life.

The doubts and difficulties arouse skepticism as to the thoroughness of the explanations of secondary sexual characters suggested either by Darwin or by Wallace. It is not surprising therefore, to find St. George Mivart's explanation of the beauty of males as the direct expression of an internal force, or Paolo Mantegazza's hints as to physiological explanation of the sexual divergence, or W. K. Brook's reference to "something within the animal which determines that the male should lead and the female follow in the evolution of new breeds." P. Geddes advanced further, endeavoring to interpret the secondary sexual characters as outcrops of the relative preponderance of anabolism and katabolism characteristic of females and males respectively. Gay coloring—sometimes at least due to pigmented waste products—is regarded as a characteristic expression of the predominantly katabolic or male sex and quiet plainness is equally natural to the more anabolic females. But this theory, which seeks to rationalize the variations which Darwin simply postulated, is by no means inconsistent with a recognition of sexual selection as an accelerant directive process in the evolution of male brightness, or of natural selection as a retardative directive process eliminating disadvantageously conspicuous females.

Wallace in his later works advanced toward a rational interpretation of the variations which he was previously content to postulate as facts. For he says that "ornament is the natural outcome and direct product of superabundant laws of growth and development." It seems to some that this mode of interpreting characters is of far-reaching importance and that it affects not only the theory of sexual selection but that of natural selection as well.

To sum up, the problems involved in sexual selection are (1) what physiological conditions explain the secondary sexual characters which so often distinguish males and females; (2) to what extent has sexual selection guided the differentiation of the sexes alike in distinctive qualities and in aesthetic sensitiveness? Before these problems can be adequately solved many more facts must be accumulated.
